ICF International. 2016. Venice Auxiliary Pumping Plant Project. Draft Environmental Impact Report. October. (ICF 00476.15.) Los Angeles, CA. Prepared for City of Los Angeles Department of Public Works, Bureau of Engineering, Los Angeles, CA.

Table of Contents

Executive Summary **ES-1**
Introduction and Background ES-1
Proposed Project Summary ES-2
Project Objectives ES-2
Project Characteristics ES-2
Project Schedule ES-3
Required Approvals ES-3
Comments Received on the Notice of Preparation ES-3
Issues Raised ES-6
Issues to Be Resolved ES-11
Summary of Environmental Impacts ES-11
Impacts Determined to Require No Further Consideration in This EIR ES-11
Impacts Determined to Be Less than Significant ES-11
Significant Unavoidable Impacts ES-12
Cumulative Impacts ES-12
Significant Irreversible Environmental Changes that Would Be Caused by the Proposed Project Should It Be Implemented ES-12
Growth-Inducing Impacts ES-13
Alternatives and the Environmentally Superior Alternative ES-13
Summary of Impacts and Mitigation Measures ES-14

Chapter 1 Introduction 1-1
1.1 Background and Project Overview 1-1
1.2 Purpose and Intended Use of This EIR 1-2
1.3 Scope and Content of the Draft EIR 1-5
1.3.1 Notice of Preparation/Initial Study 1-5
1.3.2 Public Outreach Efforts 1-6
1.4 Responsible and Trustee Agencies and Project Approvals 1-7
1.5 Organization of the Draft EIR 1-7
1.6 Related Projects 1-8
1.6.1 Venice Dual Force Main 1-8
1.6.2 VPP Manifold Replacement Project 1-8
1.6.3 Venice Pumping Plant Generator Replacement 1-9
1.7 Key Principles Guiding Preparation of This Draft EIR 1-9
1.7.1 Forecasting 1-9
1.7.2 Reliance on Environmental Thresholds and Substantial Evidence 1-9

1.7.3 Disagreement Among Experts 1-9
1.8 Review of the Draft EIR 1-12
Chapter 2 Project Description 2-1
2.1 Project Objectives 2-1
2.2 Project Location 2-1
2.3 Environmental Setting 2-2
2.4 Surrounding Land Uses 2-3
2.5 Land Use Designation and Zoning 2-3
2.6 Background 2-3
2.7 Project Overview 2-5
2.8 Proposed Project 2-5
2.8.1 Operational Requirements 2-5
2.8.2 Aboveground Facilities 2-6
2.8.3 Parking 2-7
2.8.4 Public Art 2-7
2.8.5 Belowground Facilities and Diversion Structure within the Grand Canal 2-7
2.8.6 Odor Control 2-8
2.8.7 Utilities and Services 2-8
2.8.8 Landscaping and Drainage 2-9
2.8.9 Site Security 2-9
2.8.10 On- and Off-site Circulation, Parking, and Pedestrian Access 2-9
2.8.11 Open Space 2-10
2.8.12 Operations and Maintenance 2-10
2.8.13 Construction 2-10
2.9 Relationship to Other Projects 2-13
2.9.1 Venice Dual Force Main 2-13
2.9.2 VPP Manifold Replacement Project 2-13
2.9.3 Venice Pumping Plant Generator Replacement 2-13
2.10 Responsible Agencies and Project Approvals 2-13
2.11 Project Schedule 2-15
Chapter 3 Environmental Impact Analysis 3.1-1
3.1 Aesthetics 3.1-1
3.1.1 Regulatory Setting 3.1-1
3.1.2 Environmental Setting 3.1-6
3.1.3 Environmental Impact Analysis 3.1-9
3.1.4 Mitigation Measures 3.1-26
3.1.5 Significant Unavoidable Adverse Impacts 3.1-27

3.1.6 Cumulative Impacts 3.1-27
3.2 Air Quality 3.2-1
3.2.1 Regulatory Setting 3.2-1
3.2.2 Environmental Setting 3.2-10
3.2.3 Environmental Impact Analysis 3.2-13
3.2.4 Mitigation Measures 3.2-27
3.2.5 Significant Unavoidable Adverse Impacts 3.2-28
3.2.6 Cumulative Impacts 3.2-28
3.3 Biological Resources 3.3-1
3.3.1 Regulatory Setting 3.3-1
3.3.2 Environmental Setting 3.3-5
3.3.3 Environmental Impact Analysis 3.3-9
3.3.4 Mitigation Measures 3.3-18
3.3.5 Significant Unavoidable Adverse Impacts 3.3-19
3.3.6 Cumulative Impacts 3.3-20
3.4 Cultural Resources 3.4-1
3.4.1 Regulatory Setting 3.4-1
3.4.2 Environmental Setting 3.4-5
3.4.3 Environmental Impact Analysis 3.4-14
3.4.4 Mitigation Measures 3.4-19
3.4.5 Significant Unavoidable Adverse Impacts 3.4-19
3.4.6 Cumulative Impacts 3.4-19
3.5 Geology and Soils 3.5-1
3.5.1 Regulatory Setting 3.5-1
3.5.2 Environmental Setting 3.5-2
3.5.3 Environmental Impact Analysis 3.5-5
3.5.4 Mitigation Measures 3.5-9
3.5.5 Significant Unavoidable Adverse Impacts 3.5-11
3.5.6 Cumulative Impacts 3.5-11
3.6 Greenhouse Gas Emissions 3.6-1
3.6.1 Regulatory Setting 3.6-1
3.6.2 Environmental Setting 3.6-6
3.6.3 Environmental Impact Analysis 3.6-10
3.6.4 Mitigation Measures 3.6-19
3.6.5 Significant Unavoidable Adverse Impacts 3.6-19
3.6.6 Cumulative Impacts 3.6-19
3.7 Hydrology and Water Quality 3.7-1

3.7.1 Regulatory Setting....3.7-1
3.7.2 Environmental Setting....3.7-13
3.7.3 Environmental Impact Analysis....3.7-20
3.7.4 Mitigation Measures....3.7-42
3.7.5 Significant Unavoidable Impacts....3.7-42
3.7.6 Cumulative Impacts....3.7-42
3.8 Land Use and Planning....3.8-1
3.8.1 Regulatory Setting....3.8-1
3.8.2 Environmental Setting....3.8-10
3.8.3 Environmental Impact Analysis....3.8-41
3.8.4 Mitigation Measures....3.8-48
3.8.5 Significant Unavoidable Adverse Impacts....3.8-48
3.8.6 Cumulative Impacts....3.8-48
3.9 Noise and Vibration....3.9-1
3.9.1 Introduction....3.9-1
3.9.2 Regulatory Setting....3.9-6
3.9.3 Environmental Setting....3.9-9
3.9.4 Environmental Impact Analysis....3.9-13
3.9.5 Mitigation Measures....3.9-29
3.9.6 Significant Unavoidable Adverse Impacts....3.9-32
3.9.7 Cumulative Impacts....3.9-32
3.10 Transportation/Traffic....3.10-1
3.10.1 Regulatory Setting....3.10-1
3.10.2 Environmental Setting....3.10-5
3.10.3 Environmental Impact Analysis....3.10-8
3.10.4 Mitigation Measures....3.10-24
3.10.5 Significant Unavoidable Adverse Impacts....3.10-24
3.10.6 Cumulative Impacts....3.10-24
3.11 Energy....3.11-1
3.11.1 Regulatory Setting....3.11-1
3.11.2 Environmental Setting....3.11-2
3.11.3 Environmental Impact Analysis....3.11-2
3.11.4 Mitigation Measures....3.11-6
3.11.5 Significant Unavoidable Adverse Impacts....3.11-6
3.11.6 Cumulative Impacts....3.11-7
Chapter 4 Comparison of Alternatives....4-1
4.1 Introduction....4-1

4.2 CEQA Alternatives 4-1
4.2.1 No Project/No Build Alternative 4-2
4.2.2 Alternative 1 – Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade 4-2
4.2.3 Alternatives Considered but Rejected As Infeasible 4-2
4.3 Evaluation of CEQA Alternatives 4-6
4.3.1 No Project/No Build Alternative 4-7
4.3.2 Alternative 1 – Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade 4-7
4.4 Comparison of CEQA Alternatives 4-9
4.5 Environmentally Superior Alternative 4-10
Chapter 5 Other Environmental Considerations 5-1
5.1 Effects Found Not to Be Significant 5-1
5.2 Significant Irreversible Environmental Changes that Would Be Caused by the Proposed Project Should It Be Implemented 5-2
5.3 Growth-Inducing Impacts 5-3
5.3.1 Direct Population-Generating Uses 5-3
5.3.2 Growth Accommodation 5-4
5.3.3 Expansion of Public Services or Utilities 5-4
Chapter 6 Persons Consulted 6-1
6.1 City of Los Angeles Department of Public Works, Bureau of Engineering 6-1
6.2 City of Los Angeles, Department of Public Works, Bureau of Sanitation 6-1
6.3 Arcadis 6-1
6.4 City of Los Angeles, Department of City Planning 6-1
6.5 Native American Heritage Commission 6-1
6.6 Natural History Museum of Los Angeles County 6-2
6.7 South Central Coastal Information Center 6-2
6.8 U.S. Army Corps of Engineers 6-2
Chapter 7 List of Preparers 7-1
7.1 City of Los Angeles Department of Public Works, Bureau of Engineering 7-1
7.2 ICF International 7-1
7.3 Consensus, Inc. 7-2
7.4 Fehr & Peers 7-2
7.5 Watearth, Inc. 7-2
Chapter 8 References 8-1

Introduction and Background

This Environmental Impact Report (EIR) evaluates the proposed Venice Auxiliary Pumping Plant (VAPP or Proposed Project) in the City of Los Angeles community of Venice, Los Angeles County, California. Per the California Environmental Quality Act (CEQA), the City of Los Angeles (City), Department of Public Works, Bureau of Engineering (LABOE) is the Lead Agency. This Executive Summary is intended to provide an overview of the Proposed Project and its environmental effects. As noted in Table ES-1, with the exception of noise and vibration impacts generated during construction, and secondary impacts on surrounding land uses related to construction noise and vibration, all impacts would be reduced to less than significant with adherence to standard regulatory and permit requirements or implementation of identified project design features and mitigation measures. Nevertheless, despite the application of mitigation measures, construction-related noise and vibration impacts are considered significant and unavoidable. Given this condition, the City will be required to prepare findings and a Statement of Overriding Considerations (see Chapter 1, Introduction of this EIR for more details) for these remaining significant and unavoidable environmental impacts.

The City owns and operates the Venice Pumping Plant (VPP) (Pump Station No. 646), located at 140 Hurricane Street in the Los Angeles community of Venice, adjacent to the Ballona Lagoon and the Grand Canal. The VPP is the City's largest pumping plant and it is considered a critical facility for conveying sewage from its tributary area (see below). The facility was designed and built in 1957 and was last upsized and upgraded in 1987. Two duty and three backup pumps currently serve the facility. The VPP collects sewage from the City's Coastal Interceptor Sewer (CIS), which serves the communities of Topanga, Pacific Palisades, Brentwood, Venice, and Mar Vista. It also serves the City of Santa Monica and parts of Los Angeles County. Sewage is pumped south to the City's Hyperion Treatment Plant (HTP), located in Playa del Rey. Unlike other portions of the City's sewage collection and conveyance system, there are currently no diversions for bypassing the facility or associated CIS for required maintenance or in the event of an emergency. Moreover, the existing VPP is essentially built out and has no additional space for required back up pumps and associated equipment to ensure system reliability.

During dry-weather flows (no rain), the two duty pumps generally pump an average of 20 million gallons per day (mgd) of sewage. During wet-weather flows (rain), depending on conditions, all five pumps may be needed simultaneously to convey sewage influent from the collection area to the HTP. During certain years, flows during wet-weather conditions have reached 50 mgd and on several occasions, during extreme weather events (e.g., 1990s and 2000s), the flows exceeded the combined and simultaneous pumping capacity of the facility, resulting in near-miss events, which would have required emergency discharges directly to the Grand Canal and Ballona Lagoon or overflows into the surrounding street network. To address these issues, LABOE began planning and designing projects that would upgrade and enhance the CIS and VPP (see Chapter 2, Project Description of this Environmental Impact Report [EIR]), including the Proposed Project.

Proposed Project Summary

Implementation of the Proposed Project, which entails the construction of a new pumping plant adjacent to the existing VPP, would provide redundancy and ensure reliability of the sewer collection system. It would also allow the sewer system to handle extreme weather (e.g., El Niño), along with sea-level rise and corresponding and increases in groundwater levels that exacerbate infiltration conditions, both for the existing and planned conveyance system. With upgraded system redundancy and reliability, the potential for near misses and/or catastrophic system failures would be reduced. As part of the Proposed Project, a number of system improvements would be implemented both above and below ground, including a new electrical building, housing the control system and employee workstations; three new pumps and associated generator; sewer pipe connections to the CIS, including construction of a submerged diversion structure beneath the Grand Canal; and parking, public art, and green open space. Combined, the five existing pumps at the VPP and the three new pumps would have a rated capacity of 87 mgd (i.e., five duty pumps and three standby). All pumps would have a similar capacity and be functionally equivalent. Please see Chapter 2, Project Description for a more detailed description of the Proposed Project.

Figure ES-1, Project Vicinity Map, shows the location for the Proposed Project in relation to the City and adjacent cities and communities. The Project Site is within the Venice Community Planning Area and Council District 11. As noted in Figure ES-2, Project Location Map, the Project Site comprises three undeveloped residential lots located next to the existing VPP (see Chapter 2, Project Description of this EIR for addresses and Assessor Parcel Numbers). The three construction Laydown Areas that will be used for materials and equipment storage and for the construction staging during the anticipated two year construction period are also shown in Figure ES-2. The Project Site is within the Coastal Zone and therefore within the jurisdiction of the California Coastal Commission. Adjacent to the Project Site is an Environmentally Sensitive Habitat Area (ESHA), which is associated with the Grand Canal and Ballona Lagoon. The Venice Canal System is also City of Los Angeles Historic Cultural Monument No. 270 and part of the Venice Historic Canal District (ZI–2370).

Project Objectives

The Proposed Project is intended to meet the following Project objectives:

- Prevent potential impacts on human and environmental health caused by sewage spills from the existing VPP during extreme wet-weather events;
- Increase reliability to the system by providing redundancy to pumping capacity to improve system reliability and to allow regular service and maintenance activities to take place without compromising the City's ability to maintain pumping capacity and minimize the risk of sewage overflows; and
- Address future risks related to climate change, including increased storm intensities and sea-level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP.

Project Characteristics

The Proposed Project would be built on three vacant lots with a total combined area of approximately 12,076 square feet. As shown in Figure ES-3, Site Plan, the Proposed Project would include a number of improvements:

Figure ES-3
Site Plan
Venice Auxiliary Pumping Plant Project

- One building, two stories and approximately 32 feet in height, with a total of 2,500 square feet, that will house the operational control center for the plant, related electrical equipment, and employee workstations;
- Three 18- million-gallon-per-day (mgd) submersible pumps, constructed underground;
- Electrical equipment, uutility connections, instrumentation and controls, transformers, and generators;
- A 17- by 17-foot submerged diversion structure on the CIS, the top of which would be below the lowest elevation of the Grand Canal and buried underneath it;
- Concrete wet well, influent piping and a sluice gate;
- A new 66-inch sewer to connect VAPP to the new diversion structure;
- Fencing with blinds and vegetation for screening the VAPP building;
- Parking – a total of eight parking spaces will be provided at 128 Hurricane Street to allow for employee, delivery/visitor, and public parking, including the replacement of coastal parking,; and
- Landscaping, public art and open space at 128 Hurricane Street.

Project Schedule

Construction is anticipated to begin in March 2018 and last approximately two years. To minimize impacts on the surrounding community, streamline construction activities, and minimize overall Project cost, the City is planning to schedule construction of the VAPP immediately after completion of the Venice Dual Force Main (VDFM), which is planned to start construction in winter 2016 and end in winter 2019.

Required Approvals

Table ES-1, Required Permits for Venice Auxiliary Pumping Plant Project, lists the anticipated permits required for the Proposed Project.

Comments Received on the Notice of Preparation

In accordance with Section 15082 of the State CEQA Guidelines, LABOE prepared a Notice of Preparation/Initial Study (NOP/IS) for the Proposed Project on November 12, 2015. The NOP was circulated for 30 days. The comment period ended on December 18, 2015.

Table ES-1. Required Permits for Venice Auxiliary Pumping Plant Project

Agency	Permit/Requirement	Issue
Local		
City of Los Angeles Department of Public Works	Local Coastal Development Permit	Coastal access, construction within coastal zone, habitat disturbance, parking and traffic during construction
City of Los Angeles	Specific Plan Project Permit	Compliance with the Venice

Agency	Permit/Requirement	Issue
Planning Department	Compliance	Coastal Specific Plan. Also consistency with the Venice Local Coastal Program Land Use Plan
City of Los Angeles Planning Department	Public Benefits Project Permit	Section 14 of the Los Angeles Municipal Code. Public Benefit permit with Alternative Compliance for Public Facilities and Park/Recreation uses
City of Los Angeles Planning Department	Los Angeles Municipal Code Adjustment for Yards	Relief for encroachment more than 6 feet into the rear yard
City of Los Angeles Planning Department	Conditional Use Permit for Parking	Relief for encroachment more than 6 feet into the rear yard
Los Angeles County Department of Public Works/Department of Beaches and Harbors	Encroachment permit	Access and use of parcel for Laydown Area 2
City of Culver City, Planning Department	Temporary Use Permit	Temporary stockpile of soil (up to 7,700 cubic yards) for Laydown Area 3
Regional		
Los Angeles Regional Water Quality Control Board (RWQCB)	National Pollutant Discharge Elimination System (NPDES) Construction Stormwater Pollution Prevention Plan permit	Water quality and placement of discharges associated with dewatering activities; no permit required for discharges to sewer (general permit saves time with RWQCB)
RWQCB	401C section certification	State water quality certification prior to an issuance of U.S. Army Corps of Engineers (USACE) nationwide permit
South Coast Air Quality Management District	Permit to construct and operate	Air quality, additional portable generator(s), and any modifications to odor dispersion stack
State		
California Coastal Commission	State Coastal Development Permit	Coastal access, construction within coastal zone, habitat disturbance, parking and traffic during construction

Agency	Permit/Requirement	Issue
California Department of Conservation, Division of Oil, Gas, and Geothermal Resources	A construction notification form should be submitted to the division prior to any activity	Project is within boundaries of the Playa del Rey oil field, which contains numerous plugged and abandoned oil wells
State of California Department of Health Services	Project review for compliance with Title 22, Section 64630 (conducted through County Environmental Services Division)	Separation of water and sewer mains
California Office of Historic Preservation	Consultation	Historic status of Grand Canal
Federal		
USACE	Section 10 permit	Pipeline construction under navigable waters
USACE	Section 404	Could fall under Nationwide Permit NWP 12, Utility Line Activities, and require Pre-Construction Notification (PCN)
National Marine Fisheries Service	Consultation notification	Impacts on aquatic and marine life
U.S. Fish and Wildlife Service	Notification through Section 10 process	Impacts on habitat (i.e., least tern)

The NOP was also published in the *Los Angeles Times* and *The Argonaut* and made available on the LABOE website. Over 1,300 copies of this notice were circulated to members of the public, local and state agencies, and other interested parties to solicit comments on the Proposed Project. A total of 19 comment letters were received from agencies, tribes, interested organizations and the public. In addition, two scoping meetings were held on December 3rd and December 8th, 2015 within the local community.

Public comments submitted during the scoping period expressed concerns regarding the following issues (not listed in any particular order):

- Project Need
- Alternatives
- Air Quality
- Biological Resources
- Cultural Resources
- Hydrology and Water Quality
- Noise and Vibration
- Traffic

The public comment letters are included in Appendix A (Notice of Preparation/Initial Study) of this EIR.

Issues Raised

A summary of comments received and issues raised during the scoping meeting period is provided in Table ES-2, VAPP Comments Received on Notice of Preparation/Initial Study. This table includes issues identified and discussed in comment letters and orally at public meetings, and identifies the location in which the issues area addressed in the Draft EIR, as applicable.

Table ES-2. VAPP Comments Received on Notice of Preparation/Initial Study

Number	Commenter	Agency/Interested Party	Date of Correspondence	Summary of Issues	Section of Environmental Impact Report Where Issue Is Addressed
Federal Agencies					
1	Jessica Vargas, Regulatory Project Manager	Department of the Army Los Angeles District, U.S. Army Corps of Engineers	December 9, 2015	• As work on this project could fall within the Grand Canal, this activity may require a U.S. Army Corps of Engineers permit.	Sections 3.3 (Biological Resources) and 3.7 (Hydrology and Water Quality)
State Agencies					
2	Dianna Watson, IGR/CEQA Branch Chief	California Department of Transportation	December 8, 2015	• A traffic study should be prepared. Please refer the project's traffic consultant to Caltrans' traffic study guide Website: http://www.dot.ca.gov/hq/tpp/offices/ocp/igr ceqa files/tisguide.pdf • A Congestion Management Plan should be included. If the County's Congestion Monitoring Plan (CMP) is used to evaluate the impacts, the consultant should demonstrate that the methods and procedures used are compatible and are in compliance with TIS guidelines. The Highway Capacity Manual method must be used in analyzing traffic impacts on freeway off-ramps including queuing along ramps and ramp intersections. The ICU method recommended in CMP is not acceptable for evaluating the impacts on State transportation system. The DEIR should consider all State transportation facilities located within zone recommended by TIS guidelines. All exceptions or variations should be approved by Caltrans. • Future conditions, including project and project plus cumulative traffic generated up to General Plan build out year should be included. • Discussion of mitigation measures as appropriate, including sharing of mitigation costs.	Section 3.10 (Transportation/Traffic)
3	Loni Adams, Marine Environmental Scientist	California Department of Fish and Wildlife	December 9, 2015	• The impacts to the canal appear to be temporary.	Sections 3.3 (Biological Resources) and 3.7 (Hydrology and Water Quality)
Native American Groups					
4	Andrew Salas, Chairman	Gabrieleno Indians Gabrieleño Band of Mission Indians – Kizh Nation	November 30, 2015	• Project is located in a highly sensitive area; Believes there is a high likelihood for discovering human remains given the proximity to the nearby Play Vista site and requests that one of their Native American monitors be used during ground disturbance activities to protect any cultural resources that may be found during construction.	Section 3.4 (Cultural Resources)
5	John Tommy Rosas		November 24, 2015	• No comment.	No response required.
6	Caitlin B. Gulley Tribal Historic and Cultural Preservation Officer	Fernandeño Tataviam Band of Mission Indians	December 1, 2015	• Indicates that the Proposed Project is outside of both boundaries of the traditional Tataviam territory map provided to the City of Los Angeles and therefore, does not wish to consult on the Proposed Project.	No response required.
Local Agencies					
7	Gail Farber, Director of Public Works	County of Los Angeles Department of Public Works and Department of Beaches and Harbors	December 17, 2015	• Would like the opportunity to review the traffic impact analysis and the DEIR prior to the release of the document to the public for potential impacts to County intersections and roadways in the area including impacts during the construction phase. • Any construction traffic control measures or detours that will impact traffic in the unincorporated County community of Marina del Rey would need to be evaluated and discussed in the environmental document. • It should be noted in the DEIR that a construction permit, including the preparation of a traffic control plan, will be required for installation of any traffic control, temporary lane closures, or lane transitions placed by the	Section 3.10 (Transportation/Traffic) and Chapter 2 (Project Description)

Number	Commenter	Agency/Interested Party	Date of Correspondence	Summary of Issues	Section of Environmental Impact Report Where Issue Is Addressed
				project in the County's jurisdiction. • The DEIR should also disclose a proposed construction schedule that has been coordinated with the Departments of Public Works and Beaches and Harbors for potential conflicts with other County projects and special events in the Marina. • The EIR shall include discussions regarding the possible use of Lot F, which is owned by the County of Los Angeles, for construction staging purposes. These discussions shall address how the staging needs for the VAPP project correlate to the staging needs of the City's Venice Dual Force Main project that will also be taking place in Lot F for an extended period of time. The EIR shall also indicate that a right-of-entry permit from the Department of Beaches and Harbors will be needed for the use of any County-owned lots.	
Interested Parties/Public					
Public Scoping Meeting – December 3, 2015					
8	Steve Bradbury	Public	Public Testimony	• Concerned about duration of project given that the recently completed Venice Manifold Project (VMP) took longer than expected. • No mitigation for truck noise during the VMP. • Poor communication with residents on the VMP and the site and area was dirty with lots of dust generated. • Parking was a problem during the VMP. • Concerned about the closure of Hurricane Street and reduced property values due to presence of the project. This will also eliminate his views. • Additional explanation is needed regarding why Hurricane Street needs to be closed off. • The project has been in the planning stage for some time, but this has not been communicated to the residents.	Chapter 2 (Project Description) and Sections 3.2 (Air Quality), 3.9 (Noise & Vibration), and 3.10 (Transportation/Traffic)
Public Scoping Meeting – December 8, 2015					
9	Ms. Morrill-Borassi	Public	Public Testimony	• Would like to understand why this project was not included in the VMP. • Concerned that proposed open space amenities will not be implemented, due to resident opposition. • Would like to know if a car wash will be provided due to all of the construction activities. • Would like to know what mitigation measures are proposed for noise. • Concerned about parking.	Chapter 2 (Project Description) and Sections 3.2 (Air Quality) and 3.9 (Noise and Vibration), and 3.10 (Transportation/Traffic)
10	Bob Debiase	Public	Public Testimony	• Concerned about noise and vibration generated from equipment. • Would like to understand the need for the project.	Chapter (Project Description) and Section 3.9 (Noise and Vibration)
11	Mike Borassi	Public	Public Testimony	• Would like to know if the project is necessary or preventive.	Chapter 2 (Project Description)
12	Walter Lamb	Public	November 20, 2015	• The EIR should analyze impacts to natural resources, including to native birds and other wildlife.	Section 3.3 (Biological Resources)
13	Arthur Pugsley, Senior Attorney	Los Angeles Waterkeeper	December 7, 2015	• EIR should provide an expanded discussion of why the Project is needed and its role in the broader LABOE efforts to manage its sewage and stormwater systems. • Proposes the inclusion of an additional project objective in the Environmental Impact Report to address water recycling in both the short- and medium-term. • Proposes the inclusion of a an alternative entailing pumping to a destination for treatment and use as recycled water, and/ or an alternative to ultimate ocean discharge of the water pumped through the Venice pumps. • The EIR should explain efforts of LABOE to coordinate with other City departments to ensure project design promotes current City administration's sustainability goals. • Include a discussion of construction and permanent impacts to the Grand Canal, other nearby environmentally sensitive habitat areas, and rare species habitat. • The EIR should also detail the Low Impact Design methods being taken to ensure infiltration of stormwater from	Chapter 2 (Project Description) and Sections 3.3 (Biological Resources), 3.7 (Hydrology and Water Quality), 3.8 (Land Use and Planning), 3.10 (Transportation/Traffic), Chapter 4 (Alternatives)

Number	Commenter	Agency/Interested Party	Date of Correspondence	Summary of Issues	Section of Environmental Impact Report Where Issue Is Addressed
				the project site itself. • The EIR should discuss cumulative impacts related to the loss of parking and direct and indirect impacts on coastal access from reduced parking supply.	
14	Daniel P Whalen and Sharon McQueen	McQueen-Whalen Revocable Trust	November 25, 2015	• The Proposed Project is incompatible with the current residential zoning, is located adjacent to Environmentally Sensitive Habitat Area, and should be located to "U" zoned location and should not be allowed to proceed. • Vacation of Hurricane Street should not be allowed since it would restrict coastal access. • Indicates that 11 environmental resource areas and mandatory findings of significance were identified to result in potentially significant impacts, but no mitigation measures were identified. • Indicates that the project is not compatible with the current zoning and surrounding community, it degrades the environmental habitat, it diminishes an historical resource, it violates California Coastal Commission standards for coastal access, and will adversely affect the quality of life (views, traffic, light, odor, noise, etc.) for the surrounding residents.	Chapter 2 (Project Description) and Sections 3.8 (Land Use and Planning), 3.10 (Transportation/Traffic), 3.1 (Aesthetics), 3.2 (Air Quality), and 3.9 (Noise and Vibration)
15	Barbara Brunasso	Public	November 17, 2015	• Questions the need for the project. • Requests further clarification on capacity needs and how the project relates to the One Water LA 2040 Plan (Plan) and other conservation plans for the greater Los Angeles Area. Would like to know if cost for project would be covered through the Plan. • Would like to know if a study has been undertaken regarding the cost and efficiency of refurbishing and limited expansion of current Venice Pumping Plant to provide additional reliability and supplement capacity. • Requests information on the economic gains to the community, including local construction workers, and others. • Indicates that cultural events will be sacrificed due to the cost of construction of the project and requests a dollar amount for this. • Requests information and/or clarification on where and when increased congestion will occur and to avoid peak periods and how long project will take to complete. • Concerned about the potential for odors during construction and requests that these activities be undertaken during summer. • Request explanation of why vacation of Hurricane Street is needed and the length of the road needed.	Chapter 2 (Project Description), Sections 3.2 (Air Quality), 3.8 (Land Use and Planning), 3.10 (Transportation/Traffic), and Chapter 4 (Alternatives)
16	Clare Bronowski	Public	November 30, 2015	• Requests that the LABOE undertake careful construction and restoration mitigation measures to ensure that the project does not impact the sensitive canal and canal bank area. • Concerned that LABOE does not understand the ecologically sensitive residential neighborhood and cites the recent street and drainage projects undertaken that did not consider aesthetic and ecological issues. • Requests that LABOE review the Grand Canal Master Plan to understand what is required and/or should be included in the restoration efforts associated with the project. • Indicates that the project site, including Laydown Areas are zoned • RW2-1 and as such, industrial uses are not permitted. Therefore, LABOE must undertake a zone change with the City's Planning Department. As part of that process, conditions and measures to ensure compatibility with existing neighborhood character need to be included. • Plans and visual representation of the proposed plant need to be provided, since these were not included in the Notice of Preparation. • Concerned about the existing visual aesthetics of the Venice Pumping Plant Station and notes that landscaping including planting in the planters is not maintained. • Indicates that a process is needed to ensure that the visual impact of the new project, as well as landscaping and screening of the existing plant, is mitigated with good design and neighborhood compatible features. • Indicates that the existing Venice Pumping Plant creates odors and additional measures need to be taken to control this issue. • Indicates that vacation of Hurricane Street will remove scarce neighborhood street parking and must be	Chapter 2 (Project Description) and Sections 3.1 (Aesthetics), 3.2 (Air Quality), 3.3 (Biological Resources), 3.8 (Land Use & Planning), and 3.10 (Transportation/Traffic)

Number	Commenter	Agency/Interested Party	Date of Correspondence	Summary of Issues	Section of Environmental Impact Report Where Issue Is Addressed
				mitigated. • Request mitigation to address increased pedestrian access along walkway at the existing Venice Pumping Plant. • Request that loss of pedestrian and vehicular access on Hurricane include improved pedestrian access from Washington as well as improvements such as fencing and native vegetation in the canal area.	
17	Gary Wells	Public	November 17, 2015	a) Indicates that he is building a single-family home on northern parcel of the area identified in NOP as Laydown Area 2 and is processing permits through the California Coastal Commission. He is not granting access to or use of the property to LABOE.	Chapter 2 (Project Description).
18	Michael Rosenfield	Public	November 16, 2015	b) Would like to know what is planned for Laydown Area 2.	Chapter 2 (Project Description)
19	William Boyd	Public	November 18, 2015	c) Will fuel oil storage be included or will they be powered by natural gas? Concerned about cumulative impacts from related projects, loss of pedestrian access.	Chapter 3 (Project Description) and Sections 3.10 (Transportation/Traffic) and 3.6 (Cumulative Impacts)

Issues to Be Resolved

Issues to be resolved by the Los Angeles Department of Public Works, Bureau of Engineering (LABOE), include the following:

- Determine whether the EIR adequately describes the environmental impacts of the Proposed Project;
- Determine whether the recommended mitigation measures should be adopted or modified;
- Determine whether additional mitigation measures need to be applied to the Proposed Project; and
- Consider the information contained in the administrative record, created during the environmental review process, and determine whether to approve the Proposed Project

Summary of Environmental Impacts

Impacts Determined to Require No Further Consideration in This EIR

As discussed in Appendix A and Chapter 5, Other Environmental Considerations of this Draft EIR, the Proposed Project was determined to have no impact or less than significant impacts with regard to the following impact thresholds, which are, therefore, not analyzed in this Draft EIR:

- Agriculture and Forestry Resources
- Hazards and Hazardous Materials
- Mineral Resources
- Population and Housing
- Public Services
- Recreation

Chapter 5 discusses impacts to these resource areas.

Impacts Determined to Be Less than Significant

The analysis contained in the Draft EIR determined that the Proposed Project would result in less than significant or less than significant impacts after mitigation is implemented for the following resources:

- Aesthetics
- Air Quality
- Biological Resources
- Cultural Resources
- Geology and Soils

- Greenhouse Gas Emissions
- Hydrology and Water Quality & Service Systems
- Land Use and Planning (operation only, for secondary noise and vibration impacts)
- Noise and Vibration (operation only, for noise and vibration)
- Transportation/Traffic
- Energy (except cumulative)

These impacts are evaluated in detail in Chapter 3 of this Draft EIR and are summarized in Table ES-3 at the end of this Executive Summary.

Significant Unavoidable Impacts

Noise and vibration during construction, even with the application of mitigation measures would remain significant and unavoidable. In addition, secondary impacts on surrounding land uses related to noise and vibration would also be significant and unavoidable, during construction only. These impacts would occur only during the duration of construction, which is anticipated to last 24 months. The Proposed Project would result in significant unavoidable impacts related to tsunami and sea level rise during operation.

Cumulative Impacts

Cumulative noise and vibration impacts during construction would be significant and unavoidable, even with the application of mitigation measures. In addition, cumulative impacts related to energy are considered potentially significant. All other environmental resource areas analyzed in the document have either no cumulative impacts, or the cumulative impacts are less than significant.

Significant Irreversible Environmental Changes that Would Be Caused by the Proposed Project Should It Be Implemented

Implementation of the Proposed Project would commit nonrenewable (e.g., petroleum) or slowly renewable (e.g., timber) resources during Project construction and operation. In order to construct the Proposed Project, machinery, equipment, materials (e.g., lumber, sand, gravel) and workers would be required, representing an irreversible commitment of some of these resources. Similarly, during operation, some of these resources (e.g., energy, electricity) would again be needed, representing a long-term commitment and permanent investment. The consumption and use of some of these resources would limit their availability for future generations. In addition, construction of the Proposed Project would also irreversibly change existing views to and from the Grand Canal and Ballona Lagoon for both visitors and residents. However, assuming that these commitments would occur in accordance with the adopted goals, policies, and implementation measures of the City of Los Angeles General Plan, Venice Local Coastal Program, Venice Community Plan, and Venice Local Coastal Specific Plan, as a matter of public policy, such commitments would be acceptable. The Proposed Project would also provide important redundancy in pumping capacity for system reliability and safety and ensure that the VPP can adequately perform during wet weather flows. Therefore, the significant irreversible changes have been deemed acceptable in light of the Proposed Project's overall benefits.

Growth-Inducing Impacts

The overall objective of the Proposed Project is to reduce the risk of sewage spills by providing redundancy and system reliability for the existing VPP wastewater collection system. The Proposed Project would also allow the system to handle future risks related to climate change, including increased storm intensities, which have the potential to result in extreme wet weather flows that would be beyond the capacity of the existing VPP. In addition, the Proposed Project is not intended to facilitate growth but instead address existing deficiencies in the system that have been identified and planned for through the City of Los Angeles' normal infrastructure assessment practices. Therefore, the Proposed Project is not considered growth inducing.

Alternatives and the Environmentally Superior Alternative

As noted in Chapter 4 (Comparison of Alternatives) of this EIR, on December 1, 2015 and on June 11, 2016, LABOE and its design team conducted Project Development Team meetings to develop, evaluate, and screen Project alternatives. This was undertaken in order comply with CEQA and to develop a reasonable range of alternatives for consideration in the EIR. Including the mandatory No Project/No Build alternative, a total of six build alternatives were developed and included the following:

- No Project/No Build
- Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade
- Use of Temporary At-grade Pumps with External Piping at Venice Pumping Plant and/or Along Hurricane Street
- Build new Plant on Proposed Site and Decommission and Demolish existing Venice Pumping Plant
- Expand Existing Venice Pumping Plant and Install Pumps and Piping Below-grade
- Construct VAPP Underground at Proposed Project Site Location with Control Room Located Off-site
- Construct Auxiliary Pumping Plant at Alternate Location along Coastal Interceptor Sewer

An analysis of these alternatives determined that the No Project/No Build alternative, Proposed Project, and Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade alternative should be evaluated in the EIR, while the remaining alternatives were identified as infeasible and rejected from further evaluation. The analysis then evaluated and compared the No Project/No Build and Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade alternatives and determined that the No Project/No Build was the Environmentally Superior Alternative. Pursuant to CEQA regulations (see CEQA Guidelines Section 15126.6(e)(2)), when the No Project Alternative is identified as the environmentally superior alternative, the EIR shall also identify an environmentally superior alternative from among the other alternatives. To determine which of the other alternatives would be environmentally superior, the analysis focused on those Proposed Project

impacts identified as significant and unavoidable. Based upon the analysis contained in Chapter 4, Comparison of Alternatives of this EIR, the Proposed Project was determined to be the Environmentally Superior Alternative.

Summary of Impacts and Mitigation Measures

Table ES-3 contains a summary of impacts by environmental resource area, the significance determination before mitigation, required mitigation measures (if any), and any remaining impacts after mitigation is applied.

Table ES-3. Summary of Environmental Impacts

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Aesthetics			
AES –1-7. Aesthetics. Construction would result in temporary visual impacts due to the presence of construction equipment, staging areas, exposed excavation areas, associated construction fencing, and temporary cofferdam. Dust from excavation and construction equipment would also be generated. Vegetation on the west bank would be removed. However, no important visual features would be removed and vegetation on the west bank of the canal would be replaced (see Mitigation Measure MM-BIO-3 below). Once operational, the major visible built elements would include an electrical building up to 32 feet in height and security walls. Other project elements would be minimally visible. No natural open space would be graded or developed. The Proposed Project would provide additional green and open space and access to the Grand	Less than Significant	**MM AES-1: Construction Staging/Stockpiled Materials and Equipment.** LABOE or its construction contractor shall be the responsible party for providing temporary construction fencing along the periphery of active construction areas to screen as much of the construction activity as possible from view at the street level. To minimize views of stockpiled materials and idle construction equipment in staging areas and reduce visual clutter and disorder, Project construction staging areas shall be enclosed or screened from view at the street level with appropriate screening materials. The contractor shall provide daily visual inspections to ensure that areas immediately surrounding the construction staging areas are free from construction-related clutter and graffiti and maintained in a clean and orderly manner throughout the construction period. Graffiti shall be painted over, masked out, or cleaned off within 24 hours after notification by the Project inspector. **MM AES-2: Nighttime Construction Activities.** Should emergency construction activities occur at night, LABOE or its construction contractor shall ensure that lighting will be directed away from surrounding sensitive land uses, particularly residences, and toward the specific location intended for illumination. Lighting associated with construction activities or for security purposes shall be shielded to minimize glare and spill light around sensitive land uses in the surrounding area. **MM AES-3: Final Design**. LABOE shall ensure that all Proposed Project structures will be designed to minimize their visual presence. Where site and design allow, the Project elements shall incorporate design and location features that minimize the size of the structures and provide setbacks from adjoining street frontages, screening, and/or architectural treatments that are appropriate to the design setting where visible from the public	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Canal. Project elements would not substantially alter the visual quality and/or character of the site.		right-of-way at street level. Where necessary, structures shall be designed and built to the satisfaction of the City Engineer/City Architect and in compliance with all applicable design guidelines, policies, and development standards, as discussed Section 3.1.1, *Regulatory Setting*. **MM-BMP-AES-1: Resident Vouchers for Window Washing and Car Washes during Construction.** LABOE or its construction contractor will implement best available control measures, as required by SCAQMD Rule 403 regarding fugitive dust, and other relevant regulations related to controlling dust from construction activities. However, to minimize any aesthetic impact construction dust may have on nearby neighboring cars and resident windows, the Public Affairs Office of the Department of Public Works shall provide vouchers to immediately adjacent residents for window washing and car washes, as appropriate.	
VIEWS-1-4. Obstruction of Views. Construction and operation of the Proposed Project would not create permanent blockage of visual resources or substantially diminish the nature and quality of recognized or valued private and public views. Temporary construction activities could diminish visual quality or character and, thus, valued views of the immediate area. Operation of the Proposed Project would not substantially diminish or alter valued views throughout the Project area.	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
SHADE-1. *Shading*. Construction and operation of the Proposed Project would not cast shadows that would affect shade-sensitive viewers.	Less than Significant	No mitigation measures are required.	Less than Significant
LIGHT-1 & LIGHT 2. *Nighttime Illumination*. Nighttime lighting at the construction site could be required, which could result in a temporary shift in ambient illumination levels as a result of project sources and spillover of light from project lighting. Operation of the Proposed Project would not introduce substantial illumination, relative to existing conditions and new lighting would be directed away from sensitive receptors.	Less than Significant	Implement MMAES-2, as noted above.	Less than Significant
Cumulative Impacts. Neither the related projects (see Chapter 1, Introduction [Table 1-1, Related Projects List] of this EIR) nor the Proposed Project are expected to adversely affect visual character and quality, nor result in effects that are potentially cumulatively significant.	Less than Significant	No mitigation measures are required.	Less than Significant
Air Quality			

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
AQ-1. Conflict with air quality plan. The Proposed Project would comply with Consistency Criterion 1 and 2. The Proposed Project would not conflict with or obstruct implementation of the Air Quality Management Plan (AQMP).	Less than Significant	No mitigation measures are required.	Less than Significant
AQ-2. Violate air quality standard or contribute to air quality violation. The Proposed Project would contribute to regional air pollutant emissions during short-term construction. As shown in Table 3.2-6, maximum daily Project-related criteria pollutant emissions would not exceed SCAQMD construction-period regional thresholds for any pollutant. Consequently, the impact of construction-related emissions on regional air quality would not violate any air quality standard or contribute substantially to an existing or projected air quality violation. The impact of construction-related emissions on local air quality would not violate any air quality standard or contribute substantially to an existing or projected air	Less than Significant	**MM AQ-1:** All off-road diesel-powered construction equipment greater than 50 horsepower will meet Tier 3 emission standards. All construction equipment will be outfitted with ARB best available control technology devices. Any emissions-control device used by the contractor will achieve emissions reductions that are no less than what could be achieved by a Level 3 diesel emissions control strategy for a similarly sized engine as defined by ARB regulations. A copy of each unit's certified tier specification, best available control technology documentation, and ARB or SCAQMD operating permit will be provided at the time of mobilization of each applicable unit of equipment.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
quality violation. With regards to localized emissions, as seen in Table 3.2-7, the Proposed Project would exceed the localized significance threshold (LST) for PM10 emissions.			
AQ-3. Result in cumulatively considerable net increase of criteria pollutant for which the region is non-attainment. Construction-period emissions would be short term in nature and occur over 24 months, with no long-term construction-related emissions	Less than Significant	No mitigation measures are required.	Less than Significant
AQ-4. Expose sensitive receptors to substantial pollutant concentrations. As discussed above, mitigation has been incorporated to ensure that the Proposed Project would not result in an exceedance of LST such that significant impacts on sensitive receptors would result. The TAC exposure period for sensitive receptors would be substantially less than the 30-year exposure assumed for residential cancer risks in South Coast Air Quality Management District (SCAQMD) guidance (SCAQMD 2015).	Less than Significant	Implement MM AQ-1, as noted above.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
AQ-5. Create objectionable odors affecting a substantial number of people. During the construction period, site preparation and excavation could involve the short-term generation of odors in the vicinity of the Project Site, mostly related to diesel exhaust from construction equipment and excavation within the Grand Canal associated with the coffer dam and stockpiling of this soil within Laydown Areas 1 and 3. No operational odors would occur.	Less than Significant	No mitigation measures are required.	Less than Significant
Cumulative Impacts. Given that each of the related projects would be required to mitigate any of its impacts and comply with Rule 403, impacts would not be cumulatively considerable and would not conflict with or obstruct implementation of the SCAQMD AQMP. The Proposed Project in combination with related projects are not expected to result cumulatively considerable increase in pollutant emissions and would not conflict with or obstruct implementation of the SCAQMD AQMP.	No impact	No mitigation measures are required.	No impact

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Biological Resources			
BIO-1. Special-Status Plants. Wooly seablight (*Suaeda taxifolia)* may be affected by construction along the canal banks. Other special-status species were observed in the study area but are currently absent within the disturbance footprint.	Potentially Significant	**MM BIO-1:** To confirm the presence/absence of special-status plant species within the disturbance footprint, a special-status plant survey shall be completed prior to construction. The focused survey shall be conducted by a qualified biologist during the appropriate blooming period, or when the plant is readily identifiable, prior to the start of construction activities. If any sensitive non-listed plant species is found, then the individuals will be clearly identified and avoidance measures shall be utilized to the extent practical.	Less than Significant
BIO-1. Special-Status Wildlife. The following species, which have a low to moderate potential to occur in the project area, could be affected during construction, if present: El Segundo blue butterfly, Belding's savannah sparrow, Light-footed clapper rail, and California Least tern.	Potentially Significant	Implement MM BIO-1, as noted above and: **MM BIO-2:** A qualified biologist shall monitor all vegetation removal and ground-disturbing activities, such as staging and grading, for the duration of the Project to ensure that practicable measures are being employed to avoid incidental disturbance of habitat outside the Project footprint and to survey for sensitive wildlife species. When vegetation removal and ground-disturbing activities are not occurring, as-needed monitoring at the Project Site shall occur. Monitoring logs, as appropriate depending on Project activities, shall be maintained for the duration of construction activities. **MM BIO-3:** The disturbance footprint within the Grand Canal shall be restored by seeding and/or container plant installation following construction. Restoration shall be performed in coordination with CCC, USACE, and RWQCB as required during the permitting phase. **MM BIO-4:** Work crews shall properly dispose of all garbage in covered containers to avoid attracting predators (such as crows and ravens) that could contribute indirectly to depredation of California least tern eggs and chicks in the nearby nesting colony. **MM BIO-5:** Water quality shall be monitored by the qualified biologist or a water quality specialist to ensure that no substantial increases in turbidity occur during construction. The contractor shall ensure compliance with RWQCB Section 401	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
		Water Quality Certification, USACE Section 404 authorization, applicable water-quality related Best Management Practices, and the Project Storm Water Pollution Prevention Plan.	
BIO-1. Nesting Birds. Construction of the Proposed Project could affect nesting birds protected under the Migratory Bird Treaty Act and California Fish and Game Code Sections.	Potentially Significant	Implement MM BIO-2**,** MM BIO-4, and MM BIO-5, as noted above and: **MM BIO-6:** If construction commences during the bird breeding season (February 15 through August 31), a preconstruction survey for nesting birds shall occur within three days prior to construction activities by an experienced avian biologist. The survey shall occur within all suitable nesting habitat within the Project impact area and a 500-foot buffer. If nesting birds are found, an avoidance area shall be established in consultation with the resource agencies as appropriate by a qualified biologist around the nest until a qualified avian biologist has determined that young have fledged or nesting activities have ceased. The Project Site shall be re-surveyed if there is a lapse in construction activities for more than seven days during the bird breeding season.	Less than Significant
BIO-1. Raptor Foraging. Construction of the Proposed Project is not expected to adversely affect raptor foraging habitat.	Less than Significant	Implement MM BIO-2**,** MM BIO-4, MM BIO-5, and MM BIO-6, as noted above.	Less than Significant
BIO-1. Essential Fish Habitat. No designated Essential Fish Habitat is present within the study area.	No Impact	No mitigation measures are required.	No Impact
BIO-2. Vegetation Communities. The Project would result in a total of 0.37 acre of short-term temporary direct impacts to vegetation communities (excluding developed areas). These impacts would occur during the construction phase only	Potentially Significant	Implement MM BIO-2 and MM BIO-3**,** as noted above and: **MM BIO-7:** Construction limits shall be demarcated using environmentally sensitive area silt fencing, which shall be installed under the supervision of a qualified biologist prior to the commencement of work. Construction personnel shall strictly limit their activities, vehicles, equipment, and construction materials to the Project footprint, including designated staging areas, and routes of travel. The construction	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
and no operational impacts would occur.		areas shall consist of the minimal area necessary to complete the Proposed Project. The fencing shall remain in place until the completion of all construction activities. **MM BIO-9:** The temporary work area within Grand Canal within mudflat/open water shall be returned to pre-construction grade and contours following construction.	
BIO-2. Environmentally Sensitive Habitat Areas (ESHAs). The Grand Canal and Ballona Lagoon are classified as an ESHA. Construction of the Proposed Project could result in direct and indirect temporary impacts on this designated ESHA due to the loss of individuals or reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community.	Potentially Significant	Implement MM-BIO-7, as noted above, and: **MM BIO-8:** Existing functions and values in ESHA shall be protected, enhanced, and restored as necessary to previous undisturbed conditions in accordance with applicable USACE, RWQCB, CCC, or City of Los Angeles requirements.	Less than Significant
BIO-3 Interfere with Species Behaviors. Increased light exposure from temporary construction lighting and increased sedimentation could diminish long-term species survival.	Potentially Significant	Implement MM-BIO-1, MM-BIO-2, MM-BIO-4, MM-BIO-5, MM-BIO-6, and MM-BIO-7, as noted above.	
BIO-4. Aquatic Resources: The Project occurs within the jurisdiction of several agencies including, but not limited to, U.S. Army Corps of Engineers (USACE), Regional Water Quality Control Board (RWQCB), and California	Potentially Significant	Implement Mitigation Measures BIO-3, BIO-5, and MM BIO-9, as noted above.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Coastal Commission (CCC) and would result in temporary direct and indirect impacts to aquatic resources, including an existing wetland habitat. These impacts are significant without mitigation. Applicable permits from resource agencies would be obtained during the permitting phase prior to construction and all permit conditions and avoidance and minimization measures will be implemented.			
BIO-5. Wildlife Corridors: Because the study area does not contain any identified wildlife corridors, it would not result in interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species.	Less than Significant	No mitigation measures are required.	Less than Significant
Cumulative Impacts. Neither the related projects (see Chapter 1, Introduction [Table 1-1, Related Projects List] of this EIR) nor the Proposed Project are expected to result in substantial adverse effects on biological resources, nor result in effects that are potentially cumulatively significant, after implementation of proposed	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
mitigation measures.			
Cultural Resources			
CUL-1. Archaeological Resources. The potential for encountering archaeological resources during construction is low. However, in the unlikely event that archaeological resources are present on the Project Site, construction activities could disturb, damage, or degrade those resources.	Potentially Significant	**MM CUL-1: Unanticipated Discovery.** In the unlikely event that any prehistoric artifact of historic period materials or bone, shell, or nonnative stone is encountered during construction, work shall be immediately stopped, the area secured, and work relocated to another area until the found materials can be assessed by a qualified archaeologist. Examples of such cultural materials might include historical trash pits containing bottles and/or ceramics; or structural remains or concentrations of grinding stone tools such as mortars, bowls, pestles, and manos; chipped stone tools such as projectile points or choppers; and flakes of stone not consistent with the immediate geology such as obsidian or fused shale. The contractor shall stop construction within 30 feet of the exposure of these finds until a qualified archaeologist can be retained to evaluate the find (see 36 CFR 800.11.1 and 14 CCR 15064.5(f)). If the resources are found to be significant, they shall be avoided or impacts shall be mitigated consistent with Section 106 or State Historic Preservation Officer Guidelines.	Less than Significant
CUL-2 & CUL-4. Tribal Cultural Resources (TCRs). There are no known TCRs within the Project footprint; therefore, no construction or operational impacts are anticipated.	Less than Significant	No mitigation measures are required.	Less than Significant
CUL-3. Historical Resources. Construction would require that a temporary cofferdam be placed in the Grand Canal, which is the only historical resource in the study area. The cofferdam would be removed pending completion of construction activities and	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
the diversion structure installed under the Grand Canal and would not protrude into the water surface and would be entirely buried. No operational impacts would occur to the Grand Canal.			
Cumulative Impacts. Neither the related projects (see Chapter 1, Introduction [Table 1-1, Related Projects List] of this EIR) nor the Proposed Project are expected to adversely affect cultural resources, nor result in effects that are potentially cumulatively significant.	Less than Significant	No mitigation measures are required.	Less than Significant
Geology and Soils			
GEO-1. Seismic Hazards. During construction and operation, the Project Site could be subject to significant seismic ground shaking from regional faults; however the VAPP would be designed in conformance with the City of Los Angeles Building Code, which would reduce potential ground shaking hazards. Due to presence of uncertified fill soils, seismically related ground failure, including liquefaction, could occur on the Project Site.	Potentially Significant	**MM GEO-1: Liquefaction Considerations.** Given the data presented in Section 3 of the *Geotechnical Engineering Report – Venice Auxiliary Pumping Plant*, December 14, 2015, and the results of the liquefaction calculations, potential liquefaction induced settlements on the order of 1.75 inches are estimated for the site. A potential liquefaction induced differential settlement of 1 inch is estimated between the proposed structures and the pipe header. These potential liquefaction induced settlements shall be considered and accounted for in the design of the Proposed Project. Mat foundations are recommended for support of the Project structures, with the understanding that the foundation would be susceptible to liquefaction-induced settlements. Mat foundations for the wetwell/valve structure and diversion structures shall be founded on jet-grouted columns constructed within the natural soils. The mat foundation for the electrical building shall be founded on compacted fill soil. Mat foundations shall be designed and constructed to bear at a depth of at least 24 inches below the	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
		lowest adjacent grade. Mat foundations can be designed for an allowable bearing capacity of 1,500 pounds per square foot (psf). A coefficient of vertical subgrade reaction, for a 1-foot-square loaded area, of 100 kips per cubic foot (kcf) may be used for design of the mats. Total static settlement of the proposed foundations, designed and constructed in accordance with the recommendations presented herein, shall not exceed 1 inch. Differential static settlement shall not exceed one-half of the total settlement. Resistance to lateral loads can be provided by friction at the base of the foundation and passive earth pressure. A coefficient of friction of 0.35 may be assumed with dead-load forces. An allowable passive lateral earth pressure of 250 psf per foot of depth up to a maximum of 2,500 psf may be used for sides of the foundation poured against undisturbed natural soil or properly compacted fill. The allowable passive pressure may be increased by 33% of lateral loading due to wind or seismic forces.	
GEO-2. Unstable Soils. The Project Site is not located within an earthquake-induced landslide hazard zone and it does not contain lateral spreading, subsidence, or collapse hazards. The Project Site is subject to liquefaction hazard.	Less than Significant	Implement MM GEO-1, as noted above.	Less than Significant
GEO-3. Expansive Soils. The Project Site is not located on expansive soils.	Less than Significant	No mitigation measures are required.	Less than Significant
HAZ-1.Release of Hazardous Materials. The parcel located at 128 Hurricane Street lies within the administrative boundaries of the Playa Del Rey Oil Field. One oil well 'McDonald 2' and the Project	Potentially Significant	**MM HAZ-1a: Soil and Soil Vapor Subsurface Investigation**. Prior to construction, a soil and soil vapor subsurface investigation shall be conducted by a qualified environmental consultant specializing in the identification and handling of hazardous materials. The subsurface investigation may include, but would not be limited to: d) A scope of work consisting of Pre-Field Activities, such as	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Site is located within a methane zone.		preparation of a Health and Safety Plan (HASP), determining and marking sampling/boring locations and obtaining utility clearance, and Field Activities, such as identifying appropriate sampling procedures, health and safety measures, chemical testing methods, and quality assurance/quality control (QA/QC) procedures in accordance with the ASTM Standard. e) Necessary permits for boring advancement. f) A Sampling and Analysis Plan (SAP) in accordance with the scope of work. g) Laboratory analyses conducted by a State-certified laboratory. h) Disposal process including transport by a State-certified hazardous material hauler to a State-certified disposal or recycling facility licensed to accept and treat hazardous waste. **MM HAZ-1b: Confirmation of Oil Well Abandonment**. Prior to construction, the applicant shall obtain confirmation via DOGGR of the proper abandonment of oil well 'McDonald 2'. If re-abandonment of McDonald 2 was not performed to current DOGGR requirements, the applicant shall seek the assistance of a qualified environmental consultant to abandon the oil well to current standards. **MM HAZ-2: Methane Encroachment**. If the analytical results of the subsurface investigation under Mitigation Measure HAZ-1a determine that methane encroachment has the potential to affect VAPP operational activities, the environmental consultant shall provide recommendations during construction of the proposed project to mitigate long term potential impacts.	
Cumulative Impacts. Neither the related projects (see Chapter 1, Introduction [Table 1-1, Related Projects List] of this EIR) nor the Proposed Project are	Less than Significant	See MM GEO-1 above. No other mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
expected to result in adverse effects related to geology and soils, nor result in effects that are potentially cumulatively significant, after implementation of mitigation measures.			
Greenhouse Gas Emissions			
GHG-1. Generation of GHGs: Construction of the Proposed Project would result in GHG emissions from fuel combustion associated with heavy-duty construction equipment, construction workers' vehicle trips, material deliveries, and trips by haul trucks. GHG emissions resulting from Project implementation would not exceed SCAQMD's 10,000-metric-ton threshold, and impacts would be less than significant.	Less than Significant	No mitigation measures are required.	Less than Significant
GHG-2. Potential for Conflict with GHG Reduction Plans: Implementation of the Proposed Project would not generate GHGs that would exceed existing conditions and the interim SCAQMD threshold or applicable plans.	Less than Significant	No mitigation measures are required.	Less than Significant
Cumulative impacts: GHGs and climate change are cumulatively considerable, even though the contribution	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
may be individually limited (SCAQMD 2008). SCAQMD methodology and thresholds are thus cumulative in nature. As discussed above, the Proposed Project would not exceed the threshold of significance. Therefore, the Proposed Project would not contribute to a cumulatively significant impact related to GHG emissions and climate change.			
Hydrology and Water Quality			
HYRDO-1. Water Quality. Construction activities, such as grading and excavation, could increase the potential for erosion and sediment transport via stormwater runoff (or wind) to the storm drain system and ultimately to the Grand Canal other nearby water bodies, adversely affecting water quality. The construction of a temporary cofferdam in the Grand Canal would require installation of sheeting that would disturb existing sediments in the Grand Canal, which could also impair water quality. Compliance with existing regulations and permit requirements would minimize potential impacts.	Potentially Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
No operational impacts would result.			
HYDRO-2. Erosion. See discussion above under *HYDRO-1. Water Quality*. No operational impacts would result.	Potentially Significant	No mitigation measures are required.	Less than Significant
HYDRO-3. Alter Existing Drainage Patterns Resulting in On- or Off-site Flooding. Dewatering of the site would be required, although the exact amount is not known at this time. In addition, construction of the cofferdam in the Grand Canal could substantially alter flows. Compliance with existing regulations and permit requirements would minimize potential impacts. No operational impacts would result.	Potentially Significant	No mitigation measures are required.	Less than Significant
HYDRO-4. Stormwater Drainage Systems. Construction and operation of the Proposed Project would not create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.	Less than Significant	No mitigation measures are required.	Less than Significant
HYDRO-5. Degrade Water	Potentially Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Quality. Both land side and in-water construction activities could result in a discharge of contaminated sediments, removed vegetation, trash, and other metals and hydrocarbons. In addition, although no known contaminated sediments are located at the Project Site, excavated soils may become accidentally contaminated in the event of a construction-related spill and could enter the Grand Canal, Ballona Lagoon, and Ballona Creek (associated with Laydown Area 3 in Culver City), Compliance with existing regulations and permit requirements would minimize potential impacts. No operational impacts would result.			
HYDRO-6. Flooding and 100-year Flood Hazard Areas. Construction and operation of the Proposed Project would not place structures that would impede or redirect flood flows within a 100-year flood hazard area. Placement of a temporary cofferdam in the Grand Canal during construction would not increase flows above the channel banks during storm	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
events, including the 100-year, 24-hour storm.			
HYDRO-7. Contribute to inundation by Seiche, Tsunami, Sea Level Rise or Mudflow. Construction of the Proposed Project would not contribute to inundation by seiche, tsunami, sea level rise, or mudflow. However, the existing VPP and the Proposed VAPP are currently located in a tsunami hazard zone and are already vulnerable to inundation by tsunami impacts. Also, due to their location adjacent to tidal water bodies (i.e. the Pacific Ocean, Grand Canal and Ballona Lagoon), that could rise due to sea level rise and storm surges, the VPP and the Proposed VAPP are vulnerable to flooding from 100-year storm events during operation.	Less than Significant (construction) Significant and Unavoidable	No mitigation measures are required. **MM-HYDRO- 1**: The City of Los Angeles Department of Sanitation shall prepare a Tsunami Response and Action Plan designed for the VPP/VAPP facility by 2020. At a minimum, the plan shall identify and implement specific measures related the VPP/VAPP which are designed to 1) reduce impacts to the facility in the event of a tsunami and/or with future sea level rise conditions and 2) identify what actions are needed at the VPP/VAPP facility and within the wastewater infrastructure system to accelerate the recovery period of the VPP/VAPP facility in the event that a tsunami or major storm event disabled the facilities. These measures shall be implemented at the VAPP by 2022. The action plan could include the following measures: • Evaluate the potential for installing temporary flood barriers as needed when sufficient notice is given; • Evaluate the use of watertight enclosures to further protect electrical equipment, instrumentation and controls before completing final design of the VAPP facility and other LA Sanitation wastewater facilities located within local coastal areas, as appropriate.	Less than Significant (construction) Significant and Unavoidable
HYDRO-8. Instability from Erosion. See discussion above under *HYDRO-1. Water Quality*. No operational impacts would result.	Less than Significant	No mitigation measures are required.	Less than Significant
HYDRO-9.Accelerate Wind and Water Erosion. See discussion above under *HYDRO-1. Water Quality*. No operational impacts would result.	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
HYDRO-10. Create pollution, contamination or nuisance that would violate a water quality standard. See discussion above under *HYDRO-1. Water Quality*. No operational impacts would result.	Less than Significant	No mitigation measures are required.	Less than Significant
HYDRO-11. Cause flooding during the projected 50-year developed storm event. See section above under *HYDRO-6. Flooding and 100-year Flood Hazard Areas*. No operational impacts would result.	Less than Significant	No mitigation measures are required.	Less than Significant
HYDRO-12. Affect Amount of Water Body Surface Water. Construction and operation of the Proposed Project would not substantially reduce or increase the amount of surface water in a water body.	Less than Significant	No mitigation measures are required.	Less than Significant
HYRDO-13. Surface Water Movement. Construction and operation of the Proposed Project would not result in permanent, adverse change to the movement of surface water sufficient to produce a substantial change in the current or direction of water flow.	Less than Significant	No mitigation measures are required.	Less than Significant
Cumulative Impacts. Neither the related projects (see Chapter 1, Introduction [Table 1-1, Related Projects List] of this EIR) nor the	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Proposed Project are expected to adversely affect water quality or hydrology, nor result in effects that are potentially cumulatively significant.			
Land Use and Planning			
PLNG-1. Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project.: Construction and operation of the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the Project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) The Proposed Project would be required to obtain permits and other discretionary actions (see Table 2-1 in Chapter 2, Project Description of this EIR) prior to construction and operation, which would reduce impacts. Because the Proposed Project would represent a new use, it will need to be designed and constructed in a manner that is in keeping with the character of the existing neighborhood and as	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
identified in the City's Municipal Code and other applicable design guidelines.			
PLNG-2. Be inconsistent with the adopted land use/density designation in the Community Plan, redevelopment plan or specific plan for the site: The Proposed Project would not be inconsistent with the adopted land use/density designation in the Community Plan, as shown in Table 3.8-2 (see Section 3.8 [Land Use & Planning] of this EIR).	Less than Significant	No mitigation measures are required.	Less than Significant
PLNG-3. Be inconsistent with the General Plan or adopted environmental goals or policies contained in other applicable plans: Table 3.8-2 (see Section 3.8 [Land Use & Planning] of this EIR) describes impacts related to whether the Proposed Project is inconsistent with the General Plan or adopted environmental goals or policies contained in other applicable plans. As shown in this table, all impacts would be less than significant.	Less than Significant	No mitigation measures are required.	Less than Significant
PLNG-4. Extent of the area that would be impacted, the nature and degree of impacts, and the type of land uses within that area: The	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Proposed Project represents a continuation of the Public Facility use, which was present in the 1950s and was the first urban use in the neighborhood. In addition, the Public Benefits Project section of the Los Angeles Municipal Code permits its construction under its current zoning and general plan land use designations.			
PLNG-5. The number, degree, and type of secondary impacts to surrounding land uses: The analysis contained in this EIR has determined that all impacts, with the exception of construction-related noise and vibration, can be mitigated to less than significant levels with standard regulatory requirements or the implementation of mitigation measures. In the case of construction-related noise and vibration impacts, these would be significant and unavoidable during the construction period, which is expected to last 24 months.	Secondary Impacts (Construction): Significant, due to significant and unavoidable impacts related to construction noise and vibration Secondary Impacts (Operations): Less than Significant	Secondary impacts on surrounding land uses would result from significant construction noise and vibration impacts. MM NOI-1 and MM NOI-2 are required to reduce these impacts. However, even with the application of these mitigation measures, the impacts remain significant and unavoidable. Secondary impacts on surrounding land uses related to noise during operations are addressed with MM NOI-3, which reduces operational noise levels created by building equipment, MM AES-3, which ensures that all Proposed Project structures will be designed to minimize their visual presence, and MM GEO-1, which helps prevent seismically related ground failure, including failure related to liquefaction.	Secondary Impacts (Construction): Significant and Unavoidable; Secondary Impacts (Operations): Less than Significant
Cumulative Impacts. Neither the related projects (see Chapter 1, Introduction [Table 1-1, Related Projects	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
List] of this EIR) nor the Proposed Project are expected to adversely affect land use and planning, nor result in effects that are potentially cumulatively significant.			
Noise and Vibration			
NOI-1. Construction Noise. Construction of the Proposed Project would not result in significant short-term impacts associated with construction-related traffic driving to and from the Project Site or intermittent construction-related noise generated by activities at nearby storage/laydown area(s) outside the Project Site at vacant lots adjacent to the Grand Canal and Ballona Lagoon. However, construction activities would exceed the existing ambient exterior noise levels by 5 dBA or more at a noise-sensitive use. This impact cannot be completely eliminated and would remain potentially significant and unavoidable after implementation of mitigation.	Potentially Significant	**MM NOI-1: Prepare and Implement a Construction Noise Control Plan to Reduce Construction Noise at Noise-Sensitive Land Uses**. To reduce the significant construction noise impacts, the Los Angeles Bureau of Engineering (LABOE) and Contractor shall develop a noise control plan that includes the implementation of the following noise reduction measures during construction: a) Construction activities shall occur only between 8:00 a.m. to 6:00 p.m. Monday through Saturdays. No construction activity shall occur on national holidays or at any time on Sundays. The use of the pile driver, grader and jackhammer construction equipment shall be limited to the hours of 9 a.m. to 3:30 p.m. Haul trucks can only access the site through local neighborhood streets from 9 a.m. to 4 p.m. Construction personnel shall not be permitted on the Project Site (including laydown and storage areas), and material or equipment deliveries and collections shall occur outside of these hours. b) All piles, including sheeting, shall be installed and extracted using vibration- and percussive-free methods. c) To minimize unavoidable noise, LABOE and/or its Contractor shall maintain good communication with the surrounding community regarding the schedule, duration, and progress of the construction. Residents at properties within 500 feet of construction activities shall be notified 72 hours in advance of the planned activities prior to the start of work. The notification shall advise that there will be loud noise associated with the construction, and shall	Significant and Unavoidable

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
		state the date, time, and expected duration of the planned activities. The notification shall provide a telephone contact number for affected parties to ask questions and/or relay concerns. d) To the extent practicable, temporary noise barriers with a minimum height of 20 feet shall be employed around the Project Site. Openings in the barriers shall be kept to the minimum necessary for access of vehicles, equipment, and construction material. These barriers shall be constructed as follows. ○ From commercially available acoustical panels lined with sound-absorbing material (the sound-absorptive faces of the panels shall face the construction equipment); or, ○ From acoustical blankets hung over or from a supporting frame. The blankets shall provide a minimum sound transmission class rating of 28 and a minimum noise-reduction coefficient of 0.80 and shall be firmly secured to the framework with the sound-absorptive side of the blankets oriented toward the construction equipment. The blankets shall be overlapped by at least 6 inches at seams and taped so that no gaps exist. The largest blankets available shall be used in order to minimize the number of seams. The blankets shall be draped to the ground to eliminate any gaps at the base of the barrier. e) For noise-generating equipment that cannot be shielded by site perimeter barriers, localized noise barriers or enclosures shall be employed wherever feasible. The height and location of these barriers/enclosures shall be designed to block the line of sight between the equipment and the surrounding homes. f) LABOE/Contractor shall retain the services of an acoustical/noise consultant to prepare a Noise Monitoring Plan. ○ This shall be a site-specific plan for monitoring and reporting construction noise levels in the community to evaluate the Contractor's performance.	

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
		○ Based on the details of the Contractor's specific construction schedule, the plan shall develop construction noise goals, in terms of the 1-hour Leq, that should be achieved for each phase of construction with the inclusion of feasible and practicable noise abatement measures. ○ If noise monitoring indicates the applicable noise goals have been exceeded, steps shall be taken to promptly implement any additional effective abatement measures that are feasible and/or practicable. g) To the fullest extent practicable, the quietest available type of construction equipment shall be used. Newer equipment is generally quieter than older equipment. The use of electric-powered equipment is typically quieter than diesel- or gasoline-powered equipment, and hydraulic-powered equipment is typically quieter than pneumatic-powered equipment. h) All construction equipment used on the Proposed Project that is regulated for noise output by a local, state, or federal agency shall comply with such regulation while in the course of Project activity and use on site. i) All construction equipment shall be properly maintained. (Poor maintenance of equipment may cause excessive noise levels.) j) All construction equipment shall be equipped with properly operating and maintained mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features that meet or exceed original factory specifications. k) All construction equipment shall be operated only when necessary, and shall be switched off when not in use. Idling inactive construction equipment for prolonged periods (i.e., more than 2 minutes) shall not be permitted. l) The use of noise-producing signals, including horns, whistles, alarms, and bells, shall be for safety warning purposes only.	

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
		m) No Project-related public address or music system shall be audible at any adjacent residential receptor. n) Construction employees shall be trained in the proper operation and use of the equipment. (Careless or improper operation or inappropriate use of equipment can increase noise levels. Poor loading, unloading, excavation, and hauling techniques are examples of how a lack of adequate guidance and training may lead to increased noise levels.) o) Stationary noise sources such as generators and compressors shall be positioned as far as possible from noise sensitive areas. p) Construction equipment shall be stored on the Project Site or designated laydown areas while in use, to the extent feasible. This will eliminate noise associated with repeated transportation of the equipment to and from the site. q) To the extent possible, haul roads shall not be designated through noise-sensitive areas.	
NOI-2 & 3. Construction Vibration. Construction of the Proposed Project would result in ground-borne vibration that would exceed the thresholds developed both for potential annoyance at nearby homes and for potential vibration damage at nearby structures. This impact cannot be completely eliminated and would remain potentially significant and unavoidable after implementation of mitigation.	Potentially Significant	Implement MM NOI-1, as noted above. **MM NOI-2: Implement ground-borne vibration control measures to reduce construction-generated vibration**. To reduce the significant construction vibration impacts, LABOE/Contractor shall implement the following vibration reduction measures during Project construction: a) All piles, including sheeting, shall be installed and extracted using vibration- and percussive-free methods. b) LABOE and/or Contractor shall retain a qualified structural or geotechnical engineer to conduct pre-construction surveys of adjacent neighboring structures (including photographing and/or videotaping) to document existing building conditions for future comparison if any vibration-related damage is suspected or results from construction-related activities. c) If considered appropriate by the structural/geotechnical engineer, monitoring shall be conducted during construction to check for vibration-related damage from equipment	Significant and Unavoidable (annoyance impacts only)

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
		during its use. Such monitoring may include vibration measurements obtained inside or outside of the buildings, or other tests and observations deemed necessary.	
NOISE-3 & 4. Operational Noise. Operation of the Proposed Project could produce noise levels propagating to neighboring properties that could be high enough to raise ambient noise levels by 5 dB CNEL or more.	Potentially Significant	**MM NOI-3: Design Project facilities to reduce noise from all mechanical and electrical equipment to levels that comply with applicable regulations.** To reduce the significant operational noise impacts to less than significant, noise control features shall be included during the final architectural and engineering design phase of the Project, to reduce overall operational noise levels from all Project-related sources to within 5 dB CNEL of existing ambient noise levels in the surrounding community (53 to 57 dB CNEL, as described in Table 3.9-6), and to comply with Chapter XI of the City of Los Angeles Municipal Code (i.e., restrict noise level increases, relative to the existing 1-hour L_{eq}, to 5 dBA or less). The City shall retain an acoustical/noise consultant to evaluate the design and provide recommendations for specific noise-control features, as necessary, feasible, and practicable, based on the final equipment selections and specifications for the Project. Such noise control features may include, but are not limited to, the following: a) Selecting equipment with lower sound power levels. b) Adjusting the location of equipment items within the Project Site to increase the distance from the closest sensitive receptors and/or increase acoustical shielding provided by intervening structures, where practicable and feasible. c) Shielding noise-generating equipment with screens, acoustical panels, enclosures, or block walls. d) Using sound-rated doors, windows, and access hatches at the electrical building and subterranean vault. e) Adding sound-absorptive materials to interior spaces to reduce buildup of reverberant noise levels. f) Designing ventilation systems with acoustical louvres, intake and exhaust silencers, and other features to control exterior noise propagation from interior sources.	Less than Significant
Cumulative Impacts. Impacts associated with noise and	Potentially Significant (construction only)	Implementation of MM NOI-1 and MM NOI-2 (previously described above).	Significant and Unavoidable

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
vibration during construction were determined to be significant and unavoidable. Cumulative impacts during operation would be less than significant.			(construction only)
Transportation/Traffic			
TRANS-1. *Exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness:* The construction traffic impacts associated with the Project would be short-term in nature and limited to the period of time when construction activity is taking place. The primary off-site impacts resulting from the movement of construction trucks would include a short-term and intermittent lessening of roadway capacities due to the slower movements and larger turning radii of the trucks compared to passenger vehicles. Implementation of the Proposed Project would not exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
components of the circulation system			
TRANS-2. Conflict with an applicable congestion management program: The Proposed Project would add up to an estimated 58 daily truck trips related to excavation, material deliveries and worker commutes during the construction phase of the Proposed Project. As such, the Project would not trigger a CMP analysis and implementation of the Proposed Project would not result in a potentially significant impact related to an applicable congestion management program.	Less than Significant	No mitigation measures are required.	Less than Significant
TRANS-3. Result in inadequate emergency access: Construction-related activities have the potential to result in temporary and periodic inadequate emergency access. Wherever possible, delivery trucks would be brought onto the Project Site and be loaded and unloaded within the perimeter fence of the construction site. The roadways surrounding the Project Site would remain	Potentially Significant	**MM TRANS-1: Construction Worker Shuttles.** Construction workers would park at an off-site location and be shuttled to and from the Project Site each workday on 10 to 15-passenger shuttles or vans. While no specific off-site location has been identified at this time, it would likely lie within five miles of the Project Site. The selected contractor would be required to identify and secure a suitable location. In general, work is planned to occur between 8:00 a.m. and 6:00 p.m., and worker shuttles are expected to depart the site by 6:00 p.m. **MM TRANS-2: Coordination with Emergency Service Providers.** Coordinate with emergency service providers (police, fire, ambulance and paramedic services) to provide advance notice of any lane closures, construction hours and changes to local access and to identify alternative routes where	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
accessible during operation of the Proposed Project. Operational impacts would be less than significant.		appropriate.	
TRANS-4. . Result in In-Street Construction Impacts: Based on City of Los Angeles guidelines, VAPP construction activity would not result in any significant traffic impacts on study area streets because the maximum number of daily Project trips is estimated to be 108 1-way trips, which is below the minimum threshold volume considered significant. The Proposed Project would not result in in-street construction impacts related to temporary loss of access and impacts. The Proposed Project would not result in in-street construction impacts related to temporary loss of bus stops or rerouting of bus lines. A portion of Hurricane Street and Canal Court would be temporarily closed. This impact could be adverse during peak hours, but is not considered to be significant because of the temporary nature of the construction activities.	Less than Significant	No mitigation measures are required.	Less than Significant
Cumulative Impacts.	Less than significant.	No mitigation measures are required.	Less than significant.

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
With regards to cumulative traffic impacts during construction, of the eight related projects (see Chapter 1, Table 1-1) only two (Via Dolce Park and Venice Dual Force Main), have identified construction schedules that would overlap with VAPP. As shown in Table 3.10-1, two of the six study intersections were projected to operate at unacceptable levels of service of E or F during one or both peak hours. Construction traffic generated by the two related projects could result in additional congestion at these and other intersections in the project area. As discussed in the VAPP construction impact analyses above, the Proposed Project could generate up to 48 daily vehicle trips during the construction period. Those vehicle trips, combined with the construction vehicle trips due to the related projects, could cumulatively exacerbate already congested conditions at study area intersections. However, the impacts due to construction traffic would be temporary, and as noted above, the City of Los Angeles considers			

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
construction-related traffic impacts adverse but not significant because such impacts, while sometimes inconvenient, are only temporary.			
Energy			
ENERGY-1. New off-site energy supply facilities and distribution infrastructure: No new or expanded sources of energy or infrastructure would be required to meet the energy demand under construction. Under operation, energy consumption would be a nominal addition to the regular energy use.	Less than Significant	No mitigation measures are required.	Less than Significant
ENERGY-2. Whether needed infrastructure was anticipated by adopted plans: Given the extensive network of fueling stations throughout the Project vicinity, the existing fuel infrastructure is expected to accommodate the increased construction-period demand for fuel introduced by the Proposed Project. The proposed Project is consistent with wastewater provisions contained in the Framework Element of the City of Los Angeles General Plan. The Bureau of	Less than Significant	No mitigation measures are required.	Less than Significant

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
Engineering has programmed the Proposed Project as part of its Wastewater – Collection System Program. The Los Angeles Department of Water and Power (LADWP) has adopted the Power Integrated Resource Plan to manage the electricity needs of the city's inhabitants, which includes energy used for wastewater pumping.			
ENERGY-3. Degree to which the project design and/or operations incorporate energy conservation measures: All equipment would be used in compliance with the manufacturer's specifications. As such, construction of the Proposed Project is not expected to result in the wasteful or inefficient use of energy. The Proposed Project would be as efficient as possible and would include variable frequency drives on for the pumps for maximum efficiency and the electrical building would be constructed in compliance with the City's Building Code, including its Green Building Code.	Less than Significant	No mitigation measures are required.	Less than Significant
Cumulative Impacts: The natural gas and fuel use that would result from Project	Potentially Significant	No mitigation measures are available.	Significant and Unavoidable.

Environmental Impact	Significance Before Mitigation	Mitigation Measures	Significance after Mitigation
implementation would be negligible relative to the regional market. However, the increase electricity consumption associated with the Proposed Project in combination with future projects within LADWP's service area may require new electricity transmission infrastructure or the rehabilitation of existing electricity infrastructure to meet the increased demand and maintain adequate levels of service. Where LADWP has identified specific individual projects that are required to meet future projected regional cumulative demands and determined that construction or operation of those projects would result in significant impacts to the environment, then the cumulative impact of the Proposed Project and other projects in the LADWP service area would be considered significant.			

Chapter 1
Introduction

This chapter presents background information for the proposed Venice Auxiliary Pumping Plant (VAPP) Project (Proposed Project), including:

- The authority of the lead agency, the City of Los Angeles Bureau of Engineering (LABOE), to prepare this Draft Environmental Impact Report (EIR);
- The purpose of the environmental review process;
- The scope, content, and intended uses of the Draft EIR;
- Public outreach efforts during the California Environmental Quality Act (CEQA) process;
- Key principles guiding the preparation of this Draft EIR; and
- Related projects considered when analyzing the potential for cumulative environmental impacts.

1.1 Background and Project Overview

The City of Los Angeles (City) owns and operates the Venice Pumping Plant (VPP) (Pump Station No. 646), located at 140 Hurricane Street in the Los Angeles community of Venice. The largest of the City's pumping plants, the VPP is considered a critical facility for conveying sewage. The facility was built in 1957 and expanded and upgraded in 1987. Two duty and three backup pumps currently serve the facility. The VPP collects sewage from the City's Coastal Interceptor Sewer (CIS), which serves the communities of Topanga, Pacific Palisades, Brentwood, Venice, and Mar Vista. It also services Santa Monica and parts of Los Angeles County. Sewage from the CIS is pumped south via the VPP to the City's Hyperion Treatment Plant, located in Playa del Rey. Unlike other portions of the City's sewage collection and conveyance system, there are currently no diversions for bypassing the facility or associated CIS for required maintenance or in the event of an emergency. Moreover, the existing VPP is essentially built out and has no additional space for the additional backup pumps and associated equipment required to ensure future system reliability.

During dry-weather flows (when no rain occurs), the two duty pumps serve the facility and pump about 20 million gallons per day (mgd) of sewage. During wet-weather flows (rain), as much as 50 mgd of sewage may be pumped by the facility, requiring all five pumps to be in operation simultaneously. On several occasions, during extreme weather events (e.g., 1990s and 2000s), the flows exceeded the combined simultaneous pumping capacity of the facility, resulting in near-miss events, which would have required emergency discharges directly to the Grand Canal and Ballona Lagoon or overflows into the surrounding street network. To address these issues, LABOE and LA Sanitation began planning and designing projects that would upgrade and enhance the CIS and VPP (see Chapter 2, Project Description), including the proposed VAPP project.

As currently proposed (see Figure 2-4, Site Plan, in Chapter 2), the VAPP would include construction of an auxiliary pumping facility on two vacant City-owned parcels, located adjacent to the VPP. The new facility would provide additional reliability and be sized to supplement the pumping capacity of the VPP, for a combined ultimate peak-flow capacity of 87 mgd, reflecting wet-weather flows during

a 10-year storm event. The facility would also allow regular service and maintenance activities to occur without creating concern that pumping capacity during these times would not be adequate to handle increased wet-weather flows. With upgraded system redundancy and reliability, the potential for near misses and/or catastrophic system failures during maintenance periods would be reduced.

As part of the Proposed Project, a number of system improvements would be implemented, both above and below ground, including a new electrical building, housing the control system and employee workstations; three new underground and submersed pumps; a backup generator; sewer pipe connections to the CIS, including construction of a diversion structure beneath the Grand Canal; and parking, public art, and open space. Combined, the five existing pumps at the VPP and the three new pumps would have a rated capacity of 87 mgd (i.e., five duty pumps and three standby). All pumps would have a similar capacity and be functionally equivalent. Please see Chapter 2 for a more detailed description of the Proposed Project.

Construction is anticipated to begin in February 2018 and last approximately 2 years.

1.2 Purpose and Intended Use of This EIR

The purpose of this Draft EIR is to inform decision-makers and the general public of the potential environmental impacts that could result from the Proposed Project. An EIR is the most comprehensive form of environmental documentation under CEQA and the State CEQA Guidelines. It provides the information needed to assess the environmental consequences of a proposed project, to the extent feasible. EIRs are intended to provide an objective, factually supported full-disclosure analysis of the environmental consequences associated with a proposed project that has the potential to result in significant, adverse environmental impacts. An EIR is one of the various decision-making tools used by a lead agency to consider the merits and disadvantages of a project that is subject to its discretionary authority.

CEQA requires the decision-making body to balance, as applicable, the economic, legal, social, or other benefits of the project against the unavoidable environmental risks when determining whether to approve the project. If the specific economic, legal, social, or other benefits of the project outweigh the unavoidable significant environmental impacts, the significant environmental impacts may be considered acceptable, and the lead agency will adopt a Statement of Overriding Considerations (SOC). When the lead agency approves a project that will result in significant impacts, as identified in the EIR, but the impacts are not avoided or substantially lessened, the SOC is the document that contains the specific reasons that support the agency's decision, based on the Final EIR and/or other information in the administrative record. The SOC must be supported by substantial evidence in the record, including findings. In addition, pursuant to Section 21081.6 of CEQA, when approving a project, public agencies must also adopt a mitigation monitoring plan or program for changes that were incorporated into the project or made a condition of project approval to mitigate or avoid significant environmental impacts.

The project owner is LA Sanitation. LABOE is responsible for obtaining the required environmental and planning permits and approvals as well as designing and constructing the Proposed Project. A description of the Proposed Project is provided in Chapter 2 of this Draft EIR.

The Proposed Project requires certain discretionary approvals from the City of Los Angeles and other public agencies (see below and Chapter 2). Therefore, the Proposed Project is subject to environmental review requirements under CEQA.[1] The City of Los Angeles is the lead agency under CEQA for the Proposed Project.

As described in Sections 15121(a) and 15362 of the State CEQA Guidelines, an EIR is an informational document that informs public agency decision-makers and the public of the significant environmental effects of a project, identifies possible ways to minimize the significant effects, and describes reasonable alternatives to the project. The purpose of this Draft EIR, therefore, is to focus the discussion on those potential effects of the Proposed Project on the environment that the lead agency has determined may be significant. In addition, feasible mitigation measures are recommended, when applicable, to reduce or avoid significant environmental impacts.

The EIR is prepared by and under the direction of LABOE, which also has primary responsibility for recommending approval of and implementing the Proposed Project. Project approval and certification of the EIR must be considered by the Los Angeles City Council.

As shown in Figure 1-1, EIR Process Overview, an EIR is prepared in three key stages. The CEQA process is initiated when the lead agency identifies a proposed project. The lead agency then normally prepares an Initial Study to identify the preliminary environmental impacts of the Proposed Project. The Initial Study for the VAPP project determined that the Proposed Project could have significant environmental impacts that would require further study and implementation of mitigation measures. Therefore, the lead agency has decided to prepare an EIR. A Notice of Preparation (NOP) is prepared to notify public agencies and the general public that the lead agency is starting the preparation of an EIR for the Proposed Project. The NOP and Initial Study are circulated for a 30-day review and comment period. During this review period, the lead agency requests comments from agencies, interested parties, stakeholders, and the general public on the scope and content of the environmental information to be included in the Draft EIR.

Figure 1-1. EIR Process Overview

[1] Public Resources Code Sections 21000–21189.3.

After the close of the 30-day review and comment period, the lead agency continues the preparation of the Draft EIR and associated technical studies (if any). Once the Draft EIR is complete, a Notice of Availability (NOA) is prepared to inform agencies and the general public of the document and the locations where the document can be reviewed. The Draft EIR and NOA are circulated for a 45-day review and comment period to provide agencies and the general public an opportunity to review and comment on the adequacy of the analysis and the findings regarding potential environmental impacts of the Proposed Project.

After the close of the 45-day review and comment period, responses to all comments received on the Draft EIR are prepared. The lead agency prepares a Final EIR, which incorporates the Draft EIR or a revision to the Draft EIR, Draft EIR comments and a list of commenters, and responses to comments. In addition, the lead agency must prepare the findings of fact for each significant effect identified; the SOC, if there are significant impacts that cannot be mitigated; and a mitigation monitoring and reporting program to ensure that all proposed mitigation measures are implemented.

The Board of Public Works will consider the Final EIR and make a recommendation to the Los Angeles City Council, as the governing body of the City of Los Angeles, regarding certification of the Final EIR and project approval. The City Council may certify and approve the Final EIR or may choose to not approve the project.

During the environmental review and project approval process, people and/or agencies may address the Board of Public Works and City Council regarding the Proposed Project. Public notification of agenda items for the Board of Public Works are available here:

http://bpw.lacity.org/Agendas.html

City Council agenda items are posted 72 hours prior to the public meeting. The City Council agenda can be obtained by visiting the City Council:

City Hall
200 North Spring Street
John Ferraro Council Chamber, Room 340
Los Angeles, CA 90012

Alternatively, agendas can also be accessed via the Internet at the following location:

http://lacity.org/city-government/elected-official-offices/city-council/council-calendar

Within 5 days of project approval, the LABOE will file a Notice of Determination (NOD) with the County Clerk. The NOD will be posted by the County Clerk within 24 hours of receipt. This begins a 30-day statute of limitations on legal challenges to the CEQA approval by the lead agency. The ability to challenge the approval in court may be limited to those persons who objected to the approval of the Proposed Project and issues that were presented to the lead agency by any person in writing during the public review and comment periods regarding the EIR.

The Final EIR is used by the recommending bodies (LABOE) and the final decision-makers (City Council) to weigh the environmental impacts against the benefits of the Proposed Project.

1.3 Scope and Content of the Draft EIR

In accordance with the requirements of CEQA, the City prepared an Initial Study (see below), dated November 12, 2015, which identified the topics to be analyzed in the EIR. The Initial Study is contained in Appendix A (Notice of Preparation/Initial Study) of this Draft EIR.

Because the analysis contained in the Initial Study determined that the Proposed Project would result in less-than-significant or no impacts related to agriculture and forestry resources, hazards and hazardous materials, mineral resources, population and housing, public services, and recreation, no further analysis is required in the EIR. Therefore, the focus of this EIR has been limited to the following environmental impact areas:

- Aesthetics
- Air Quality
- Biological Resources
- Cultural Resources
- Geology and Soils
- Greenhouse Gas Emissions
- Hazards and Hazardous Materials
- Hydrology and Water Quality
- Land Use and Planning
- Noise and Vibration
- Transportation/Traffic
- Utilities and Service Systems[2]
- Energy

It should be noted, however, that the required sections and analysis, per CEQA (see Section 1.5, below), are included in this Draft EIR.

1.3.1 Notice of Preparation/Initial Study

In accordance with Section 15082 of the State CEQA Guidelines, LABOE prepared a Notice of Preparation/Initial Study (NOP/IS) for the Proposed Project on November 12, 2015. The NOP was circulated for 30 days. The comment period ended on December 18, 2015. The NOP was also published in the *Los Angeles Times* and *The Argonaut*.

This notice was circulated to members of the public, local and state agencies, and other interested parties to solicit comments on the Proposed Project. Concerns raised in response to the NOP were considered during preparation of this Draft EIR (see Table ES-2 in the Executive Summary of this Draft EIR). The NOP, comment letters received, and Initial Study are presented in Appendix A of this Draft EIR.

[2] This environmental parameter is addressed in Section 3.7, Hydrology and Water Quality, of this Draft EIR.

The NOP was sent to the California Governor's Office of Planning and Research, State Clearinghouse, for further responsible and trustee agency distribution and issuance of a state identification number, which will be referenced on all subsequent correspondence regarding the project.

The NOP/IS was made available at local public facilities, including the Venice – Abbot Kinney Memorial Branch Library, Lloyd Taber – Marina del Rey Library, and the Playa Vista Branch Library, as well as the LABOE web site, http://eng.lacity.org/techdocs/emg/venice_aux_pumping_plant.htm.

Comment letters regarding the NOP were received from the following agencies, groups, and individuals:

- U.S. Army Corps of Engineers (Department of the Army, Los Angeles District)
- California Department of Transportation, District 7
- California Department of Fish and Wildlife
- Gabrieleno Band of Mission Indians – Kizh Nation
- John Tommy Rosas
- Fernandeno Tataviam Band of Mission Indians
- County of Los Angeles Department of Public Works and Department of Beaches and Harbors
- Steve Bradbury
- Morrill Borassi
- Bob Debiase
- Mike Borassi
- Walter Lamb
- Los Angeles Waterkeeper (Arthur Pugsley)
- McQueen-Whalen Revocable Trust (Daniel P. Whalen and Sharon McQueen)
- Barbara Brunasso
- Clare Bronowski
- Gary Wells
- Michael Rosenfield
- William Boyd

1.3.2 Public Outreach Efforts

To solicit public input on the issues proposed for consideration in the EIR, two scoping meetings were held. The December 3, 2015, meeting was at 6:00 p.m. at Venice Foursquare Church, 1400 Riviera Avenue, Venice, CA 90291. The December 8, 2015, meeting was at 6:00 p.m. at Abbot Kinney Memorial Branch Library, 501 South Venice Boulevard, Venice, CA 90291. The purpose of the scoping meetings was to provide information regarding the Proposed Project and the CEQA process and receive public comments regarding the scope and content of the Draft EIR. The comments made at the scoping meeting included concerns about biological resources, hydrology and water quality, noise, air quality, and traffic (see Appendix A of this Draft EIR).

1.4 Responsible and Trustee Agencies and Project Approvals

Under CEQA, a responsible agency is a public agency, other than the lead agency, that has responsibility to carry out or approve a project (Public Resources Code [PRC] Section 21069). A trustee agency is a state agency that has jurisdiction by law over natural resources that are held in trust for the people of the State of California (PRC Section 21070).

The following agencies may be required to provide project approvals and/or permits (see also Table 2-1, Required Permits for Venice Auxiliary Pumping Plant in Chapter 2, Project Description, of this EIR):

- City of Los Angeles
- County of Los Angeles
- City of Culver City
- Los Angeles Regional Water Quality Control Board
- South Coast Air Quality Management District
- California Coastal Commission
- California Department of Conservation, Division of Oil, Gas, and Geothermal Resources
- State of California Department of Health Services
- California Office of Historic Preservation
- U.S. Army Corps of Engineers
- National Marine Fisheries
- U.S. Fish and Wildlife Service

1.5 Organization of the Draft EIR

This Draft EIR conforms to the content requirements stated in Sections 15120 through 15132 of the State CEQA Guidelines. A list of the document's chapters, including and a brief description of their content, is provided here to assist the reader in locating information.

Executive Summary: Located at the front of this document, the Executive Summary provides a brief description of the Proposed Project, including an overview of the impact analysis, recommended mitigation measures, and net residual impact.

Chapter 1: Introduction: The Introduction provides general background information regarding project development and the need for the Proposed Project, along with information regarding the purpose of CEQA and this Draft EIR, including the Draft EIR scoping process; the availability of documents; and the Draft EIR review process.

Chapter 2. Project Description: Chapter 2 presents a statement of the Proposed Project's objectives, a description of the location and setting of the Proposed Project, a detailed description of the Proposed Project's physical characteristics, and related information on phasing and implementation.

Chapter 3. Environmental Impact Analysis: This chapter analyzes the potential impacts (direct and indirect) that could occur as a result of implementation of the Proposed Project. The impact discussion is organized by topical issue (i.e., issues that have been found to have the potential to result in significant impacts).

Chapter 4. Comparison of Alternatives: The Comparison of Alternatives includes a discussion of the proposed alternatives and provides the comparative merits of each alternative.

Chapter 5. Other Environmental Considerations: Chapter 5 evaluates the contextual impacts related to growth-inducing effects and cumulative growth. Impacts found not to be significant and unavoidable adverse impacts are also summarized.

Chapter 6. Persons Consulted: This chapter lists those persons who were consulted to obtain the information that was used in the preparation of this Draft EIR.

Chapter 7. List of Preparers: This chapter lists the persons who prepared this Draft EIR.

Chapter 8. References: This chapter lists the sources of information that were referenced for the analyses contained within this Draft EIR.

1.6 Related Projects

In combination with the VAPP, the related projects described below will provide system reliability and redundancy and allow influent flows from the CIS to be bypassed to the Venice Dual Force Main (VDFM) during extreme weather events or an unforeseen emergency.

1.6.1 Venice Dual Force Main

The VDFM is a new 54-inch-diameter force main in the vicinity of the VPP and proposed VAPP. The new pipeline alignment will cross the Grand Canal from the VPP, extend northerly along Hurricane Street to Marquesas Way, then continue southerly along Via Marina before crossing the Marina Del Rey and Ballona Creek channels to the CIS Diversion Structure on Vista del Mar near Waterview Street. The new force main will operate as a parallel system in conjunction with the existing 48-inch force main to meet the peak wet-weather flow demands experienced at the VPP and add operational flexibility and reliability. The City anticipates finishing construction on the VDFM by 2019.

1.6.2 VPP Manifold Replacement Project

The VPP Manifold Replacement Project was recently completed (August 2015) within Hurricane Street. That project consisted of removing the existing manifold structure located within Hurricane Street, between Canal Court and the Esplanade, and installing a new 60-inch steel manifold with connections to the VPP, the existing 48-inch force main, and stub-outs at both ends for connection to the future 54-inch VDFM and planned VAPP.

1.6.3 Venice Pumping Plant Generator Replacement

The project includes demolition of the existing diesel-fueled standby engine/generators and procurement/installation of two new 750-kilowatt (kW) generators and one new 1,500 kW generator with ancillary controllers, transfer switches, exhaust and cooling systems, and fluid storage.

Table 1-1 is the related projects list for the Proposed Project.

1.7 Key Principles Guiding Preparation of This Draft EIR

1.7.1 Forecasting

In this Draft EIR, LABOE has made its best effort to predict and evaluate the reasonable, foreseeable, direct, indirect, and cumulative environmental impacts of the Proposed Project and alternatives. CEQA does not require LABOE to engage in speculation about impacts that are not reasonably foreseeable (CEQA Guidelines Sections 15144, 15145). In these instances, CEQA does not require a worst-case analysis.

1.7.2 Reliance on Environmental Thresholds and Substantial Evidence

The identification of environmental impacts as significant or less than significant is one of the important functions of an EIR. Although impacts determined to be less than significant need only be acknowledged as such, an EIR must identify mitigation measures for any impact identified as significant. In preparing the document, LABOE has based its conclusions about the significance of environmental impacts on identifiable thresholds, specifically those from the State CEQA Guidelines (Appendix G) and *L.A. CEQA Thresholds Guide,* and has supported these conclusions with substantial scientific evidence. It should be noted that the thresholds of significance contained within the Draft EIR reflect only those that were not previously eliminated in the Initial Study (see Appendix A of this Draft EIR). As such, only those remaining thresholds not addressed in the Initial Study and derived from CEQA Appendix G and the *L.A. CEQA Thresholds Guide* are evaluated.

1.7.3 Disagreement Among Experts

It is possible that evidence that might raise disagreements will be presented during the public review of this EIR. Such disagreements will be noted and will be considered by the decision makers during the public hearing process. In accordance with the provisions of CEQA Guidelines, any conflict of evidence and expert opinions on an issue concerning the environmental impacts of the Proposed Project—when LABOE knows of these controversies in advance—has been identified in the Draft EIR. The Draft EIR has summarized conflicting opinions and included sufficient information to allow the public and decision-makers to make an informed judgment about the environmental consequences of the Proposed Project.

Table 1-1. Related Projects List

	Project Name	Type of Project	Description	Status	Start Date	Completion Date	Distance
1.	Via Dolce Park	Park	Construction of a 6,400-square-foot park adjacent to the Grand Canal.	Planned	8/30/2017	6/1/2018	0.2 mi
2.	Marina Beach General Improvements Project	Beach/Park	Refurbishment of existing restroom building, installation of Americans with Disabilities Act (ADA) upgrades, replacement of covered group picnic shelter/shade structures, resurfacing of waterfront promenade, and installation of bioswale planters.	Planned	1/2017	6/2017	0.37 mi
3.	Via Marina Street Improvement Project	Infrastructure	Roadway resurfacing; curb, gutter, and sidewalk repair; and new landscaping in medians.	Contingent on funding			0.5 mi
4.	Admiralty Way at Via Marina Roadway Project	Infrastructure	Reconfiguration of existing 'T' intersection to create additional left-turn pockets. Work to include reconstruction of medians, sidewalks, curbs, and gutters; relocation of catch basins, streetlights, and two bus pads; traffic signal upgrade; and striping.	Contingent on funding			0.4 mi
5.	Venice Dual Force Main	Infrastructure	New 54-inch-diameter force main sewer that will operate as a parallel system in conjunction with the existing 48-inch force main to meet peak wet-weather flow demands experienced at VPP. Valve vaults to be constructed and discharge piping manifold at VPP to be replaced.	Planned	9/2016	11/30/2019	0.0 mi
6.	Washington Boulevard at Venice Canals, Culvert Rehabilitation	Infrastructure	Rehabilitation of five (110-foot by 36-inch) concrete culverts; repair of voids beneath roadway; reconstruction of sidewalks, curbs, and gutters; and street resurfacing.	Planned	3/2/2016	8/31/2016	0.34 mi

	Project Name	Type of Project	Description	Status	Start Date	Completion Date	Distance
7.	Venice Pumping Plant Vibration Rehabilitation, Phase 2	Infrastructure	Rehabilitation to reduce vibration levels at the VPP.	Under Construction	1/13/2016		0.01 mi
8.	Venice Pumping Plant Generators Replacement	Infrastructure	Demolition of existing diesel-fueled standby engine/generators and procurement/installation of two new 750 kW generators and one new 1,500 kW generator with ancillary controllers, transfer switches, exhaust and cooling systems, and fluid storage.	Planned	10/2/2016	1/31/2020	0.01 mi

1.8 Review of the Draft EIR

This Draft EIR will be circulated for review and comments from the public and other interested parties, agencies, and organizations for over 45 calendar days, beginning on October 27, 2016, and closing on December 8, 2016. A public meeting on the Proposed Project will be held on November 17, 2016, at the Venice Foursquare Church. A notice regarding the public review period and time and location for the meeting will be published in the *Los Angeles Times* and *The Argonaut* prior to the public hearing date.

During the public comment period, all comments or questions about the Draft EIR should be addressed to:

Dr. Jan Green Rebstock, Environmental Supervisor II
Los Angeles Bureau of Engineering
Environmental Management Group
1149 South Broadway, Suite 600, Mail Stop 939
Los Angeles, CA 90015-2213
Email: jan.green.rebstock@lacity.org

Following public review of the Draft EIR, a Final EIR will be prepared in response to comments received during the public review period. The Board of Public Works will consider the project and make recommendations to the Los Angeles City Council, the governing body of the City of Los Angeles, regarding certification of the Final EIR and project approval. The City Council may certify and approve the Final EIR or may choose not to approve the project.

The Final EIR will be available for public review at least 10 days prior to its certification (State CEQA Guidelines Section 15088(b)). All responses to comments submitted on the EIR by public agencies will be provided to those agencies at least 10 days prior to final action on the project. The City Council will make findings regarding the extent and nature of the impacts, as depicted in the Final EIR.

During the environmental review and project approval process, people and/or agencies may address the Board of Public Works and City Council regarding the Proposed Project. Public notification of agenda items for the Board of Public Works is available here:

http://bpw.lacity.org/Agendas.html

City Council agenda items are posted 72 hours prior to the public meeting. The City Council agenda can be obtained by visiting the City Council:

City Hall
200 North Spring Street
John Ferraro Council Chamber, Room 340
Los Angeles, CA 90012

Alternatively, agendas can also be accessed by Internet at the following location:

http://lacity.org/city-government/elected-official-offices/city-council/council-calendar

Within 5 days of project approval, LABOE will file a NOD with the State Clearinghouse and County Clerk. The NOD will be posted by the County Clerk within 24 hours of receipt. This begins the 30-day statute of limitations on legal challenges to CEQA approval by the lead agency. The ability to challenge the approval in court may be limited to those persons who objected to approval of the Proposed Project and issues that were presented to the lead agency by any person in writing during the public review and comment periods for the EIR.

Chapter 2
Project Description

This chapter presents the project description for the proposed Venice Auxiliary Pumping Plant (VAPP) Project (Proposed Project), including:

- Project objectives, project location, environmental setting, surrounding land uses, zoning, and land use designations;
- Project background, project overview, project description, and operational requirements;
- Aboveground facilities, parking, belowground facilities, odor control, utilities and services;
- Landscape drainage, site security, circulation, parking and pedestrian, and green space;
- Operations and maintenance and construction stages; and
- Relationships to other projects and project schedule.

2.1 Project Objectives

The Proposed Project is intended to meet the following objectives:

- Prevent potential impacts on human and environmental health caused by sewage spills from the existing VPP during extreme wet-weather events;
- Increase reliability to the system by providing redundancy to pumping capacity to improve system reliability and allow regular service and maintenance activities to take place without compromising the ability of the City to maintain pumping capacity and minimize the risk of sewage overflows; and
- Address future risks related to climate change, including increased storm intensities and sea-level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP.

2.2 Project Location

The Project Site comprises three undeveloped residential lots, zoned Residential Water Ways (RW2-1), a total of 12,076.5 square feet. All three lots are owned by the City of Los Angeles and located next to the existing VPP. The addresses are 3813 and 3817 South Esplanade (Assessor's Parcel Numbers [APNs] 4225-008-904 and 4225-008-904, respectively) (north parcels) and 128 Hurricane Street (APN 4225-010-016) (west parcel). The three lots are not contiguous; however, their functions are integrative and needed to operate the VPP and VAPP as one facility. The west parcel comprises a single oblong lot west of the VPP that measures 85 by 60 feet. The north parcels, comprising two abutting parcels located north of the VPP, are approximately 90 feet long and 70 feet wide combined. Canal Court separates the VPP from the west parcel. Hurricane Street separates the VPP from the north parcels. The VPP manifold is underneath this portion of Hurricane Street (between Canal Court and Esplanade).

Figure 2-1, Project Vicinity Map, shows the location for the proposed VAPP in relation to the City and adjacent cities and communities. The Project Site is within the Ballona Lagoon West sub area of the Venice Community Planning Area and Council District 11.

Figure 2-2, Project Location Map, shows the three construction Laydown Areas that will be used for materials and equipment storage and for construction staging during the anticipated 2-year construction period. Laydown Area 1 is located at 128 Hurricane Street, which is already part of the Project Site. Laydown Area 2 is comprised of two lots that are located at 3819 and 3821 Via Dolce (APNs 4225-013-153 and 4225-013-904, respectively). This site is approximately 6,979 square feet (combined) in size is located across the Venice Grand Canal, east of the Project Site and is accessed from Via Dolce. Laydown Area 3 (APN 4296-001-270) is located at 9940 Jefferson Boulevard in Culver City, which is approximately 7 miles east of the Project Site. Laydown Area 3 is owned by the City of Los Angeles and approximately 198,735 square feet in size.

2.3 Environmental Setting

As shown in Figure 2-2, Project Location Map, the front eastern property lines of 3813 and 3817 South Esplanade abut the Venice Grand Canal and are bounded by Canal Street to the west, Hurricane Street to the south, and multi-family residential to the north. The 128 Hurricane Street southern property line abuts Ballona Lagoon and is bounded by Hurricane Street to the north, Canal Court to the east, and multi-family residential to the west. The Esplanade, which is publicly accessible, connects the Ballona Lagoon trail with the California Coastal Trail at Washington Boulevard, 1,830 feet north of the Project Site. The Project Site is located within the California Coastal Zone. The Grand Canal and Ballona Lagoon (components of the Venice Canal System) are designated as Environmentally Sensitive Habitat Areas (ESHAs) by the California Coastal Commission, County of Los Angeles, and City of Los Angeles. The Venice Canal System, located adjacent to the Project Site, is a City of Los Angeles Historic-Cultural Monument (No. 270) and part of the Venice Historic Canal District (ZI–2370). The Project Site is also located within City Council District 11 and the Venice Community Planning Area (Ballona Lagoon West). The Project Site is classified as being within a liquefiable zone, a tsunami inundation zone, and a methane zone. The 128 Hurricane Street parcel is the site of an abandoned oil well and the overall Project Site is within the Playa del Rey oil/gas field and near other plugged and/or abandoned wells. Applicable plans include the Venice Local Coastal Plan Land Use Plan, Venice Specific Plan, and Coastal Corridor Transportation Specific Plan. The Proposed Project is subject to local City of Los Angeles Residential Design Standards and the Cultural Affairs Public Works Improvement Arts Program.

The VPP is one of five City-owned and operated pumping plants and part of the Hyperion Treatment Plant (HTP) service area (see Figure 2-3, Hyperion System). The HTP is located on a 144-acre site adjacent to Santa Monica Bay, southwest of Los Angeles International Airport (LAX) and approximately 4 miles south of the VPP. The area served by the HTP covers approximately 328,000 acres of the Los Angeles metropolitan area. The HTP, the largest treatment facility in the City, was designed and constructed to be a high-rate secondary treatment facility. The HTP provides primary treatment for all influent flow. The HTP is also the City of Los Angeles' main treatment facility for recycled water. Hyperion Treatment Plant is a recycled water source for the West Basin Municipal Water District, a public agency that provides recycled water from Hyperion to the cities of Carson, El Segundo, Gardena, Hawthorne, Hermosa Beach, Inglewood, Manhattan Beach, Lawndale, Redondo Beach, and unincorporated areas of Los Angeles County within its service area, as well as the cities of Torrance and Los Angeles, which are outside of its service area.

Figure 2-3
Hyperion System
Venice Auxiliary Pumping Plant Project

The HTP receives sewage from five major interceptor sewer systems, including the Coastal Interceptor Sewer (CIS). The CIS runs parallel to the coastal area of the City and includes a collection service area that encompasses the communities of Topanga, Pacific Palisades, Brentwood, Venice, and Mar Vista. It also services Santa Monica and parts of Los Angeles County. The CIS conveys untreated sewage flows from the collection area to the VPP via a 48-inch force main. Because of inadequate hydraulic head (liquid pressure), sewage flows from the CIS that enter the VPP must be continuously pumped in order to reach the HTP. The VPP is the City's largest pumping plant. Within the immediate vicinity of the VPP, the CIS parallels the Grand Canal. An emergency sewer discharge pipe is located within the Grand Canal. In an emergency, flows can be diverted to the Ballona Lagoon.

2.4 Surrounding Land Uses

The Project Site is highly urbanized within the Ballona Lagoon West sub-area of Venice, north of Ironside Street. It contains a mix of residential, open space, and public facility land uses. The Proposed Project is considered infill development. North and west of 3813 and 3817 South Esplanade are single and multi-family residential uses. To the east is the Venice Canal System, which is designated as open space. To the south is the VPP, which is a public facilities land use.

The 128 Hurricane Street parcel is bounded by the Ballona Lagoon to the south, Hurricane Street to the north, multi-family residential to the west, and Canal Court and the VPP to the east.

2.5 Land Use Designation and Zoning

The Project Site is currently vacant, comprising three unimproved lots. These are zoned under the City of Los Angeles Planning and Zoning Code as RW2–1; the City of Los Angeles Venice Community Plan land use designation is Residential/Medium Residential (see Section 3.8, Land Use and Planning, for more details). Laydown Area 3 in Culver City is zoned Industrial General (IG).

2.6 Background

The City owns and operates the VPP (Pump Station No. 646), located at 140 Hurricane Street in the Los Angeles community of Venice, adjacent to Ballona Lagoon and the Grand Canal. The plant is the City's largest pumping plant and considered a critical facility for conveying sewage from its tributary area (described above). It also serves as the control facility for all pumping stations that operate in the City. The facility, designed and built in 1957, includes a control facility and five pumps (two duty and three backup). The VPP has two levels, one above ground and one below, for equipment, emergency generators, and a control center. The facility is manned and operated 24 hours per day, 7 days per week by system operators by six employees (two per shift). Two off-street parking spaces are available for deliveries and the operator(s). The entire facility is gated and closed to the public. The VPP is also equipped with an exhaust fan that discharges vapors through an existing stack. In addition, wet wells (holding sumps for sewage) and associated pumps are located underground, within a sealed and enclosed facility, to minimize odor discharges. The facility was last upsized and upgraded in 1987. At that time, five new pumps were installed (two duty and three backup). The existing VPP is essentially built out and has no

additional space for required backup pumps and associated equipment necessary to convey sewage flowing during peak wet-weather events, including the emergency generators that would be needed to run the pumps in the event of a power failure.

As noted above, the VPP pumps sewage from the City's CIS collection area to the HTP. There are currently no sewage diversions for bypassing the pumping plant. Therefore, unlike other portions of the City's sewage conveyance system where diversions are in place to minimize demand and reliance upon pumping plants, the CIS currently has no redundant or parallel facilities that can be used to redirect flows from these communities.

Flows enter the VPP from a single 66-inch reinforced concrete sewer pipe depressed approximately 18 feet below ground within the Grand Canal that discharges into two existing wet wells. Wet well No. 1 serves Pumps 1 through 4, and wet well No. 2 serves Pump 5. Each of the five 400-horsepower dry-pit centrifugal pumps has a design capacity of 18 million gallons per day (mgd) at 100 feet total dynamic head (TDH) (total amount of pressure when sewage is flowing in the system). The pumps are served by a new 60-inch manifold that connects to a 48-inch force main. From the VPP, flows are pumped south, under the Marina del Rey channel, and then to the HTP, which is located just south of LAX in Playa del Rey. Because of the 60-foot elevational difference between Venice (low point) and Playa del Rey (high point), the VPP must continuously pump the flows in order to avoid sewage backups.

During dry-weather flows (no rain), two duty pumps generally pump an average of 20 mgd of sewage. During wet-weather flows (rain), depending on conditions, all five pumps may be needed simultaneously to convey sewage influent from the collection area to the HTP. This is because the system is not closed and can be affected by infiltration (i.e., from storm drains and groundwater). During certain years, flows during wet-weather conditions have reached 50 mgd. When operating simultaneously, the five pumps are capable of pumping some 14,000 gallons per minute.

Due to their continuous use, the pumps require regular maintenance and therefore need to be taken off-line to be serviced and repaired. The pumps have had several maintenance issues in the past. At times, two pumps have been out of service for extended periods during wet-weather flows. To provide the required capacity at the pumping plant during such events, the City rents portable pumps to supplement the existing pumps. However, pumps that are capable of handling solids are uncommon in the required sizes and difficult to rent. Therefore, the City incurs significant costs when additional pumps are needed. Furthermore, the portable aboveground pumps result in noise and odor impacts on the surrounding neighborhood when temporarily in operation. To provide for redundancy and ensure adequate pumping capacity when the pumps are temporarily out of service, the City needs a total of eight (i.e., three additional) pumps.

There have been several occasions, beginning in the 1990s and extending through the early 2000s, when influent flows to the VPP during periods of wet weather nearly exceeded the combined pumping capacity (90 mgd) of all five pumps while working simultaneously. This resulted in a near miss of sewage spill into the Grand Canal and Ballona Lagoon because the wet wells and pumps were almost entirely inundated by sewage. Exceeded sewer capacity would have required emergency discharges directly to the Grand Canal and Ballona Lagoon or overflows into the surrounding street network. Because of these conditions, the City of LABOE, began planning and designing projects that would upgrade and enhance the CIS and VPP. These projects include the VPP Manifold Replacement Project, which was completed in August 2015, the Venice Dual Force Main (VDFM) Project, construction of which will begin in late 2016, and the proposed VAPP project.

2.7 Project Overview

Implementation of the Proposed Project, which entails the construction of a new pumping plant adjacent to the existing VPP, would provide redundancy and ensure reliability for the sewer collection system. Project implementation would also allow the sewer system to accommodate sewage flows during extreme weather (e.g., El Niño) as well as sea-level rise, along with corresponding increases in groundwater levels that exacerbate infiltration conditions, both for the existing and planned conveyance system. The potential for near misses and/or catastrophic system failures would be significantly reduced with upgraded sewer system redundancy and reliability. As described below, a number of system improvements would be implemented both above and below ground, including a new electrical building, housing the control system and employee workstations; three new pumps and associated generator; connections to the VPP; and parking, public art, and green space. Combined, the five existing pumps at the VPP and the three new pumps would have a rated capacity of 87 mgd (i.e., five duty pumps and three standby). All pumps would have a similar capacity and be functionally equivalent.

2.8 Proposed Project

The Proposed Project would be built on three vacant lots with a total combined area of approximately 12,076 square feet. As shown in Figure 2-4, Site Plan, the Proposed Project would include a number of improvements:

- One building, two stories and approximately 32 feet in height, with a total of 2,500 square feet that will house the operational control center for the plant, related electrical equipment, and employee workstations;
- Three 18 mgd submersible pumps, constructed underground;
- Electrical equipment, utility connections, instrumentation and controls, transformers, and generators;
- A 17- by 17-foot submerged diversion structure on the existing CIS, the top of which would be below the lowest elevation of the Grand Canal and buried underneath it;
- Concrete wet well, influent piping and a sluice gate;
- A new 66-inch sewer to connect VAPP to the new diversion structure;
- Fencing with blinds and vegetation for screening the VAPP building;
- Parking – a total of eight parking spaces will be provided at 128 Hurricane Street to allow for employee, delivery/visitor, and public parking, including the replacement of coastal parking; and
- Landscaping and Open Space at 128 Hurricane Street.

2.8.1 Operational Requirements

The VPP and VAPP combined will have an ultimate peak flow capacity of 87 mgd, based on the ultimate wet-weather flows (10-year storm event). The City's peak wet-weather modeling results established this flow rate (*Development of a Conceptual Plan for an Auxiliary Pumping Facility Alternative for the Venice Pumping Plant* [Carollo 2014]). The basis of design for the VAPP is summarized as follows:

- Ultimate Peak Wet-Weather Flow: 87 mgd (design based on 10-year storm event)
- Ultimate Peak Dry-Weather Flow: 71 mgd
- Current Peak Wet-Weather Flow: 55 mgd (January 6, 2009)
- Current Peak Dry-Weather Flow: 36 mgd
- Minimum Low Dry-Weather flow: 15 mgd (design)

The VAPP will have three submersible pumps available to operate at all times with variable frequency drives (VFD) that have the ability to adjust motor speed to match discharge flows. Sufficient overlap of pump operating ranges will be provided so that each pump flow condition will allow for the most efficient pump operation.

The VPP and the VAPP will act as one large wet well connected via the influent sewer. They will operate independently however, with separate controls. The VAPP can be isolated from the influent sewer by a slide gate located at the entrance to the wet well. The VPP does not have the capabilities to be isolated and taken off-line and as such, for wet well maintenance, a temporary plug will be required at the upstream manhole. The control system will provide the ability to operate each pumping plant independently if one of the pumping plants needs to be taken off-line for maintenance. The ideal operations scenario for the VPP and VAPP will be to operate and maintain a constant water surface level using the VFDs and a set of pump operational parameters depending on the flow level.

2.8.2 Aboveground Facilities

The Proposed Project includes a two-story electrical and control building along the west side of Project Site, adjacent to Canal Court (see Figure 2-4, Site Plan) and associated employee and visitor/delivery parking for the new building located at 128 Hurricane Street. The building would be two stories, about 32 feet in height, 50 feet in length, and 2,500 square feet (both levels combined) in area. The building would include spaces for an electrical equipment room and a generator room on the first floor. In addition to a state-of-the-art control station, the second floor would include workstations for computer operators, a restroom, mechanical room, and server rooms. Heating, ventilation, and air-conditioning equipment for the electrical building would be located north of the building.

The preliminary building design includes perimeter walls constructed of reinforced concrete, with a cool roofing system (PVC membrane or similar) above the second level. Proposed finishes include architectural stamped concrete, reveals, and impressions; metal awnings over each of the exterior doors and sustainable roofing (Sika Décor or similar); and painted surfaces with colors that blend in with the surrounding neighborhood. Windows would be required for occupied spaces on the second level; all windows would be energy-efficient dual-glazed units. The exterior conceptual design would be enhanced to include architectural features that are in keeping with the architecture, massing, and materials that are currently present on the adjacent residential structures.

The VAPP electrical system would include a small diesel-fueled standby generator to provide power for critical loads in the event of a loss of power from the Los Angeles Department of Water and Power (LADWP) and the inability of existing VPP standby generators to provide power to the VAPP. The standby generator would be located in an enclosed room on the first floor; an intake and exhaust louver would provide the proper cooling for the generator. Because of the location of the electrical building within a residential neighborhood, acoustic louvers would also be installed. The VAPP generator would provide up to 24 kilowatts (kW) of power at 120/240 volts (V) for lighting,

Figure 2-4
Site Plan
Venice Auxiliary Pumping Plant Project

the Supervisory Control and Data Acquisition system, the security/access control system, and air conditioning for the VAPP control room. The VAPP generator would have an integral storage tank that would hold enough fuel for up to 8 hours of run time at full load.

2.8.3 Parking

Parking for the Proposed Project would be provided on the 128 Hurricane Street lot. There would be a total of eight parking spaces. Per the Venice Specific Plan and the Venice Local Coastal Program Land Use Plan, the Proposed Project would require at least five project-dedicated parking spaces, four for the project, and one for Beach Impact Zone parking. Existing on-street parking spaces along Hurricane Street on the south side of the new VAPP lot would be removed and replaced on the 128 Hurricane Street lot to be consistent with the California Coastal Act.

2.8.4 Public Art

This Proposed Project may include a public art installation on the 128 Hurricane Street lot. All City capital improvement projects whether funded by Council controlled or proprietary departments must comply with the City of Los Angeles Public Works Improvements Arts Program. The program was established to connect all City capital improvement projects with the opportunity to create art installed at facilities, to enhance amenities, assist with the restoration of historic features and provide community art services throughout the City. The program is managed by the Department of Cultural Affairs (DCA) and its General Manager. All public art projects are reviewed by the Public Art Committee and recommended for approval by the Cultural Affairs Commission.

2.8.5 Belowground Facilities and Diversion Structure within the Grand Canal

At the northeast corner of the Project Site, adjacent to the Esplanade, three 18 mgd submersible pumps and a valve and metering vault are proposed (see Figure 2-4, Site Plan). The three submersible pumps would withdraw sewage from a wet well through a new 66-inch sewer pipe and discharge into a common header that would serve both the VPP and VAPP. Each force main (48-inch and 54-inch) could then be isolated by ball valves that would be controlled at the VAPP. Under normal operation, the VAPP and VPP would operate as a single functional pump station, with their respective wet wells hydraulically linked through similar elevations and an even flow split. Access would be limited to the structure that would house the pumps and vault. Sealed hatches would provide access for maintenance and minimize odors.

As noted above, the existing 66-inch CIS sewer pipe that serves the VPP is located within the Grand Canal. To minimize disruptions to the VPP, a diversion structure would be constructed to allow flows to be diverted to the VAPP. The diversion structure would be below the grade of the Grand Canal, by approximately 18 feet, and would not protrude aboveground into the Canal and would be buried beneath it. The structure would allow flows to be diverted to either the VAPP or VPP. A gate would also be provided at the inlet of the VAPP to allow isolation for maintenance purposes.

Influent piping would be provided from the new diversion structure to the new wet well. The lined concrete cylinder pipe would be protected from corrosion caused by hydrogen sulfide. The VAPP piping would connect to the new VPP replacement manifold that was recently constructed in Hurricane Street with use of a 42-inch flange at its west end. From there, the piping would continue back to the new valve vault at the VAPP.

2.8.6 Odor Control

As noted above, the existing VPP is equipped with an exhaust fan that discharges vapors through an existing stack. The wet well and associated pumps are sealed and located underground. Field investigation of the ventilation fan shows that the flange that connects the fan to the dispersion stack is displaced, and odors can exit through the gap at the joint. To remedy this, the fan and flanges would be replaced with compatible equipment. In addition, a slide gate at the entrance to the VAPP wet well from the influent pipe would be installed to deter odors. Any odors in the CIS piping will be confined to that system and handled as they normally are at the VPP. When the VAPP is in operation, the head spaces of the wet wells will be linked by the 66-inch sewer, and the exhaust fan will be able to service the entire system. No additional odor control measures are anticipated.

During construction of the coffer dam within the Grand Canal, sediment that contains organic material would be extracted which could result in odors when removed from the ground if not properly handled. Once these materials are removed, they would be temporarily stored in Laydown Areas 1 and 3. Various odors may be emitted from the sediment piles during construction that may impact the sensitive receptors in the project area. However, best management practices will be used to address any potential odors.

2.8.7 Utilities and Services

For VAPP operation, electricity, potable water, and sewer service utilities would be required. Each of these is discussed in greater detail below.

2.8.7.1 Electricity and Standby Power

Because the VAPP would be working separate from, yet in conjunction with, the VPP, the electrical power supply to VAPP would be independent from the VPP. As such, the Proposed Project would require two additional 480 V services from LADWP, providing an added degree of reliability and avoiding dependence on existing VPP step-down transformers and switchgear for utility power. Two existing 34.5 kV primary circuits that serve the VPP would be used because of their proximity. A new 34.5 kV switching cabinet, two new 34.5 kV–480 V three-phase pad-mounted transformers, and two new exterior secondary (480 V) cable pull sections, all owned and maintained by LADWP, would be installed for the new services at the VAPP. The 480 V three-phase power would be accepted from the LADWP pad-mounted transformers, with a switchgear located inside the VAPP electrical building. A main-tie arrangement would be provided to utilize either transformer, if necessary, and fully power the VAPP. Each main breaker would have an LADWP meter for revenue accounting and a digital meter for local monitoring/connectivity to the control system. The VAPP switchgear would distribute 480 V to the VAPP pump motor controllers and a motor control center.

Standby power for VAPP pumping operations would be provided by existing VPP standby generators in addition to a new generator (previously described above). The existing VPP 480 V switchgear, which receives and manages VPP standby generator power, would be utilized to provide standby power to the VAPP electrical system. Two 480 V, 1,600-amp (A) power circuit breakers would be installed in the existing VPP switchgear and connected to the VAPP 480 V switchgear. Removal of two 1,200 A power circuit breakers from the existing VPP switchgear would be necessary to facilitate installation of the new 1,600 A power circuit breakers. These new 1,600 A power circuit breakers would be manually operated and normally closed.

2.8.7.2 Potable Water and Sanitary Sewer

Potable water would be provided for equipment wash down purposes and a restroom that would be located in the electrical building. Sanitary sewer service would be provided for wash down and lavatory water.

2.8.8 Landscaping and Drainage

Because a minimal amount of open area would be present at the VAPP site, landscaping would largely be limited to 0.75-inch gravel or crushed stone for erosion and dust control. Depending on space availability and infrastructure requirements, the planting of shrubbery and trees may also be possible. The specific locations and species would be evaluated and then included in a landscape plan that would be prepared during final design.

On the 128 Hurricane Street lot, following completion of project construction, the construction laydown site would be converted to a publicly accessible site with public art, parking, and green open space. The specific locations and species of plantings within the open green space would also be identified in a landscape plan that would be prepared during final design.

New stormwater drainage facilities associated with the Proposed Project would be constructed entirely within the Project Site. These may include storm drains, inlets, downspouts, catch basins, and overland sheet flow and low-impact development features.

2.8.9 Site Security

As with the existing VPP, the entire VAPP site would be secured with fencing and/or concrete walls. Signage at an access-controlled entry/exit gate would denote the area that is closed to the public. In addition, an access control and video surveillance system would be provided to protect operators while working between the two sites and provide remote monitoring. Perimeter security lighting would also be installed within the VAPP site. It is anticipated that nighttime lighting sources would face inside away from sensitive receptors and be similar to those on the adjacent VPP site. All lighting would adhere to applicable plans and ordinances.

2.8.10 On- and Off-site Circulation, Parking, and Pedestrian Access

Pacific Avenue, Hurricane Street, Via Dolce, and Marquesas Way will provide access to the Project Site, including construction Laydown Areas. Hurricane Street between Canal Court and Esplanade would be closed to public traffic during construction; however, these roadways would remain accessible during operation of the Proposed Project and preserve Coastal Access (see Figure 2-2, Project Location Map). Parking would be eliminated permanently but relocated to the 128 Hurricane Street lot. A total of eight parking spaces would be provided on the 128 Hurricane Street lot for employees and deliveries/visitors (five) and relocation of existing on-street parking spaces at the terminus of Hurricane Street (three).

Pedestrian access to the Esplanade and associated Grand Canal and Ballona Lagoon from Hurricane Street would be temporarily eliminated during construction (up to 2 years). However, alternative access to these areas would be available via existing routes along Canal Court and Galleon Street or Esplanade. During operation, pedestrian access would continue to be available from Hurricane Street, Canal Court, and the 128 Hurricane Street lot, and coastal access would be maintained.

2.8.11 Open Space

The Proposed Project would include Open Space, as required by the Venice Specific Plan and would be incorporated into the project design on the VAPP site and at the 128 Hurricane Street lot. Although the exact design of the Open Space has not been finalized, Figure 2-4, Site Plan contains a preliminary design. As currently envisioned, a total of 3,639 square feet of open space would be provided on the VAPP site and a total of 787 square feet would be provided for public use on the 128 Hurricane Street lot. Some type of public art may also be incorporated into the 128 Hurricane Street lot.

2.8.12 Operations and Maintenance

Once operational, the VAPP would augment the existing capacity of the VPP. However, the VAPP would also enhance capacity so that a combined ultimate peak flow of 87 mgd could be accommodated and processed through the VPP and VAPP. This capacity would be capable of accommodating wet-weather flows from a 10-year storm event. During operations, the Proposed Project would require two full-time employees (per shift) who would work three consecutive 8-hour shifts, 7 days per week.

Maintenance requirements for VAPP equipment are anticipated to be similar to those for VPP. The main focus would be the three submersible pumps, which would be accessed from hatches to the wet well. It is anticipated that each pump would need to be inspected annually. This would require short-term use of equipment and machinery over 2 or 3 days as well as construction workers to remove, inspect, and service the pumps. Additionally, in instances when pumps need to be removed for maintenance purposes, temporary, short-term closure of Hurricane Street east of Canal Court to Esplanade and fronting both VAPP and VPP may be required. As noted above, this temporary closure is anticipated to occur twice yearly for up to 2 weeks. Access to the diversion structure would be provided from a manhole that would connect it to the wet well. No access from the Grand Canal would be required during these regularly scheduled maintenance activities.

2.8.13 Construction

Construction of the Proposed Project is anticipated to begin in March 2018 and last approximately two years. Construction would begin with initial site preparation, which would enable machinery and equipment to access and work within the site. Once the site is prepared, construction phasing would involve six distinct stages in two separate areas, as outlined below and shown in Figure 2-2, Project Location Map, which shows the locations where access would be temporarily restricted to the public and the location of the three proposed laydown areas.

- Area 1 – Vacant lot at 128 Hurricane Street, immediately west of the VPP and adjacent to Ballona Lagoon. This site is approximately 4,345 square feet and would be used as a construction laydown area.
- Area 2 – Two vacant lots across from and east of the Grand Canal at Via Dolce. This site, accessed from Via Dolce, is approximately 6,150 square feet and could be used for materials and equipment storage.
- Area 3 – A vacant lot located at 9940 Jefferson Boulevard, Culver City will be used for soil stockpiling; the lot measures approximately 198,735 square feet.

Standard construction equipment would be used, including compactors, bulldozers, front loaders, trenchers, construction cranes, water trucks, dump trucks, and delivery trucks that would bring construction-related materials to the site. Construction access to the Project Site would be via Pacific Avenue, Hurricane Street, Via Dolce, and Marquesas Way. Construction workers would be required to park off-site and then travel to and from the site by shuttle. No construction worker or equipment parking would be allowed along Hurricane Street or on adjacent streets. Access to Laydown Area 3 in Culver City would be achieved via Hurricane Street, Pacific Avenue, Washington Boulevard, Lincoln Boulevard, and other streets such as Sepulveda Boulevard, and Jefferson Boulevard. The final haul route will be selected in consultation with the Los Angeles Department of Transportation (LADOT) and the City of Culver City.

During construction, some perimeter lighting may be required, both on the Project Site and in Laydown Areas 1 and 2, for security purposes. Lighting would, however, be directed on-site and away from sensitive receptors (residences and the Grand Canal) to minimize any spillover effects. Security fencing would be erected around all laydown areas prior to construction activities.

2.8.13.1 Stage 1

Prior to initiating construction, security fencing would be erected around Laydown Area 2 (APNs 4225-013-153 and 4225-013-904), across from and east of the Grand Canal, and at Laydown Area 3, in Culver City (APN 4296-001-270). The Project Site and Laydown Area 1 (APN 4225-010-016) are currently fenced. A portion of Hurricane Street and Canal Court would be temporarily closed (see Figure 2-2, Project Location Map). Shoring would be installed around the Project Site, after which excavation to a depth of approximately 25 feet and dewatering of the site would occur. At this stage of construction, pedestrian access along the Esplanade, Ballona Lagoon, and the Grand Canal would be maintained at Canal Court. However, pedestrian access to the Grand Canal from Hurricane Street would be temporarily eliminated; pedestrians would be diverted to Galleon Street to the north (see Figure 2-2, Project Location Map).

2.8.13.2 Stage 2

Upon completion of excavation at the VAPP site, the bottom of the excavated site would be sealed and prepared for the above - and below - ground structure and related facilities. Preliminary earthwork plans indicate that the Proposed Project would require approximately 10,000 cubic yards of soil to be excavated, of which approximately 2,300 cubic yards would be stockpiled at Laydown Area 1. The remaining 7,700 cubic yards of soil would be exported off-site and stockpiled at Laydown Area 3, resulting in a total of 2,970 total one-way truck trips. Laydown Area 2 (across Grand Canal), given the slope and access constraints, may be used only as needed for equipment and materials storage. Laydown Area 1 will be the primary laydown area and storage site. For backfill at the VAPP, a total of 2,300 cubic yards of soil would be utilized from Laydown Area 1 and 3,850 cubic yards from Laydown Area 3. The total truck trips associated with transporting the 3,850 cubic yards of soil from Laydown Area 3 to the VAPP would be 1,486 total one-way truck trips. Once the VAPP is completed, the remaining total of 3,850 cubic yards of soil stockpiled at Laydown Area 3 would be disposed of at the Sunshine Canyon Landfill or similar facility, resulting in a total of 1,486 total one-way truck trips. The estimates presented here of total truck trips include an allowance of 35% for soil expansion and less-than-full loads, and assume that soil is transported in trucks with a capacity of seven cubic yards. Water pumped from the site would be disposed of in a manner consistent with Regional Water Quality Control Board regulations.

Proposed grading for the site would slope away from the electrical building and pumping plant for a minimum of 5 feet and then be directed via swales or similar surface features toward the east property boundary. This would follow the existing drainage pattern for the majority of the site.

2.8.13.3 Stage 3

Construction of the underground facilities associated with the proposed VAPP, including the three new pumps, the wet well, valve vault, meter vault, and piping, would occur during this stage. These facilities would be constructed at a maximum depth of approximately 25 feet below ground. Upon installation of the underground features, the site would be backfilled and compacted with the existing stockpiled soil contained within Laydown Area 1.

2.8.13.4 Stage 4

Within the Grand Canal, a new sewer diversion structure, approximately 23 by 95 feet, would be installed at a depth of approximately 18 feet below ground at the canal and then sealed. To facilitate the installation of the diversion structure, a temporary coffer dam would be installed. Water flowing in the Grand Canal would be diverted around the cofferdam structure so that excavation could occur without inundation. With excavation completed, the diversion structure would be constructed in place, and then sealing would occur. Excavated materials would be hauled from the site and stockpiled at either Laydown Area 1 or Laydown Area 3 or transported to an approved area landfill; upon completing of installation and sealing, The Grand Canal would be backfilled using the stockpiled excavated material and the coffer dam removed. Ultimately, the diversion structure would be entirely underneath the Grand Canal. Construction of the cofferdam, placement of the diversion structure, and backfill and soil compaction within the Grand Canal would last approximately 4 to 6 months. During that time, the Esplanade on the west side of the Grand Canal would be temporarily closed between the northern boundary of the Project Site and approximately 95 feet south of the existing VPP (see Figure 2-2, Project Location Map).

2.8.13.5 Stage 5

During this stage a modular diversion structure will be installed over the CIS, feeding the new wet well to divert sewage flows. The pipe would then be connected, and a seal would be inserted into the shell. Backfill and soil compaction would be completed, and the Grand Canal channel bottom would be restored to its original elevation.

2.8.13.6 Stage 6

This final stage would involve sealing the diversion structure, removing all shoring steel, and allowing flows to resume to pre-construction conditions within the Grand Canal. The Esplanade would be re-opened to pedestrian access on the west side of the Grand Canal. Construction of surface improvements at the Project Site would then occur. This would include constructing an approximately 32-foot-high electrical building, installing two new 480 V LADWP transformers, and providing public access and landscaping improvements.

2.9 Relationship to Other Projects

The projects noted below, in combination with the proposed VAPP and VPP, will provide system reliability and redundancy and allow influent flows from the existing 66-inch CIS pipe to be bypassed to the VDFM during extreme weather events or an unforeseen emergency.

2.9.1 Venice Dual Force Main

The VDFM is a new 54-inch-diameter force main in the vicinity of the VPP and proposed VAPP. The new pipeline alignment will cross the Grand Canal from the VPP, extend northerly along Hurricane Street to Marquesas Way, then continue southerly along Via Marina before crossing the Marina Del Rey and Ballona Creek channels to the CIS Diversion Structure on Vista del Mar near Waterview Street. The new force main will operate as a parallel system in conjunction with the existing 48-inch force main to meet the peak wet-weather flow demands experienced at the VPP and add operational flexibility and reliability. The City anticipates finishing construction on the VDFM by 2019.

2.9.2 VPP Manifold Replacement Project

The VPP Manifold Replacement Project was recently completed (August 2015) within Hurricane Street. That project consisted of removing the existing manifold structure located within Hurricane Street, between Canal Court and the Esplanade, and installing a new 60-inch steel manifold with connections to the VPP, the existing 48-inch force main, and stub-outs at both ends for connection to the future 54-inch VDFM and planned VAPP.

2.9.3 Venice Pumping Plant Generator Replacement

The project includes demolition of the existing diesel-fueled standby engine/generators and procurement/installation of two new 750- kW generators and one new 1,500 kW generator with ancillary controllers, transfer switches, exhaust and cooling systems, and fluid storage.

2.10 Responsible Agencies and Project Approvals

Table 2-1, Required Permits for Venice Auxiliary Pumping Plant Project, lists the anticipated permits required for the Proposed Project. The need for these permits will be verified through agency correspondence during the CEQA process.

Table 2-1. Required Permits for Venice Auxiliary Pumping Plant Project

Agency	Permit/Requirement	Issue
Local		
City of Los Angeles Department of Public Works	Local Coastal Development Permit	Coastal access, construction within coastal zone, habitat disturbance, parking and traffic during construction
City of Los Angeles Planning Department	Specific Plan Project Permit Compliance	Compliance with the Venice Coastal Specific Plan. Also consistency with the Venice Local Coastal Program Land Use Plan
City of Los Angeles Planning Department	Public Benefits Project Permit	Section 14 of the Los Angeles Municipal Code. Public Benefit permit with Alternative Compliance for Public Facilities and Park/Recreation uses
City of Los Angeles Planning Department	Los Angeles Municipal Code Adjustment for Yards	Relief for encroachment more than 6 feet into the rear yard
City of Los Angeles Planning Department	Conditional Use Permit for Parking	Relief for encroachment more than 6 feet into the rear yard
Los Angeles County Department of Public Works/Department of Beaches and Harbors	Encroachment permit	Access and use of parcel for Laydown Area 2
City of Culver City, Planning Department	Temporary Use Permit	Temporary stockpile of soil (up to 7,700 cubic yards) for Laydown Area 3
Regional		
Los Angeles Regional Water Quality Control Board (RWQCB)	National Pollutant Discharge Elimination System (NPDES) Construction Stormwater Pollution Prevention Plan permit	Water quality and placement of discharges associated with dewatering activities; no permit required for discharges to sewer (general permit saves time with RWQCB)
RWQCB	401C section certification	State water quality certification prior to an issuance of U.S. Army Corps of Engineers (USACE) nationwide permit
South Coast Air Quality Management District	Permit to construct and operate	Air quality, additional portable generator(s), and any modifications to odor dispersion stack
State		
California Coastal Commission	State Coastal Development Permit	Coastal access, construction within coastal zone, habitat disturbance, parking and traffic during construction

Agency	Permit/Requirement	Issue
California Department of Conservation, Division of Oil, Gas, and Geothermal Resources	A construction notification form should be submitted to the division prior to any activity	Project is within boundaries of the Playa del Rey oil field, which contains numerous plugged and abandoned oil wells
State of California Department of Health Services	Project review for compliance with Title 22, Section 64630 (conducted through County Environmental Services Division)	Separation of water and sewer mains
California Office of Historic Preservation	Consultation	Historic status of Grand Canal
Federal		
USACE	Section 10 permit	Pipeline construction under navigable waters
USACE	Section 404	Could fall under Nationwide Permit NWP 12, Utility Line Activities, and require Pre-Construction Notification (PCN)
National Marine Fisheries Service	Consultation notification	Impacts on aquatic and marine life
U.S. Fish and Wildlife Service	Notification through Section 10 process	Impacts on habitat (i.e., least tern)

2.11 Project Schedule

Construction is anticipated to begin in March 2018 and last approximately two years. To minimize impacts on the surrounding community, streamline construction activities, and minimize overall project cost, the City is planning to schedule construction of the VAPP immediately after completion of the VDFM, which is planned to start construction in winter 2016 and end in winter 2019.

Chapter 3
Environmental Impact Analysis

3.1 Aesthetics

This section addresses the potential for the Venice Auxiliary Pumping Plant (VAPP or Proposed Project) to result in impacts on aesthetic resources. The purpose of this analysis is to establish a baseline for evaluating visual resources in the project area and determine if a significant change in the visual environment would occur as a result of the Proposed Project. Project components reviewed in this section include all proposed visible features as well as construction techniques. The analysis discusses the potential for the Proposed Project to result in construction and operational impacts. The Proposed Project is evaluated with respect to a viewer's expected sensitivity and expectations and reviewed for consistency with applicable planning policies. Levels of impact are determined in accordance with the guidelines provided in the *L.A. CEQA Thresholds Guide*. Mitigation measures, where applicable, are recommended to avoid or minimize significant visual impacts. As noted in the analysis below, direct and indirect impacts associated with aesthetics during construction and operation would be less than significant. However, as described in Section 3.1.4, in an effort to reduce perceived effects as much as practicable, several mitigation measures have been recommended for incorporation into the project.

The Proposed Project would include construction of a pumping facility on a vacant site at the northeast corner of Hurricane Street and Canal Court, adjacent to the existing Venice Pumping Plant (VPP). The Project Site comprises three undeveloped residential lots and are described in Chapter 2, Project Description. The Project Site is surrounded on the north and west by residential buildings and on the east by the Venice Grand Canal and residential buildings. Ballona Lagoon is south of the Project Site.

3.1.1 Regulatory Setting

This section describes existing regulations that are applicable to the Proposed Project related to aesthetics and visual character, including the California Scenic Highways Program, California Coastal Act, Venice Community Plan, Venice Coastal Zone Specific Plan, Venice Local Coastal Program Land Use Plan, Los Angeles Municipal Code, Citywide General Plan Framework Element, City of Los Angeles Walkability Checklist, Citywide Design Guidelines, and the Public Art, Architecture, Landscape, and Urban Design Review Guidelines.

3.1.1.1 Federal

There are no federal regulations pertaining to aesthetics and visual resources that are applicable to the Proposed Project.

3.1.1.2 State

California Scenic Highways Program

The California Department of Transportation (Caltrans) established and implemented the California Scenic Highway Program to protect and enhance the natural scenic beauty of California highways and adjacent corridors through special conservation treatment (Caltrans 2008).

Caltrans defines a State Scenic Highway as any freeway, highway, road, or other public right-of-way that "traverses an area of outstanding scenic quality, containing striking views, flora, geology, and other unique natural attributes" (Caltrans 2008).

Once a highway has been designated as a state or national scenic highway, or a scenic corridor, special consideration must be given whenever a project proposes to develop the surrounding area.

California Coastal Act

The California Coastal Act of 1976 was adopted after state voters approved Proposition 20 in 1972. A key factor that led to the passage of this landmark legislation was the visible deterioration of the coastal environment as well as development pressures from a growing population (California Coastal Act 2014).

Section 30251 of the act is pertinent to visual resources preservation, stating:

> The scenic and visual qualities of coastal areas shall be considered and protected as a resource of public importance. Permitted development shall be sited and designed to protect views to and along the ocean and scenic coastal areas and, where feasible, to restore and enhance visual quality in visually degraded areas. New development in highly scenic areas such as those designated in the California Coastline Preservation and Recreation Plan prepared by the Department of Parks and Recreation and by local government shall be subordinate to the character of its setting.

Section 30253 states, in part, that new development within the Coastal Zone shall

> …where appropriate, protect special communities and neighborhoods that, because of their unique characteristics, are popular visitor destination points for recreational uses.

3.1.1.3 Local

Urban Design Studio

The function of the Department of City Planning's (DCP's) Urban Design Studio (UDS) is to offer a progressive Urban Planning approach that integrates required design guidelines and design standards from applicable land use and planning policies into the design of projects. The UDS offers guidance in the form of consultations with staff that combines principles of good urban design through innovative policies to help projects comply the City of Los Angeles' Planning and Zoning Code. The VAPP has several code based design guidelines and standards derived from the following policies that shaped the design and layout of the Project Site.

Los Angeles Municipal Code

The Los Angeles Municipal Code (LAMC) sets forth regulations and standards regarding the allowable types, densities, heights, and designs for new development projects. In particular, Chapter 1 of the LAMC, General Provisions and Zoning, provides development standards for the various zoning districts in the City of Los Angeles. In addition, the LAMC also sets forth the following specific regulations regarding lighting:

> **Chapter 1, Article 2, Section 12.21, General Provisions, Paragraph A, Section 5, Part (k),** restricts light spill onto adjacent properties and provides minimum luminance levels for safety within and around parking facilities.

Chapter 1, Article 7, Section 17.08 C, states that plans for street lighting shall be submitted to and approved by the Bureau of Street Lighting for subdivision maps.

Chapter 9, Article 3, Section 93.0117, states that no exterior light source may cause more than two foot-candles of lighting intensity or generate direct glare onto exterior glazed windows or glass doors; elevated habitable porch, deck, or balcony; or any ground surface intended for uses such as recreation, barbecue or lawn areas or any other property containing a residential unit or units.

Chapter 1, Article 2, Section 12.09.5, regulates the RW2-1 Zone – Rear yards and states that There shall be a rear yard of not less than 15 feet in depth. Notwithstanding any provisions of this article to the contrary, the rear lot line is that line opposite and most distant from the lot line separating the narrowest canal frontage of the lot from the navigable public canal or waterway.

Venice Community Plan

The Venice Community Plan is one of 35 community plans that make up the Land Use Element of the City of Los Angeles General Plan. As part of the General Plan, the Venice Community Plan, among other purposes, guides development within the area to create a healthful and pleasant environment. Chapter III, Land Use Policies and Programs, is the Land Use Element of the General Plan for the community plan area, which covers approximately 2,061 acres and is located in the western portion of Los Angeles. Chapter III includes a number of objectives and policies that address the visual aspects of new development, including protecting views of wetlands, bluffs, and distinctive visual resources from surrounding public streets and Open Space areas; using landscaping and plant materials to screen and soften visually obtrusive elements; and designing public works improvements with use of the least environmentally disturbing methods. Chapter V, Urban Design, of the community plan provides broad urban design objectives for each district in the area. The design policies and guidelines presented in Chapter V complement existing regulations contained in the adopted specific plans within the community plan area. These design policies and standards ensure that residential, commercial, and industrial projects as well as public spaces and rights-of-way incorporate specific elements of good design. The intent is to promote a stable and aesthetically pleasant environment. In commercial corridors, the emphasis is on the provision and maintenance of the visual continuity of streetscapes and the creation of an environment that encourages both pedestrian and economic activity. In multi-family residential areas, the emphasis is on the promotion of architectural design that enhances the appearance of structures and contributes to the quality of life, living conditions, and neighborhood pride of the residents. In industrial areas, the intent is to improve compatibility between industrial uses and non-industrial uses and encourage quality industrial development.

Venice Coastal Zone Specific Plan

One of the purposes of the Venice Coastal Zone Specific Plan (Venice Specific Plan) is to protect, maintain, enhance, and where feasible, restore the overall visual quality of views to and along the ocean and scenic coastal areas and their natural and man-made resources. It also regulates all aspects of development, including use, height, density, setback, buffer zone, and other factors so that it is compatible with the character of the existing community. It provides for the consideration of aesthetics and scenic preservation and enhancement; and protects environmentally sensitive areas.

The Venice Specific Plan has development regulations that include development standards for each subarea of Venice. The overall project area is located in the Ballona Lagoon West Bank Subarea and Laydown Area 2 is located in the Ballona Lagoon (Grand Canal) East Bank Subarea. The 128 Hurricane St site, which is both Laydown Area 1 and part of the Project Site is located in the Ballona Lagoon West Bank Subarea. As noted in the Venice Specific Plan, whenever the provisions of this Specific Plan differ from the provisions in Chapter 1 of the LAMC, (with regard to use, density, lot area, floor area ratio, building or structure heights, setbacks, yards, buffers, parking, drainage, fences, landscaping, design standards, light, trash, and signage), the provisions of the Venice Specific Plan will supersede the other regulations. Similarly, whenever the Venice Specific Plan is silent, the regulations of the LAMC will apply. It should be noted that although the Venice Specific Plan has been adopted by the Los Angeles City Council, it has not been certified as the Land Implementation Plan portion of the Venice LCP by the California Coastal Commission.

Venice Local Coastal Program Land Use Plan

The Venice Local Coastal Program Land Use Plan (Venice LCP LUP) was prepared for development to comply with the California Coastal Act of 1976 within the Venice Coastal Zone. The Venice LCP LUP was established as the Land Use Plan of the Venice LCP, intended to be used to plan for the preservation and enhancement of its coastal environment. The Venice LCP LUP contains information of the kinds, location, and intensity of land uses, the applicable resource protection, development policies and where applicable, a listing of implementation policies. It also addresses issues related to coastal development and design and seeks to develop facilities that will serve the needs of coastal visitors and City residents as well as preserve and enhance coastal overviews, key viewpoint areas, and Open Space. The Venice LCP LUP was certified by the California Coastal Commission. The Venice LCP was not wholly certified, therefore this LUP is only used on a local level and entitled through either a Venice Coastal Development Permit or a Venice Specific Plan Project Permit Compliance Review.

City of Los Angeles Walkability Checklist

The 2008 Walkability Checklist for Entitlement Review was developed by the City DCP's UDS to encourage the planning staff, project proponents, and community stakeholders to pursue high-quality urban designs that provide enhanced pedestrian movement, access, comfort, and safety, both in the public right-of-way and on private properties. It specifies urban design guidelines that are generally applicable to all projects that require discretionary approval for new construction. The walkability checklist consists of objectives, goals, and implementation strategies regarding various design elements, which are intended to improve the pedestrian environment, protect neighborhood character, and promote high-quality urban form. Topics such as sidewalks, crosswalks/street crossings, on-street parking, utilities, building orientation, off-street parking and driveways, on-site landscaping, building façades, and building signage and lighting are addressed and should be considered in the design of a project.

Citywide General Plan Framework Element

The 2009 City of Los Angeles General Plan Framework Element provides a series of goals, policies, and objectives that pertain to urban design topics throughout the City of Los Angeles. With respect to the evaluation of aesthetics and views (i.e., the identification and evaluation of key visual resources and a determination as to the degree of visual impact that would be attributable to the project), the Framework Element's Urban Form and Neighborhood Design chapter establishes the goal of creating a livable city (i.e., a city with strong neighborhoods, walkability, a network of

attractive public spaces, affordability, and regional connections) for existing and future residents with interconnected, diverse neighborhoods (Goal 5A). Also within the Framework Element, the Open Space and Conservation chapter calls for the use of Open Space to enhance community and neighborhood character (Objective 6.2). The policies in this chapter recognize that there are communities where Open Space and recreational resources are currently in short supply and, therefore, suggests that pedestrian-oriented streets and small parks, where feasible, might serve as important resources for meeting the Open Space and recreational needs of residents (Policy 6.2.1).

Citywide Design Guidelines

The 2011 Citywide Design Guidelines were adopted by the City Planning Commission for use in reviewing applications for commercial, multi-family, mixed use, and industrial projects. The Citywide Design Guidelines are intended to implement the 10 Urban Design Principles of the City's Framework Element. The principles address mobility and transit access in the public right-of-way, green streets, neighborhood character, and improved equity and opportunity. These principles are a statement of the City's vision for the future of Los Angeles. They provide guidance for new development and encourage projects to complement existing urban forms in order to enhance the built environment in Los Angeles. The intended purpose of one principle is to develop inviting and accessible transit areas, which would be done by augmenting the streetscape environment with pedestrian amenities and reducing visual clutter.

Residential Citywide Design Guidelines

The Proposed Project is located within a single and multi-family residential area. As such, the Residential Citywide Design Guidelines (Residential Guidelines), which address multi-family residential/commercial mixed-use standards are the most appropriate and applicable guidelines. As noted in the Residential Guidelines, multi-family development in the City of Los Angeles varies across a wide spectrum of typologies, from low-density small lot subdivisions in suburban areas to high-density, mixed-use buildings in urban regional centers. Each typology presents unique challenges and opportunities. The Residential Guidelines are intended to address some of the most common, overarching challenges in designing multi-family developments encountered across the City. The prime areas of opportunity for attaining high quality design in multi-family and mixed-use projects include: maximizing sustainability in multi-family developments, establishing height and massing transitions from multi-family uses to commercial uses or less dense single-family residential; considering the pedestrian as the cornerstone of design over automobilecentric design; establishing landscaping and Open Space as essential design concepts from the outset of a project; and highlighting the role that quality building design can play in creating visually interesting and attractive multifamily buildings by contributing to existing neighborhood character and creating a "sense of place." The Residential Guidelines are intended for developers and architects as well as for advisory and decision-making bodies when evaluating a project.[1]

3.1.1.4 City of Los Angeles Administrative Code

The City of Los Angeles Administrative Code is used to assist City offices, departments, and other governmental agencies with their functions, and serves as the official source for information about ordinances enacted by the City of Los Angeles that regulate administrative processes.

Section 19.85 Public Works Improvements Arts Program - Public Art, Architecture, Landscape, and Urban Design Review Guidelines

The mayor-appointed Cultural Affairs Commission serves as an advisory body to the City's Cultural Affairs Department. The Cultural Affairs Commission approves the design of structures to be built on or over City property, or directly affecting public land or rights-of-way, and reviews and accepts works of public art proposed for acquisition by the City. The Cultural Affairs Commission exercises its discretion in accordance with the June 2008 Public Art, Architecture, Landscape, and Urban Design Review Guidelines. Projects submitted for review are subject to one of four guideline categories (public art, architecture, landscape architecture, or urban design), but it is acknowledged that all the guidelines are mutually supportive and should be considered together in the design of any development within or affecting the public realm. The issues addressed within each guideline category are outlined below.

Urban Design: Critical assessment of place, incremental development of a vibrant and hospitable public realm, pedestrian primacy, street envelope, building massing and site disposition, city lighting and streetscape amenities, new media, and mandatory preliminary early review.

Landscape: Natural systems, urban plant ecology, Open Space networks and corridors, variety of gathering spaces, site boundaries, new media, and mandatory preliminary early review.

Architecture: Encourage evocative design, ensure public realm improvement and activity, design buildings with ample Open Space and landscape, establish pedestrian-friendly site circulation, enhance defensible perimeters, provide façade interest, consider public lighting opportunities, promote sustainability, integrate the public art component early on, incorporate high-quality signage, wayfinding and graphic components, and encourage and provide preliminary early review.

Public Art: Artist-focused, expansive selection process; distinguish public artist selection from traditional design procurement; art panel qualifications; develop and expand the public artist pool; early artist selection; art and architecture process integration; artist independence; art maintenance; temporary public art projects; media and advanced technologies; multiple sites and portable art; and articulation of artistic intent.

3.1.2 Environmental Setting

The visual setting for the Proposed Project is defined below in terms of (a) visual character and quality within the larger community and throughout the study area; (b) scenic resources, scenic vistas, scenic corridors, and other visual resources within the larger community and throughout the study area; and (c) viewer groups potentially affected by the Proposed Project.

3.1.2.1 Defining Quality and Character of Visual Resources

Visual Character. The visual character of a view is described by the topography, land uses, scale, form, and natural resources in the view. Visual character is based on defined attributes such as physical traits—including form, color, line and texture (pattern elements)—as well as pattern character traits and the dominance, scale, and diversity or continuity of visual elements.

Visual Quality. Visual quality is based, in part, on the viewer's values and notions about what constitutes a quality setting. The three criteria that are used to define visual quality are listed below.

- *Vividness* is the visual power or memorability of landscape components as they combine in distinctive visual patterns.
- *Intactness* is the visual integrity of the natural and human-built landscape and its freedom from encroaching elements. It can be present in well-kept urban and rural landscapes as well as in natural settings.
- *Unity* is the visual coherence and compositional harmony of the landscape considered as a whole. It frequently attests to the careful design of individual human-made components in the landscape.

As a general rule, high-quality views are found to have topographic relief, a variety of vegetation, rich colors, impressive scenery, and unique natural and/or built features. Medium-quality views have interesting but minor landforms, some variety in vegetation and color, and/or moderate scenery. Low-quality views contain uninteresting features, little variety in vegetation and color, uninteresting scenery, and/or common elements.

Visual Character and Quality of the Venice Community

The community of Venice is home to approximately 45,000 residents, and the Venice Community Plan Area includes an estimated 2,061 acres of land (City of Los Angeles 2009). Located in the western portion of Los Angeles, the community includes Venice Beach and the Venice Boardwalk, which stretch from Marina Court on the north to Yawl Street on the south. The community is generally bounded on the north by Marine Court and Dewey Street (adjoining the city of Santa Monica). It extends in an irregular fashion from the Pacific Ocean eastward to Walgrove Avenue, Beethoven Street, and Del Rey Avenue, bordering the Palms-Mar Vista-Del Rey Community Plan Area, parts of Culver City, and Los Angeles County land in Marina Del Rey. The coastline extends to the northern and southern limits of Venice, and the beach is used as a regional recreational resource.

Elements of urban design range from beach foregrounds and other natural landscapes to built structures and associated landscaped areas. Much of the area is developed with a variety of land uses that are typical of beach communities. The predominant land use in the community is residential. The majority of the multi-family development is medium and high medium density and located west of Lincoln Boulevard, extending to the coastline and southward from Washington Boulevard within the Marina Peninsula. Approximately 7 percent of the land is designated for commercial uses (City of Los Angeles 2009). The majority of commercial facilities are small scale in character and serve the local population. A more intense commercial area is located on the western edge of the community, adjoining Lincoln Boulevard, and within the Oxford Triangle. This area contains movie theaters, a large hotel, and a variety of restaurants and other retail uses. The remainder of the commercial uses are generally located at street intersections (e.g., around the Windward Circle) or along major arterials such as Lincoln Boulevard, which is an auto-oriented commercial strip. Of the community's total area, approximately 3 percent is designated for manufacturing and industrial uses. Other concentrations of designated industrial and light manufacturing uses are found along Main Street, from Abbot Kinney Boulevard to Dewey and Navy Streets.

The ESHAs in the Venice Coastal Zone include Ballona Lagoon and Grand Canal south of Washington Boulevard, the Venice Canals north of Washington Boulevard, habitat buffer areas on the east and west banks of Ballona Lagoon, and the California least tern nesting areas, as identified on the ESHA

map in the Venice LCP LUP Land Use Plan (City of Los Angeles 2015). The Venice Canals, along with the adjacent Ballona Lagoon, support some of the last remaining pockets of coastal wetland habitat in Los Angeles County. The Venice Canals are part of the Ballona Lagoon sea water system and connected with Ballona Lagoon via Grand Canal. Ballona Lagoon is an easily accessible natural area of estuarine and intertidal habitat. The lagoon is also rich in invertebrate and fish species, some of which are easily observable from the shore. Mudflats in Ballona Lagoon are especially important to shorebirds and waterfowl, which forage there in the fall and winter.

Visual character throughout the community of Venice varies by location and the relative position of the viewer. Visual quality in the community of Venice ranges from low to high quality, depending on the presence of visual resources and the distance, speed, and angle of the viewer, amongst other variables. As typified by the key views shown in Figures 3.1-2A and 3.1-3A, views throughout the project area are mostly medium-quality views of minor landforms, with some variety in vegetation and color and/or moderate overall scenery. The views captured in the selected key views and in viewsheds, as well as lines of sight throughout the immediate project vicinity, particularly those where Ballona Lagoon/Grand Canal (the primary visual resources in the project area) form a large portion of the foreground or middleground, have moderate intactness. They combine fairly well-kept urban features and natural settings, are somewhat free from encroaching elements (i.e., lampposts, etc.), and, thus, maintain an overall moderate level of visual integrity. The same views are moderately vivid; the juxtaposition of water, landscape features, and surrounding man-made elements, such as residential buildings, form partially distinctive and memorable visual patterns. As such, views throughout the project area are also fairly unified, given the visual coherence and compositional harmony of the human-built components and natural features present in the visual setting. For the highest quality views in the immediate project vicinity, Ballona Lagoon/Grand Canal and associated landscape features dominate the viewshed; manmade features and street trees create visual diversity and form a somewhat continuous horizontal line pattern that provides a mostly residential backdrop for the visual setting. The existing VPP is visible throughout the immediate project vicinity as well, where its approximately 50-foot-tall stack serves as a prominent visual feature. The stack could constrain sightlines to other visual resources throughout the project area, depending on the location and angle of the viewer. Viewers with higher exposure and sensitivity to the project area would be accustomed to the vertical presence of the VPP's central stack and other man-made features. Views found throughout the project area are encapsulated in Key Views 1 and 2 (shown below). They form a fairly colorful ocular palette, contain a range of visual textures, and provide moderate scenic relief to viewer groups. As such, views throughout the project area are mostly medium quality.

Scenic Resources, Scenic Vistas, Scenic Corridors, and Other Visual Resources

SR-2, the only official State Scenic Highway (as defined by Caltrans) in Los Angeles County, is located approximately 33 miles northeast of the community of Venice. A segment of SR-1, also known as PCH, is designated as an eligible State Scenic Highway; a portion of SR-1 traverses the community of Venice (Caltrans 2011). The southern terminus of the eligible portion is located at the intersection of SR-1 (known as Lincoln Boulevard at this intersection) and Venice Boulevard, which is approximately 2 miles northeast of the Project Site. Other Designated Scenic Highways in the project area, as inventoried in the Mobility Plan 2035, include Culver Boulevard and Vista del Mar. Culver Boulevard, between Vista del Mar and the Ballona Creek, features views of the Ocean and Marina, as well as the Ballona Wetlands (depending on the position and angle of the viewer). Vista Del Mar, between Culver Boulevard and Imperial Highway, features sand dune and ocean views (depending

on the position and angle of the viewer). Culver Boulevard and Vista del Mar are approximately 1.4 miles south of the Proposed Project, on the south side of Marina del Rey and the Ballona Creek.

The Venice Local Coastal Program Land Use Plan designates special marine and land habitat areas, wetlands, lagoons, and estuaries within the local Coastal Zone that are of vital interest and sensitivity. The scenic and visual qualities of these areas and other coastal areas are considered resources of public importance. Ballona Lagoon/Grand Canal and associated waterways are zoned as Open Space (OS). This designation serves to protect recreational, residential, and scenic uses of the area while providing for other uses that would benefit the public without significant impairment of the recreational and residential uses. Standards, regulations, and development guidelines provided in applicable plans regulating development in the study area determine the height limits, setbacks, and the other design criteria necessary to ensure the appropriate scale of development and protect public views. The vacant lot proposed for construction of the VAPP and the site where the existing VPP is located are designated as Lots Fronting ESHAs. Ballona Lagoon and Grand Canal are the ESHAs; the lots are located just east of the Habitat Protection Buffer Strip, which lines the east and west sides of Ballona Lagoon from just south of Hurricane Street and west of the Project Site to its southern terminus at Via Marina.

No other officially designated scenic resources, vistas, or corridors have been identified within the immediate project vicinity. The primary visual resources throughout the project area are Ballona Lagoon and Grand Canal. Secondary visual resources include their associated landscape features, biological habitat areas, and street trees.

3.1.3 Environmental Impact Analysis

The discussion below identifies potential project impacts and the measures that would be required to mitigate impacts that are found to be potentially significant.

3.1.3.1 Methodology

This analysis generally follows the methodology outlined in the *Visual Impact Assessment for Highway Projects* (Federal Highway Administration [FHWA] 2015), which is considered an accepted standard for evaluating the visual effects associated with highway, railroad, and a wide range of nontransportation-related projects.

Determining Quality and Character of Visual Resources

The assessment of visual character is based on defined attributes such as physical traits—including form, color, line, and texture (pattern elements)—as well as pattern character traits and the dominance, scale, and diversity or continuity of visual elements.

Determining the quality of a view is based, in part, on the viewer's values and notions about what constitutes a quality setting. In an effort to establish an objective framework, this analysis applies the evaluative criteria (i.e., vividness, intactness, and unity, as described in Section 3.1.2.1) and qualitative rankings (low, medium, and high, also described in Section 3.1.2.1) presented in the FHWA guidelines. This method should correlate with public judgments of visual quality well enough to predict those judgments and can also help identify specific methods for mitigating each impact that may occur as a result of a project.

Viewer Groups and Assessing Viewer Response

Viewer response comprises two elements: *viewer sensitivity* and *viewer exposure*. *Viewer sensitivity* is both the viewer's concern for scenic quality and the viewer's response to change in the visual resources that make up the view. *Viewer exposure* is a measurement of the number of viewers exposed to the resource change as well as the frequency of the viewing opportunity, type of viewer activity, duration of the view, speed at which the viewer moves, and position of the viewer.

There are two basic groups of viewers present in the project area, as well as several sub-groups: (1) viewers associated with specific buildings (e.g., residents) and (2) mobile viewers (e.g., commuting motorists, pedestrians, sightseers). Residential viewers typically have the highest level of sensitivity to visual quality and changes to visual quality because of their familiarity with the view over a period of time, investment in the area, and sense of ownership of the view. Other viewers, with exceptions, usually have low or average sensitivity to visual quality or change. These include people on the local roadway system, such as commuting motorists and pedestrians. If they are traveling simply to get from one place to another for work reasons or while doing errands, their sensitivity would normally be average. However, when motorists are traveling for pleasure, or sightseers are present, it is likely that they would be somewhat more sensitive to their surroundings. The level of sensitivity increases, based on the level of familiarity the person has with the visual setting and the viewer's concern for scenic quality (e.g., Venice residents who regularly walk the Ballona Lagoon or Grand Canal versus persons who seldom visit). High viewer exposure heightens the importance of early consideration of design, art, and architecture and their roles in managing the visual resource effects of a project.

Few qualitative standards exist to guide analysts when determining impacts on visual resources. To help establish objective baseline conditions, photographs were taken of key views in the project area, as shown in Figures 3.1-2A and 3.1-3A.

Key Views

A key view is a point from which a select view is analyzed from the perspective of potential key viewer groups. Two key views have been selected that most clearly convey the visual setting. As mentioned, key views represent the perspective of the primary viewer groups, those that could be affected by the project.

A view is considered key if at least one of the following circumstances applies:

- Visual resources are present, regardless of the quality of the view. The sensitivity of the affected viewer group is medium or high, and the duration of the view is long term.
- The quality of the view is medium or high, regardless of whether visual resources are present. The sensitivity of the viewer group is medium or high, and the duration of the view is long term.
- The view is distinct, clear, and unobstructed from the street to adjacent businesses and viewed regularly by a large number of commuters. In this case, the viewer sensitivity would be medium, and the view would be long term.

Figures 3.1-2A and 3.1-3A capture the selected key views of the existing visual setting within the project area; these are identified by the location and direction of view. Figures 3.1-2B and 3.1-3B, which follow, capture the key views that could noticeably change as a result of the project; these use simulations to show the same views as Figures 3.1-2A and 3.1-3A but with project features included (see Section 3.1.3, Environmental Impact Analysis).

As noted above, two key views have been selected to document the visual character and quality of the project area and reflect the perspective of sensitive viewers (e.g., residents) and viewer groups. All key observation points (KOPs) have been evaluated using "before-and-after" visual simulations. The KOPs identified for this analysis are listed below.

- **Key View 1: Pacific Avenue (looking north, toward the Project Site).** The foreground of the view comprises a pedestrian landing, landscaped areas, and biological habitat adjacent to Ballona Lagoon and the Lagoon itself. The middleground comprises Ballona Lagoon, residential buildings of up to three stories, and adjacent trees and greenscaped areas. As one moves from the middleground to the background, the existing VPP and residential buildings of varying height, which form a horizontal line pattern and the backdrop for lines of sight from this view, are visible, as is the Lagoon's confluence with the Grand Canal.
- **Key View 2: Marquesas Way (looking southwest, toward the Project Site).** The foreground of this view comprises the Grand Canal. The middleground includes the existing VPP, the proposed vacant site for the VAPP, and adjacent residential buildings. The background depicts additional adjacent residential buildings, adjacent trees/landscaping, and partial keystoning (e.g., succession of buildings in a line) down Hurricane Street.

The location and angle of the key view photographs relative to the immediate project vicinity is mapped below in Figure 3.1-1. Key Views 1 and 2 are shown thereafter in Figures 3.1-2A and 3.1-3A.

3.1.3.2 Screening Analysis

As noted in Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A (Notice of Preparation/Initial Study) of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in Appendix G of the CEQA Guidelines and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.1.3.3 Thresholds of Significance

The criteria used to determine the significance of an impact on aesthetics are based on the *L.A. CEQA Thresholds*. A project would normally have a significant impact on aesthetics if it could result in significant impacts related to the following:

1. AES-1. The number or relative proportion of existing features or elements that substantially contribute to the valued visual character or image of a neighborhood, community, or localized area that would be removed, altered, or demolished.
2. AES-2. The amount of natural Open Space to be graded or developed.
3. AES-3. The degree to which proposed structures in natural Open Space areas would be effectively integrated into the aesthetics of the site through appropriate design, etc.
4. AES-4. The degree of contrast between proposed features and existing features that represent the area's valued aesthetic image.
5. AES-5. The degree to which a proposed zone change would result in buildings that would detract from the existing style or image of the area because of density, height, bulk, setbacks, signage, or other physical elements.

6. AES-6. The degree to which the project would contribute to the area's aesthetic value.
7. AES-7. Applicable guidelines and regulations.

Obstruction of Views

1. VIEWS-1. The nature and quality of recognized or valued views (e.g., natural topography, settings, human-made or natural features of visual interest, resources such as mountains or the ocean).
2. VIEWS-2. Whether the project affects views from a designated scenic highway, corridor, or parkway.
3. VIEWS-3. The extent of obstruction (e.g., total blockage, partial interruption, minor diminishment).
4. VIEWS-4. The extent to which the project affects recognized views available from a length of a public roadway, bike path, or trail as opposed to a single fixed vantage point.

Shading

1. SHADE-1. Whether shadow-sensitive uses would be shaded by project-related structures for more than 3 hours between 9 a.m. and 3 p.m. Pacific Standard Time (between late October and early April) or for more than 4 hours between 9 a.m. and 5 p.m. Pacific Daylight Time (between early April and late October).

Nighttime Illumination

1. LIGHT-1. The change in ambient illumination levels as a result of project sources.
2. LIGHT-2. The extent to which project lighting would spill off the Project Site and affect adjacent light-sensitive areas.

3.1.3.4 Construction Impacts

The analysis below describes the direct and indirect impacts on aesthetics as a result of the Proposed Project during construction. The analysis evaluate the overall aesthetic character and quality and the existing visual environment. Key Views, associated visual simulations, and other resources are used in order to establish the visual setting, identify visual resources throughout the project area(s), and identify potential visual intrusions that could occur as a result of construction. As noted in the analysis below, all impacts would be less than significant and no mitigation measures are required. However, although not required, during construction, mitigation measures or best management practices (BMPs) (related to dust generated during construction) are recommended to further reduce and minimize impacts and are discussed below.

AES-1. The number or relative proportion of existing features or elements that substantially contribute to the valued visual character or image of a neighborhood, community, or localized area that would be removed, altered, or demolished.

Construction activities associated with the Proposed Project, because of their short-term nature, would have no long-term effect on the existing features or elements that substantially contribute to the visual character or image of the neighborhood, community, or project area. Although, proposed construction would result in a temporary disturbance because of the presence of construction

equipment, staging areas, exposed excavation areas and the temporary cofferdam that would be visible to nearby viewers. However, there would be no long-term effect on the scenic or primary visual resources, as identified above in Section 3.1.2, *Environmental Setting*, because none of the existing features or contributing elements, such as Ballona Lagoon, would be removed, altered, or demolished as a result of construction. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

AES-2. The amount of natural Open Space to be graded or developed.

Construction would require grading and excavation at the Project Site and a portion of the west bank of the Grand Canal in the location of the temporary cofferdam in order to construct the diversion structure. The Project Site is currently undeveloped; it contains no natural Open Space that would be graded or developed. However, the west bank of the Grand Canal contains some native and non-native plant communities. As part of U.S. Army Corps of Engineers permit requirements, and consistent with **Mitigation Measure MM-BIO-3** (revegetation of the disturbance footprint associated with the west bank of the Grand Canal) any disturbance to the west bank of the Grand Canal would need to be restored. Therefore, because this area would be restored to its pre-project conditions, impacts on open space would be **less than significant**, and no mitigation measures are required.

AES-3. The degree to which proposed structures in natural Open Space areas would be effectively integrated into the aesthetics of the site through appropriate design, etc.

The Project Site would not be located in a natural Open Space area. However, the Project Site is located adjacent to a state, county, and City-designated ESHA, as identified within the Venice Local Coastal Program Land Use Plan. Construction activities would not involve integrating structures into existing natural Open Space areas other than construction of the diversion structure, which would be constructed below the Grand Canal and would not protrude into the water column. However, the presence of construction vehicles, the cofferdam and the necessary materials for construction that would be present in the Grand Canal would create a temporary visual intrusion in an area designated as Open Space. Nonetheless, due to the temporary nature of construction, and because the Grand Canal and west bank would be restored to their pre-project conditions (see **Mitigation Measure MM-BIO-3**), impacts would be **less than significant,** and no mitigation measures are required.

AES-4. The degree of contrast between proposed features and existing features that represent the area's valued aesthetic image.

As mentioned above, because of the short-term nature of construction activities, no long-term effect on the area's valued aesthetic image is expected. Though visual intrusions would occur due to the presence of construction vehicles/materials, associated fencing, and the placement of the cofferdam within the Grand Canal, the temporary nature of construction, and because the Grand Canal and west bank would be restored to their pre-project conditions (**see Mitigation Measure MM-BIO-3**), these impacts would be **less than significant**, and no mitigation measures are required.

AES-5. The degree to which a proposed zone change would result in buildings that would detract from the existing style or image of the area because of density, height, bulk, setbacks, signage, or other physical elements.

The Proposed Project does not require a zone change from its current zone of RW2-1 (Residential Water Ways) to PF (Public Facilities) because the use qualifies as a Public Benefit Project so no zone

change is required. The Public Benefit Project is not being pursued to accommodate greater or taller structures than surrounding structures and, therefore, would not otherwise detract from the existing style or image of the area as a result of changes related to density, height, bulk, setback, signage, or other physical elements. The vertical elements proposed as part of the Proposed Project (up to approximately 32 feet) are consistent with surrounding land uses, and compliance with applicable City regulations and standards would ensure that appropriate density, height, bulk, etc., would be adhered to as part of the facility's design. Therefore, **no impacts** would occur, and no mitigation measures are required.

AES-6. The degree to which the project would contribute to the area's aesthetic value.

Construction activities, which are expected to begin in early 2018 and last approximately two years, would not contribute to the area's aesthetic value. During construction, site preparation and grading activities, construction staging, barricade installation, and the placement of structures and signage would be required to secure the construction site. Construction activities would also include the installation of a temporary cofferdam within the Grand Canal, which would temporarily diminish the visual quality or character of the immediate area. Similarly, the delivery and stockpiling of construction materials and the placement of construction equipment on the Project Site might also temporarily diminish the visual quality or character of the immediate area. However, although not required, **Mitigation Measures MM-AES-1** (screening of construction staging and stockpile areas) **and MM-AES-2** (directing nighttime lighting away from sensitive receptors) are recommended to further reduce aesthetic impacts during construction. Therefore, the Proposed Project would contribute to the area's aesthetic value would be **less than significant**, and no mitigation measures are required.

AES-7. Applicable guidelines and regulations.

All project construction would be completed in conformance with applicable City regulations and standards and therefore, impacts would be **less than significant**, and no mitigation measures are required.

Obstruction of Views

VIEWS-1. The nature and quality of recognized or valued views (e.g., natural topography, settings, human-made or natural features of visual interest, resources such as mountains or the ocean).

As discussed in Section 3.1.2, *Environmental Setting*, the primary visual resources in the project area are Ballona Lagoon and Grand Canal. Project construction would not result in a long-term effect on the nature or quality of valued public views in the immediate project vicinity. However, as discussed above, temporary construction activities could diminish visual quality or character and, thus, valued views of the immediate area. During construction, site preparation and grading activities, construction staging, barricade installation, and the placement of structures and signage would be required to secure the construction site. Construction activities would also include the installation of a temporary cofferdam within the Grand Canal, which would temporarily diminish the nature and quality of recognized or valued views in the immediate area. Similarly, the delivery and stockpiling of construction materials and the placement of construction equipment on the Project Site might also temporarily diminish the nature and quality of recognized or valued views. Once construction is complete, valued views and the primary visual resources therein (Ballona Lagoon and/or Grand Canal) would be preserved and restored to their pre-project conditions, as required in **Mitigation**

Measure MM-BIO-3 (see above). Therefore, impacts would be temporary, and as such, **less than significant**, and no mitigation measures are required.

VIEWS-2. Whether the project affects views from a designated scenic highway, corridor, or parkway.

Certification of the Venice Local Coastal Program Land Use Plan (Venice LUP) is currently pending approval by the California Coastal Commission. However, although it has not been certified, the LUP nevertheless addresses issues related to coastal development and design that preserve and enhance coastal views, viewpoint areas, and Open Space. In that capacity, the LUP identifies Ballona Lagoon and Grand Canal as ESHAs for their recreational, residential, and scenic uses. No other officially designated scenic resources, vistas, corridors or eligible/officially designated State or County Scenic Highways have been identified within the project viewshed by Caltrans or within the Mobility Plan 2035. As discussed in Section 3.1.2, *Environmental Setting*, because no officially designated scenic highways, corridors, or parkways have been identified within the immediate project vicinity, **no impacts** would occur, and no mitigation measures are required.

VIEWS-3. The extent of obstruction (e.g., total blockage, partial interruption, or minor diminishment).

Project construction would result in a temporary minor diminishment and partial obstruction of views in the immediate project vicinity. Standard construction equipment would be used including compactors, bulldozers, front loaders, trenchers, construction cranes, water trucks, dump trucks, and delivery trucks that would bring construction-related materials to the site. This equipment, vehicle traffic, and the presence of construction workers would obstruct views in the area and result in minor diminishment and partial obstruction of views throughout the project area. However, large, overhead cranes would not be required; therefore, views of visual resources would not be substantially obstructed by this type of construction equipment or similar types of equipment, nor would the presence of construction equipment result in total blockage. Partial interruption and/or minor diminishment would occur in places with sightlines to Ballona Lagoon and/or Grand Canal, depending on the location, distance, speed, and angle of the viewer. Residential viewer groups and regular visitors to the lagoon and canal would be more sensitive to this type of temporary visual intrusion than recreationists or local commuters. However, project construction would not permanently block these visual resources or substantially diminish the nature and quality of recognized or valued private and public views. Because construction activities and the presence of construction equipment would be temporary, and because the project areas would be restored to pre-project conditions, no long-term obstruction of views, including those depicted in Key Views 1 and 2, as shown in Figure 3.1-2A and Figure 3.1-3A, would occur. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

VIEWS-4. The extent to which the project affects recognized views available from a length of a public roadway, bike path, or trail, as opposed to a single fixed vantage point.

As discussed above, the presence of construction materials and equipment would alter existing views, and project construction would result in temporary, minor visual intrusions. However, upon completion of construction of the Proposed Project, recognized views would be preserved and maintained. Roadway users on Marquesas Way and Via Dolce would have more fleeting views of the project area, which would lessen any temporary impacts. From the bike path and trail that connects

Hurricane Street to Pacific Avenue (south of the Proposed Site), access to which would be limited during construction because of temporary closures near Hurricane Street (see Figure 2-2 in Chapter 2, Project Description) to accommodate construction activities, views of the Proposed Site are limited due to the presence of the existing pumping plant, which mostly blocks the project area (as depicted in Figure 3.1-2A). Therefore, any impacts would be temporary, and as such, are **less than significant, and no mitigation measures are required.**

Shading

SHADE-1. Whether shadow-sensitive uses would be shaded by project-related structures for more than 3 hours between 9 a.m. and 3 p.m. Pacific Standard Time (between late October and early April) or for more than 4 hours between 9 a.m. and 5 p.m. Pacific Daylight Time (between early April and late October).

Construction is not expected to require large cranes or other major construction-related structures and equipment that would cast large shadows. Standard construction equipment would be used, including compactors, bulldozers, front loaders, trenchers, construction cranes, water trucks, dump trucks, and delivery trucks to bring construction-related materials to the site. Similarly, the vertical elements proposed as part of the project (greater than 32 feet), which would be under construction, would not cast shadows that would affect shade-sensitive uses or viewers. Therefore, impacts would be **less than significant** during construction of the Proposed Project. No mitigation is required.

Nighttime Illumination

LIGHT-1. The change in ambient illumination levels as a result of project sources.

Ambient illumination near the existing Project Site includes light emitted from residences on Hurricane Street, Canal Court, and Marquesas Way/Via Dolce; on-site lighting at the existing pumping plant; lampposts; and headlights from vehicle traffic. Of the land uses in the immediate project vicinity, the residences on Hurricane Street, Canal Court, and Marquesas Way/Via Dolce, would be the most light sensitive. During construction, some perimeter lighting may be required, both on the Project Site and in Laydown Areas 1 and 2, for security purposes.

If nighttime lighting at the construction site is required, lighting would be directed downward/on-site, away from sensitive receptors (residences), and spillover light would be minimized to the greatest extent practicable, but could be potentially significant. However, through compliance with Articles 1 and 9 of the LAMC, significant changes in ambient illumination levels as a result of project construction activities are not expected to occur. Though construction lighting may be somewhat visible to sensitive receptors, it would not be a significant nuisance for nearby residents due its directional orientation, which would minimize spill effects. Moreover, **Mitigation Measure MM-AES-2** (requiring the contractor to direct nighttime lighting away from sensitive receptors) would assist in reducing this impact. As such, since any construction lighting would adhere to LAMC requirements, and would be limited to the construction period, impacts would be **less than significant with implementation of Mitigation Measure MM-AES-2.**

LIGHT-2. The extent to which project lighting would spill off the Project Site and affect adjacent light-sensitive areas.

As mentioned above, if nighttime lighting at the construction site is required, lighting would be directed downward, and spillover light would be minimized to the greatest extent practicable.

Therefore, it is expected that project lighting would not spill off the Project Site and significantly affect adjacent light-sensitive areas. Construction lighting would not be a significant nuisance for nearby residents. As such, impacts would be **less than significant**, and no mitigation measures are required.

3.1.3.5 Operational Impacts

The section below discusses potential impacts associated with on-going and permanent operation of the Proposed Project related to overall aesthetic character and quality and the existing visual environment. Key views, associated visual simulations, and other resources are used to establish the visual setting, identify visual resources throughout the project area, and identify potential visual intrusions that could occur as a result of operation. It should be noted that the analysis does not address Laydown Area 3 located in Culver City since all stockpiled soil would be removed from this site once construction of the VAPP is completed. As noted in the analysis below, all impacts would be less than significant, and no mitigation measures are required. However, although not required, during operation, a mitigation measure is recommended to further reduce and minimize impacts and is discussed below.

Aesthetics

AES-1. The number or relative proportion of existing features or elements that substantially contribute to the valued visual character or image of a neighborhood, community, or localized area that would be removed, altered, or demolished.

The major visible built elements of the Proposed Project include the electrical building (up to 32 feet in height), Open Spaces (located along the eastern side of the VAPP and adjacent parcel to the southwest), landscaping and benches, pathways, public viewing and pedestrian access areas, as well as fencing with blinds and vegetation for screening. Other project elements, including sewer lines, utility connections, transformers, generators, and a diversion structure, would be minimally visible, subterranean, and/or submerged beneath the Grand Canal and, therefore, would not be present in the viewsheds throughout the immediate project vicinity. Photo simulations of the VAPP, once built, are provided in Figures 3.1-2B and 3.1-3B and illustrate the expected changes in the visual setting compared with existing conditions as a result of the Proposed Project. The built features, as shown in Figures 3.1-2B and 3.1-3B, would not remove, alter, or demolish existing features or elements that contribute to the visual character of the project area, primarily Ballona Lagoon and Grand Canal. From Key View 1, built features would be minimally present. From Key View 2, built features would not interfere with existing features that contribute to the project area's visual character. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

AES-2. The amount of natural Open Space to be graded or developed.

The Project Site is currently undeveloped. It contains no natural Open Space that would be graded or developed, except the west bank of the Grand Canal where the diversion structure would be constructed below ground and would not visibly protrude into the water column. As noted above and required under **Mitigation Measure MM-BIO-3**, this portion of the bank would be restored to its pre-existing contours and restored with native plant communities in compliance with U.S. Army Corps of Engineers permit requirements. Moreover, the Proposed Project would provide additional Open Space and pedestrian access to the Grand Canal. Therefore, **no significant impacts** on open space would occur, and no mitigation measures are required.

AES-3. The degree to which proposed structures in natural Open Space areas would be effectively integrated into the aesthetics of the site through appropriate design, etc.

The Project Site would not be located in a natural Open Space area. However, the Project Site is located adjacent to a state, county, and City-designated ESHA, as identified within the LUP. As shown in Figure 3.1-3B, the VAPP would be setback from Grand Canal and Ballona Lagoon. It would include, in compliance with the policies and regulations outlined in this section and throughout the EIR related to height, massing and setback, appropriate design features, which would be subject to review and approval by the project design team and City Engineer/City Architect. As such, the visible built elements of the Proposed Project would generally be in keeping with development in the immediate project vicinity that is adjacent to the ESHA. Therefore, it would be effectively integrated into the aesthetics of the project area. As such, impacts related to the degree to which proposed structures in natural Open Space areas would be effectively integrated into the aesthetics of the site through appropriate design, etc., would be less than significant and no mitigation measures are required. However, although not required, **Mitigation Measure MM-AES-3** (compliance with City-required design guidance), which requires structures to be designed and built to the satisfaction of the Department of City Planning and the City Engineer/City Architect and in compliance with all applicable design guidelines, policies, and development standards, is recommended to further reduce any aesthetic impacts and/or inconsistencies between the Proposed Project and the surrounding areas.

AES-4. The degree of contrast between proposed features and existing features that represent the area's valued aesthetic image.

As shown in Figure 3.1-2B, from Key View 1, which is located on Pacific Avenue (looking north, toward the Project Site), the VAPP would be minimally perceptible and visually unobtrusive. Governing land use policies and design guidelines would ensure that visible project elements would be appropriate to the surrounding development with respect to density, height, and setbacks; would be required to incorporate visual treatments to be in keeping with the existing visual setting and environment; and would be situated next to the existing VPP, as shown in Figure 3.1-3B. Furthermore, under **Mitigation Measure MM-AES-3**, structures shall be designed and built to the satisfaction of the Department of City Planning and the City Engineer/City Architect. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

AES-5. The degree to which a proposed zone change would result in buildings that would detract from the existing style or image of the area because of density, height, bulk, setbacks, signage, or other physical elements.

As discussed above, the Proposed Project would not require a zone change from its current zone of RW2-1 to PF because the Proposed Project qualifies as a Public Benefit Project and no zone change is required (see discussion above). A Public Benefit Project is not being pursued to accommodate greater or taller structures than surrounding structures and, therefore, would not otherwise detract from the existing style or image of the area as a result of changes related to density, height, bulk, setback, signage, or other physical elements. The vertical elements proposed as part of the project (up to approximately 32 feet) would be consistent with surrounding land uses, and compliance with applicable City regulations and standards would ensure that appropriate density, height, bulk, etc., would be adhered to as part of the facility's design. Built features associated with the Proposed Project are shown in Figures 3.1-2B and 3.1-3B. Therefore, **no impacts** would occur, and no mitigation measures are required.

AES-6. The degree to which the project would contribute to the area's aesthetic value.

Built elements of the Proposed Project include an electrical building (up to approximately 32 feet in height), security walls, and Open Spaces and landscaping. The Open Spaces, landscaping and aesthetically treated walls would enhance visual quality and would contribute to the overall cohesion and continuity of the Proposed Project with adjacent buildings and the Ballona Lagoon and Grand Canal by providing color and scenic relief. Though visible, Proposed Project elements would not substantially alter the visual quality and/or character of the project's visual setting because of the project's adherence to applicable design guidelines, as discussed in Section 3.1.1, *Regulatory Setting*. Views throughout the immediate project vicinity would still be of medium quality, maintaining variety with respect to vegetation and color. Similarly, viewsheds throughout the immediate project vicinity would retain their intactness through a combination of well-kept urban features and natural settings, which would continue to be somewhat free of encroaching man-made elements. The project area would also retain its vividness because the Proposed Project's built elements would preserve the juxtaposition of water and landscape features with surrounding elements, such as residential buildings and the existing VPP. Overall, the project area would remain fairly unified, and the Proposed Project would not substantially compromise the visual coherence, line patterns, or overall scenery.

As a result of the additional Open Space and pedestrian access to the Grand Canal, the response from viewer groups, including residents, recreationists, local commuters, etc., is expected to be moderate and positive. Though viewer exposure and sensitivity would be higher for more accustomed viewer groups (i.e., residences and frequent visitors), given the nature and quality of existing viewsheds and the presence of the existing VPP, the Proposed Project would not substantially diminish or alter the aesthetic value of the project area. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

AES-7. Applicable guidelines and regulations.

The Proposed Project would be implemented in conformance with applicable City regulations and standards (see Chapter 2, Project Description, and Section 3.8, Land Use and Planning, of this EIR) and therefore, impacts related to applicable guidelines and regulations would be less than significant, and no mitigation measures are required. However, although not required, implementation of **Mitigation Measure MM-AES-3**, which requires structures be designed and built to the satisfaction of the City Engineer/City Architect and in compliance with all applicable design guidelines, policies, and development standards, would help to further reduce and minimize visual impacts.

Obstruction of Views

VIEWS-1. The nature and quality of recognized or valued views (e.g., natural topography, settings, human-made or natural features of visual interest, resources such as mountains or the ocean).

As discussed in Section 3.1.2, *Environmental Setting*, the primary visual resources in the project area are Ballona Lagoon and Grand Canal. Built features associated with the Proposed Project would not compromise the nature and/or quality of recognized or valued views. Project elements would be built in accordance with the applicable standards and guidelines and would be designed to be minimally apparent and in keeping with the surrounding visual environment, as discussed above

(and below) and shown in Figures 3.1-2B and 3.1-3B. Thus, valued views and views to/from the primary visual resources therein (Ballona Lagoon and/or Grand Canal) would be preserved. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

VIEWS -2. Whether the project affects views from a designated scenic highway, corridor, or parkway.

The Ballona Lagoon and Grand Canal are designated by the state, county, and City as an ESHA for their recreational, residential, and scenic uses. No other officially designated scenic resources, vistas, corridors, or eligible/officially designated State or County Scenic Highways have been identified within the project viewshed. As discussed in Section 3.1.2, *Environmental Setting*, because no officially designated scenic highways, corridors, or parkways have been identified by Caltrans or within the Mobility Plan 2035 in the immediate project vicinity, **no impacts** would occur, and no mitigation measures are required.

VIEWS -3. The extent of obstruction (e.g., total blockage, partial interruption, or minor diminishment).

As shown in Figure 3.1-2B, from Key View 1, the Proposed Project would be minimally perceptible and visually unobtrusive. In accordance with governing design guidelines and land use policies, visible project elements would be appropriate with respect to density, height, and setback and would be provided with visual treatments to be in keeping with the existing visual setting and environment. Views to/from primary and secondary visual resources, including Ballona Lagoon, would be unobstructed and preserved. As shown in Figure 3.1-3B, from Key View 2, the Proposed Project would partially block existing views. Although the VAPP would obstruct views of existing residential buildings, which are not considered visual resources, it would preserve views of the Grand Canal. Additionally, the aesthetically treated fencing and other landscape features included in the Proposed Project would enhance visual quality from this view. As a result of the additional Open Spaces and pedestrian access to Grand Canal and Ballona Lagoon, the response from viewer groups, including residents, recreationists, local commuters, etc., is expected to be moderate and positive. Though viewer exposure and sensitivity would be higher for more accustomed viewer groups (i.e., residences and frequent visitors), given the nature and quality of existing viewsheds and the presence of the existing VPP, the Proposed Project would not substantially diminish or alter valued views throughout the area. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

VIEWS -4. The extent to which the project affects recognized views available from a length of a public roadway, bike path, or trail, as opposed to a single fixed vantage point.

Built features associated with the Proposed Project would not result in impacts on recognized views from a length of a public roadway, bike path, or trail, such as those represented in Key View 1. Project elements would be built in accordance with applicable standards and guidelines and designed in keeping with the surrounding visual environment (e.g. scale, size, density, height, setback, etc.), as discussed above and shown in Figures 3.1-2B and 3.1-3B. Thus, recognized views from a length of a public roadway, bike path, or trail would be preserved. Therefore, impacts would be **less than significant**, and no mitigation is required.

Shading

SHADE-1. Whether shadow-sensitive uses would be shaded by project-related structures for more than 3 hours between 9 a.m. and 3 p.m. Pacific Standard Time (between late October and early April) or for more than 4 hours between 9 a.m. and 5 p.m. Pacific Daylight Time (between early April and late October).

In compliance with applicable plans and regulations, the scale and massing of visual elements associated with the Proposed Project would not result in shadows that would significantly affect shade-sensitive uses. The potential for the Proposed Project to cast new shadows or create shade would be limited and similar to that of existing uses/facilities within the project's viewshed. Projects with structural elements in excess of 60 feet in height (relative to nearby shade-sensitive uses) are required to determine the number of hours shadow-sensitive uses would be shaded by these elements. Since built elements associated with the VAPP would not exceed approximately 32 feet, no further analysis is required. Thus, impacts would be **less than significant** during operation, and no mitigation measures are required.

Nighttime Illumination

LIGHT-1. The change in ambient illumination levels as a result of project sources.

As discussed above, ambient illumination near the existing Project Site includes light emitted from residences on Hurricane Street, Canal Court, and Marquesas Way/Via Dolce; on-site lighting at the existing pumping plant; lampposts; and headlights from vehicle traffic. Perimeter security lighting would also be installed within the VAPP site, which would face inside, away from sensitive receptors, and be similar to those on the adjacent VPP site. Because substantial illumination, relative to existing conditions, would not be introduced by the Proposed Project, and because new lighting would be directed away from sensitive receptors, the Proposed Project would not significantly alter ambient light levels. Lighting would be installed in accordance with the LAMC, which would minimize the potential for spillover effects. Therefore, impacts would be **less than significant** during operation, and no mitigation measures are required.

LIGHT-2. The extent to which project lighting would spill off the Project Site and affect adjacent light-sensitive areas.

Nighttime lighting would be installed in accordance with the LAMC and the potential for spillover effects would be minimized. Therefore, it is expected that project lighting would not result in substantial adverse impacts on adjacent light-sensitive areas. Lighting would not be a significant nuisance for nearby residents. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

3.1.4 Mitigation Measures

Although the analysis above determined that no significant aesthetic or visual construction or operational-related impacts would occur, and no mitigation is required (excepting **Mitigation Measure MM-BIO-3** [discussed above]), in an effort to reduce perceived effects as much as practicable, several mitigation measures have been recommended for incorporation into the Proposed Project and are included below.

MM-AES-1: Construction Staging/Stockpiled Materials and Equipment. LABOE or its construction contractor shall be the responsible party for providing temporary construction fencing along the periphery of active construction areas to screen as much of the construction activity as possible from view at the street level.

To minimize views of stockpiled materials and idle construction equipment in staging areas and reduce visual clutter and disorder, project construction staging areas shall be enclosed or screened from view at the street level with appropriate screening materials. The contractor shall provide daily visual inspections to ensure that areas immediately surrounding the construction staging areas are free from construction-related clutter and graffiti and maintained in a clean and orderly manner throughout the construction period. Graffiti shall be painted over, masked out, or cleaned off within 24 hours after notification by the project inspector.

MM-AES-2: Nighttime Construction Activities. Should emergency construction activities occur at night, LABOE or its construction contractor shall ensure that lighting will be directed away from surrounding sensitive land uses, particularly residences, and toward the specific location intended for illumination. Lighting associated with construction activities or for security purposes shall be shielded to minimize glare and spill light around sensitive land uses in the surrounding area.

MM-AES-3: Final Design. LABOE shall ensure that all Proposed Project structures will be designed to minimize their visual presence. Where site and design allow, the project elements shall incorporate design and location features that minimize the size of the structures and provide setbacks from adjoining street frontages, screening, and/or architectural treatments that are appropriate to the design setting where visible from the public right-of-way at street level. Where necessary, structures shall be designed and built to the satisfaction of the City Engineer/City Architect and in compliance with all applicable design guidelines, policies, and development standards, as discussed Section 3.1.1, *Regulatory Setting*.

MM-BMP-AES-1: Resident Vouchers for Window Washing and Car Washes during Construction. LABOE or its construction contractor will implement best available control measures, as required by SCAQMD Rule 403 regarding fugitive dust, and other relevant regulations related to controlling dust from construction activities. However, to minimize any aesthetic impact construction dust may have on nearby neighboring cars and resident windows, the Public Affairs Office of the Department of Public Works shall provide vouchers to immediately adjacent residents for window washing and car washes, as appropriate.

3.1.5 Significant Unavoidable Adverse Impacts

No significant unavoidable adverse impacts related to aesthetics would occur as a result of the Proposed Project.

3.1.6 Cumulative Impacts

The study area for the cumulative impacts analysis is limited to locations that have clear sightlines to the built elements proposed as part of the Proposed Project. Typically, the study area boundaries extend approximately 0.25 miles from the project perimeter. Due to varying and constrained sightlines throughout the project vicinity, the study area for this cumulative impacts analysis are as follows: Galleon Street serves as the approximate northern border, Via Dolce/Marquesas Way create

a visual border on the east, Pacific Avenue creates a visual border to the west, and to the south, sightlines extend to/from the Project Site to approximately the intersection of Pacific Avenue and Ketch Street.

A list of related projects (see Chapter 1, Table 1-1) was reviewed as part of this cumulative impacts analysis. Of the total list of eight projects, three are within the project's cumulative viewshed—the Venice Dual Force Main, Venice Pumping Plant Vibration Rehab Phase 2 (under construction), and Venice Pumping Plant Generators Replacement Projects. Despite their proximity, these projects are and would only replace existing infrastructure and would consist of subterranean built elements. Therefore, they are not expected to adversely affect visual character and quality, nor result in effects that are potentially cumulatively significant.

Thus, because the Proposed Project would result in less-than-significant impacts, and would be designed and built to the satisfaction of the Department of City Planning and the City Engineer/City Architect and in compliance with all applicable design guidelines, policies, and development standards, it is not expected to result in or contribute to significant cumulative visual impacts.

3.2 Air Quality

This section discusses air quality in relation to the VAPP or Proposed Project. The section includes a discussion of regulatory requirements, the existing air quality within the Project area, and evaluates the potential for air quality impacts to occur as a result of Project construction and operation. As noted in the analysis below, impacts during both construction and operation would be less than significant and no mitigation measures are required. Supporting technical information and analyses are included as Appendix B (Air Quality Emissions and Greenhouse Gas Calculations) of this EIR.

3.2.1 Regulatory Setting

A review of the various federal, state, regional, and local government regulatory requirements was conducted to identify regulations that applicable to the Proposed Project relative to air quality. This section summarizes the various regulatory requirements that are relevant to the Proposed Project.

At the federal level, the U.S. Environmental Protection Agency (EPA) is responsible for implementation of the Clean Air Act (CAA). Some portions of the CAA (e.g., certain mobile-source and other requirements) are implemented directly by EPA; others (e.g., stationary-source requirements) are implemented by state and local agencies.

Responsibility for regulating air quality in California is shared between the California Air Resources Board (ARB) and the regional air quality districts. Areas of control for the regional districts are set by ARB, which divides the state into air basins (see Figure 3.2-1 for the boundaries of the South Coast Air Basin relative to the Proposed Project). ARB has establishes and runs programs for cleaner air ranging from research and regulation to enforcement and education. Specifically, ARB:

- Establishes and enforces emission standards for motor vehicles, fuels and consumer products.
- Has new authority to control climate change emissions.
- Establishes health-based air quality standards.
- Conducts research.
- Monitors air quality.
- Identifies and establishes control measures for toxic air contaminants.
- Provides compliance assistance for businesses.
- Produces education and outreach programs and materials.
- Oversees and assists local air quality districts, which regulate most non-vehicular sources of air pollution (ARB 2009).

The Proposed Project lies within the Los Angeles County portion of the South Coast Air Basin (Basin), which is under the jurisdiction of South Coast Air Quality Management District (SCAQMD). SCAQMD has jurisdiction over an area of approximately 10,743 square miles, including all of Orange County; Los Angeles County, except for the Antelope Valley; the non-desert portion of western San Bernardino County; and the western and Coachella Valley portions of Riverside County. The Basin is a sub-region of SCAQMD's jurisdiction.

SCAQMD is responsible for preparing the portion of the State Implementation Plan (SIP) applicable within its boundaries; adoption of control regulations for stationary sources; and implementation of indirect source and transportation control measures (e.g. employee ridesharing rules).

- Issuance of Permits: Under state law and district rules, every piece of equipment that emits or controls air pollution must have a permit to operate from the local air district. The equipment cannot be constructed without a district permit to construct. The district staff must issue the permit if the equipment will comply with all emission limitations in district rules.
- Enforcement: Permit requirements and district rules can be enforced by districts through actions for civil penalties (up to $75,000 per day of violation for individuals and up to $1 million per day for corporations), by local prosecutors through actions for misdemeanor criminal penalties, and by either seeking injunctive orders or orders of abatement.
- Hearing Boards: Hearing Boards in each district are authorized to issue temporary variances to sources having difficulty complying with air pollution rules. Hearing Boards can also hear appeals of permit decisions by the district staff, and can issue orders for abatement (SCAQMD, no date).

A discussion of the relevant air pollutants that are subject to regulatory control are discussed below, followed by a discussion of plans, policies, and regulations at the federal, state, and local level relevant to the Proposed Project.

3.2.1.1 Relevant Air Pollutants

Criteria Pollutants

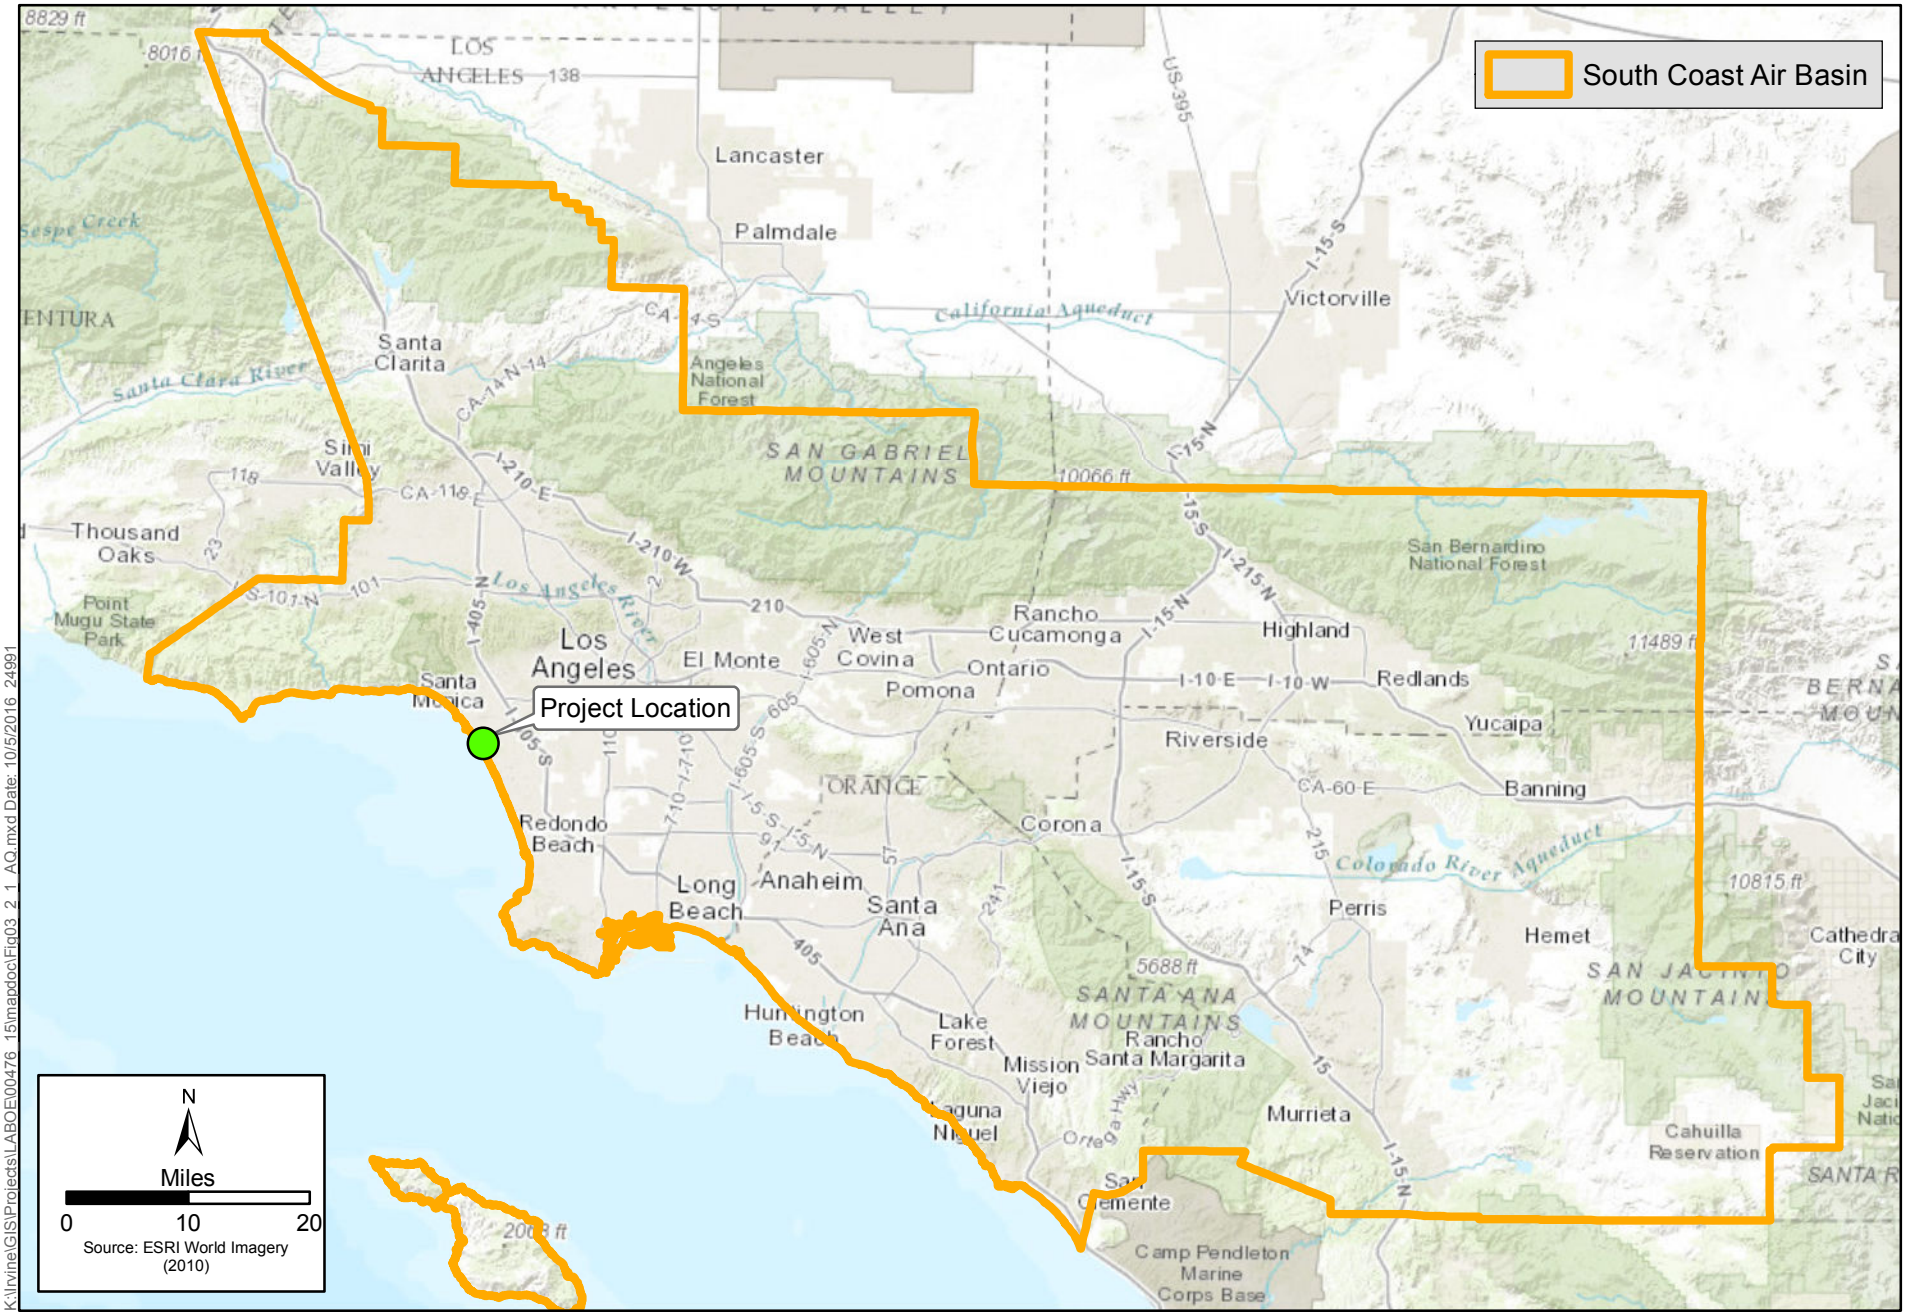
The federal and state governments have established national ambient air quality standards (NAAQS) and California ambient air quality standards (CAAQS), respectively, for six criteria pollutants: ozone, carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and particulate matter (PM), which consists of PM 10 microns in diameter or less (PM10) and PM 2.5 microns in diameter or less (PM2.5).

Ozone and NO_2 are considered regional pollutants because they (or their precursors) affect air quality on a regional scale; NO_2 reacts photochemically with reactive organic gases (ROGs) to form ozone, and this reaction occurs at some distance downwind of the source of pollutants. Pollutants such as CO, SO_2, and Pb are considered to be local pollutants that tend to accumulate in the air locally. Particulate matter is considered to be a local as well as a regional pollutant.

The primary pollutants of concern in the study area are ozone (including nitrogen oxides), CO, and PM. Principal characteristics surrounding these pollutants are discussed below. Toxic air contaminants (TACs) are also discussed, although no air quality standards exist for these pollutants. The descriptions of criteria pollutants below are based on the Final Program Environmental Impact Report prepared for the 2012 SCAQMD Air Quality Management Plan (SCAQMD 2012).

Ozone

Ozone (O_3), a colorless gas with a sharp odor, is a highly reactive form of oxygen. High ozone concentrations exist naturally in the stratosphere. Some mixing of stratospheric ozone downward through the troposphere to the earth's surface does occur; however, the extent of ozone transport is limited. At the earth's surface in sites remote from urban areas, ozone concentrations are normally very low (e.g., from 0.03 ppm to 0.05 ppm).



K:\Irvine\GIS\Projects\LABOE00476_15\mapdoc\Fig03_2_1_AQ.mxd Date: 10/5/2016 24991

Figure 3.2-1
South Coast Air Basin
Venice Auxiliary Pumping Plant Project

While ozone is beneficial in the stratosphere because it filters out skin-cancer-causing ultraviolet radiation, it is a highly reactive oxidant. It is this reactivity that accounts for its damaging effects on materials, plants, and human health at the earth's surface. The propensity of ozone for reacting with organic materials causes it to be damaging to living cells and ambient ozone concentrations in the Basin are frequently sufficient to cause health effects. Ozone enters the human body primarily through the respiratory tract and causes respiratory irritation and discomfort, makes breathing more difficult during exercise, and reduces the respiratory system's ability to remove inhaled particles and fight infection. Individuals exercising outdoors, children and people with preexisting lung disease, such as asthma and chronic pulmonary lung disease, are considered to be the most susceptible subgroups for ozone effects.

Short-term exposures (lasting for a few hours) to ozone at levels typically observed in southern California can result in breathing pattern changes, reduction of breathing capacity, increased susceptibility to infections, inflammation of the lung tissue, and some immunological changes. In recent years, a correlation between elevated ambient ozone levels and increases in daily hospital admission rates, as well as mortality, has also been reported. An increased risk for asthma has been found in children who participate in multiple sports and live in high ozone communities. Elevated ozone levels are also associated with increased school absences. Ozone exposure under exercising conditions is known to increase the severity of the abovementioned observed responses. Animal studies suggest that exposures to a combination of pollutants that include ozone may be more toxic than exposure to ozone alone. Although lung volume and resistance changes observed after a single exposure diminish with repeated exposures, biochemical and cellular changes appear to persist, which can lead to subsequent lung structural changes.

Nitrogen Oxides

NO_2 is a reddish-brown gas with a bleach-like odor. Nitric oxide (NO) is a colorless gas, formed from the nitrogen (N_2) and oxygen (O_2) in air under conditions of high temperature and pressure which are generally present during combustion of fuels; NO reacts rapidly with the oxygen in air to form NO_2. NO_2 is responsible for the brownish tinge of polluted air. The two gases, NO and NO_2, are referred to collectively as NOx. In the presence of sunlight, NO_2 reacts to form nitric oxide and an oxygen atom. The oxygen atom can react further to form ozone, via a complex series of chemical reactions involving hydrocarbons. Nitrogen dioxide may also react to form nitric acid (HNO3) which reacts further to form nitrates, components of PM2.5 and PM10.

Population-based studies suggest that an increase in acute respiratory illness, including infections and respiratory symptoms in children (not infants), is associated with long-term exposures to NO_2 at levels found in homes with gas stoves, which are higher than ambient levels found in southern California. Increase in resistance to air flow and airway contraction is observed after short-term exposure to NO_2 in healthy subjects. Larger decreases in lung functions are observed in individuals with asthma and/or chronic obstructive pulmonary disease (e.g., chronic bronchitis, emphysema) than in healthy individuals, indicating a greater susceptibility of these sub-groups. More recent studies have found associations between NO_2 exposures and cardiopulmonary mortality, decreased lung function, respiratory symptoms and emergency room asthma visits. In animals, exposure to levels of NO2 considerably higher than ambient concentrations results in increased susceptibility to infections, possibly due to the observed changes in cells involved in maintaining immune functions. The severity of lung tissue damage associated with high levels of ozone exposure increases when animals are exposed to a combination of ozone and NO_2.

Carbon Monoxide

CO is a colorless, odorless, relatively inert gas. It is a trace constituent in the unpolluted troposphere, and is produced by both natural processes and human activities. In remote areas far from human habitation, carbon monoxide occurs in the atmosphere at an average background concentration of 0.04 ppm, primarily as a result of natural processes such as forest fires and the oxidation of methane. Global atmospheric mixing of CO from urban and industrial sources creates higher background concentrations (up to 0.20 ppm) near urban areas.

The major source of CO in urban areas is incomplete combustion of carbon-containing fuels, mainly gasoline. According to the 2007 AQMP, in 2002, the inventory baseline year, approximately 98 percent of the CO emitted into the Basin's atmosphere was from mobile sources. Consequently, CO concentrations are generally highest in the vicinity of major concentrations of vehicular traffic. CO is a primary pollutant, meaning that it is directly emitted into the air, not formed in the atmosphere by chemical reaction of precursors, as is the case with ozone and other secondary pollutants. Ambient concentrations of CO in the Basin exhibit large spatial and temporal variations due to variations in the rate at which CO is emitted and in the meteorological conditions that govern transport and dilution. Unlike ozone, CO tends to reach high concentrations in the fall and winter months. The highest concentrations frequently occur on weekdays at times consistent with rush hour traffic and late night during the coolest, most stable portion of the day.

Particulate Matter

Of great concern to public health are the particles small enough to be inhaled into the deepest parts of the lung. Respirable particles (particulate matter less than about 10 micrometers in diameter) can accumulate in the respiratory system and aggravate health problems such as asthma, bronchitis, and other lung diseases. Children, the elderly, exercising adults, and those suffering from asthma are especially vulnerable to adverse health effects of PM10 and PM2.5.

A consistent correlation between elevated ambient PM10 and PM2.5 levels and an increase in mortality rates, respiratory infections, number and severity of asthma attacks, and the number of hospital admissions has been observed in different parts of the United States and various areas around the world. Studies have reported an association between long-term exposure to air pollution dominated by PM2.5 and increased mortality, reduction in life-span, and an increased mortality from lung cancer.

Daily fluctuations in fine particulate matter concentration levels have also been related to hospital admissions for acute respiratory conditions, to school and kindergarten absences, to a decrease in respiratory function in normal children, and to increased medication use in children and adults with asthma. Studies have also shown lung function growth in children is reduced with long-term exposure to particulate matter. In addition to children, the elderly, and people with pre-existing respiratory and/or cardiovascular disease appear to be more susceptible to the effects of PM10 and PM2.5.

Sulfur Oxides

SO_2 is a colorless gas with a sharp odor. It reacts in the air to form sulfuric acid (H_2SO_4), which contributes to acid precipitation, and sulfates, which are components of PM10 and PM2.5. Most of the SO_2 emitted into the atmosphere is produced by burning sulfur-containing fuels. Exposure of a few minutes to low levels of SO_2 can result in airway constriction in some asthmatics. All asthmatics

are sensitive to the effects of SO_2. In asthmatics, increase in resistance to air flow, as well as reduction in breathing capacity leading to severe breathing difficulties, is observed after acute higher exposure to SO_2. In contrast, healthy individuals do not exhibit similar acute responses even after exposure to higher concentrations of SO_2.

Lead

Lead in the atmosphere is present as a mixture of a number of lead compounds. Leaded gasoline and lead smelters have been the main sources of lead emitted into the air. Due to the phasing out of leaded gasoline, there was a dramatic reduction in atmospheric lead in the Basin over the past three decades.

Fetuses, infants, and children are more sensitive than others to the adverse effects of lead exposure. Exposure to low levels of lead can adversely affect the development and function of the central nervous system, leading to learning disorders, distractibility, inability to follow simple commands, and lower intelligence quotient. In adults, increased lead levels are associated with increased blood pressure.

Lead poisoning can cause anemia, lethargy, seizures, and death. It appears that there are no direct effects of lead on the respiratory system. Lead can be stored in the bone from early age environmental exposure, and elevated blood lead levels can occur due to breakdown of bone tissue during pregnancy, hyperthyroidism (increased secretion of hormones from the thyroid gland), and osteoporosis (breakdown of bone tissue). Fetuses and breast-fed babies can be exposed to higher levels of lead because of previous environmental lead exposure of their mothers.

Toxic Air Contaminants

Although NAAQS and CAAQS exist for criteria pollutants, no ambient standards exist for Toxic Air Contaminants (TACs). Many pollutants are identified as TACs because of their potential to increase the risk of developing cancer or because of their acute or chronic health risks. For TACs that are known or suspected carcinogens, the ARB has consistently found that there are no levels or thresholds below which exposure is risk-free. Individual TACs vary greatly in the risks they present. At a given level of exposure, one TAC may pose a hazard that is many times greater than another. TACs are identified and their toxicity is studied by the California Office of Environmental Health Hazard Assessment (OEHHA). TACs include air pollutants that can produce adverse human health effects, including carcinogenic effects, after short-term (acute) or long-term (chronic) exposure. Examples of TAC sources include industrial processes, dry cleaners, gasoline stations, paint and solvent operations, and fossil fuel combustion sources (including diesel particulate matter[DPM]). For certain TACs, a unit risk factor can be developed to evaluate cancer risk. For acute and chronic health risks, a similar factor, called a Hazard Index, is used to evaluate risk.

3.2.1.2 Applicable Regulations

Federal

The CAA establishes the National Ambient Air Quality Standards (NAAQS) for maximum concentrations of a particular pollutant and specifies future dates for achieving compliance, it was first enacted in 1963, but has been amended numerous times in subsequent years (1967, 1970, 1977, and 1990). The CAA identifies two types of national ambient air quality standards. Primary standards provide public health protection, including protecting the health of "sensitive"

populations such as asthmatics, children, and the elderly. Secondary standards provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings. The CAA mandates that the state submit a State Implementation Plan (SIP) for regions that fail to meet the standards. The plans must include pollution control measures that demonstrate how the standards will be met. The City of Los Angeles is within the South Coast Air Basin, which is designated as a nonattainment area for certain pollutants that are regulated under the CAA.

The 1990 amendments to the CAA identify specific emissions-reduction goals for areas that fail to meet the NAAQS. These amendments require both a demonstration of reasonable further progress toward attainment and incorporation of additional sanctions for failure to attain or meet interim milestones. The sections of the CAA that would most substantially affect development of the Proposed Project include Title I (Nonattainment Provisions) and Title II (Mobile-Source Provisions). Title I provisions were established with the goal of attaining the NAAQS for criteria pollutants. Table 3.2-1 shows the NAAQS that are currently in effect for each criteria pollutant. The NAAQS were amended in July 1997 to include an 8-hour standard for O_3 and adopt a standard for PM2.5. The 8-hour ozone NAAQS was further amended in October 2015. EPA will designate ozone attainment and nonattainment areas in late 2017.

State

The California Clean Air Act (CCAA), signed into law in 1988, requires all areas of the state to achieve and maintain the CAAQS by the earliest practical date. The CAAQS incorporate additional standards for most of the criteria pollutants and set standards for other pollutants recognized by the state. In general, the California standards are more health protective than the corresponding NAAQS. California has also set standards for sulfates, hydrogen sulfide, vinyl chloride, and visibility-reducing particles that are not included in the NAAQS. The Basin is in compliance with the California standards for sulfates, hydrogen sulfide, visibility-reducing particles, and vinyl chloride. As is the case with the NAAQS, compliance dates for attainment of the CAAQS have been set according to the severity of the violation of the standards. Table 3.2-1 details the current NAAQS and CAAQS, and Table 3.2-2 provides the Los Angeles County portion of the Basin's attainment status with respect to NAAQS and CAAQS.

Toxic Air Contaminants

With respect to criteria pollutants, federal and/or state ambient air quality standards (AAQS) represent the exposure level (with an adequate margin of safety) deemed safe for humans. No AAQS exist for TACs because no exposure level has been deemed safe for humans. Pollutants are identified as TACs because of their potential to increase the risk of developing cancer or their acute or chronic health risks. For TACs that are known or suspected carcinogens, ARB has consistently found that there are no levels or thresholds below which exposure is risk free. Individual TACs vary greatly in the risk they present. At a given level of exposure, one TAC may pose a hazard that is many times greater than another. For certain TACs, a unit risk factor can be developed to evaluate cancer risk. For acute and chronic health risks, a similar factor, called a Hazard Index, is used to evaluate risk. In the early 1980s, ARB established a statewide comprehensive air toxics program to reduce exposure to air toxics. The Toxic Air Contaminant Identification and Control Act (Assembly Bill [AB] 1807) created California's program to reduce exposure to air toxics. The Air Toxics "Hot Spots" Information and Assessment Act (AB 2588) supplements the AB 1807 program by requiring a statewide air toxics inventory,

Table 3.2-1. Federal and State Ambient Air Quality Standards

Pollutant	Averaging Time	CAAQS[a]	NAAQS[b]
Ozone (O_3)	1 hour	0.09 ppm[c]	—
	8 hour	0.070 ppm	0.070 ppm
Carbon Monoxide (CO)	1 hour	20 ppm	35 ppm
	8 hour	9.0 ppm	9 ppm
Nitrogen Dioxide (NO_2)	1 hour	0.18 ppm	100 ppb
	Annual Arithmetic Mean	0.030 ppm	53 ppb
Sulfur Dioxide (SO_2)	1 hour	0.25 ppm	75 ppb
	24 hour	0.04 ppm	0.14 ppm
Respirable Particulate Matter (PM10)	24 hour	50 µg/m^3 [c]	150 µg/m^3
	Annual Arithmetic Mean	20 µg/m^3	—
Fine Particulate Matter (PM2.5)	24 hour	—	35 µg/m^3
	Annual Arithmetic Mean	12 µg/m^3	12.0 µg/m^3
Sulfates	24 hour	25 µg/m^3	—
Lead (Pb)	30 day average	1.5 µg/m^3	—
	Calendar quarter	—	1.5 µg/m^3
	Rolling 3-Month Average	—	0.15 µg/m^3
Hydrogen Sulfide	1 hour	0.03 ppm	—
Vinyl Chloride	24 hour	0.01 ppm	—

Notes:
[a] The CAAQS for O_3, CO, SO_2 (1-hour and 24-hour), NO_2, PM_{10}, and $PM_{2.5}$ are values not to be exceeded. All other California standards shown are values not to be equaled or exceeded.
[b] The NAAQS, other than O_3 and those pollutants using annual arithmetic mean, are not to be exceeded more than once a year. The O_3 standard is attained when the expected number of days per calendar year with maximum hourly average concentrations above the standard is equal to or less than 1.
[c] ppm = parts per million by volume; ppb = parts per billion; µg/m^3 = micrograms per cubic meter.

Table 3.2-2. Federal and State Attainment Status for the Los Angeles County Portion of the South Coast Air Basin

Pollutants	**Federal Classification**	**State Classification**
O_3 (1-hour standard)	—	Nonattainment
O_3 (8-hour standard)	Nonattainment, Extreme	Nonattainment
PM10	Attainment/Maintenance	Nonattainment
PM2.5	Nonattainment	Nonattainment
CO	Attainment/Maintenance	Attainment
NO_2	Attainment/Maintenance	Attainment
SO_2	Attainment	Attainment
Pb	Nonattainment	Attainment

Note that only the Los Angeles County portion of the South Coast Air Basin is nonattainment for NAAQS Pb. The remainder of the Basin is attainment.
Sources: ARB 2013b; EPA 2015; ICF, 2016.

notification of people exposed to a significant health risk, and facility plans to reduce these risks (ARB 2010). AB 2588 requires local air districts like SCAQMD to designate high, intermediate, and low priority categories and report on facilities that may pose a risk to the public.

To date, ARB has identified 21 TACs and adopted EPA's list of hazardous air pollutants as TACs. In August 1998, ARB identified diesel exhaust particulate matter (DPM) emissions as a TAC (ARB 1998). In September 2000, ARB approved a comprehensive diesel risk reduction plan to reduce emissions from both new and existing diesel-fueled engines and vehicles. The goal of the plan was to reduce DPM emissions and the associated health risk by 75 percent by 2010 and by 85 percent by 2020 (ARB 2000).

Local

South Coast Air Quality Management District

SCAQMD has adopted a series of air quality management plans (AQMPs), which are components of the SIP developed to meet the CAAQS and NAAQS in nonattainment areas. These plans require, among other emissions-reducing activities, control technology for existing sources, control programs for area sources and indirect sources, an SCAQMD permitting system that allows no net increase in emissions from any new or modified (i.e., previously permitted) emissions sources, and transportation control measures. The most recent AQMP is the 2012 AQMP, adopted by SCAQMD's Governing Board on December 7, 2012. ARB approved the 2012 AQMP on January 25, 2013, and the plan was submitted to EPA as a revision to the California SIP (ARB 2013a). The 2012 AQMP addresses CAA requirements and includes a 24-hour PM2.5 plan; additional 8-hour O_3 measures, with a vehicle-miles-traveled (VMT) offset demonstration; and a 1-hour O_3 attainment demonstration with VMT offset demonstration. SCAQMD is in the process of developing the 2016 AQMP, which will be primarily focused on addressing the ozone and PM2.5 standards. SCAQMD released the Draft 2016 AQMP for public review in June 2016 and SCAQMD's Governing Board will consider adoption of the Final 2016 AQMP in December 2016.

SCAQMD published the *CEQA Air Quality Handbook* in November 1993[1] to help local governments analyze and mitigate project-specific air quality impacts. This handbook provides standards, methodologies, and procedures for conducting air quality analyses as part of CEQA documents prepared within its jurisdiction. In addition, SCAQMD published two additional guidance documents, *Localized Significance Threshold Methodology for CEQA Evaluations* (2003, revised 2008) and *Particulate Matter (PM) 2.5 Significance Thresholds and Calculation Methodology* (2006). These publications provide guidance for evaluating localized effects from mass emissions during construction. Both were used in the preparation of this analysis (SCAQMD 2006, 2008a).

Through the attainment planning process, SCAQMD develops rules and regulations to address the sources of air pollution in the Basin (SCAQMD 2015a). The majority of emissions sources associated with the Proposed Project are from electricity, generated by facilities associated with the Los Angeles Department of Water and Power (LADWP) and therefore, the Proposed Project is not subject to SCAQMD stationary-source rules, such as Regulation XIII (New Source Review), Rule 1401 (New Source Review of Toxic Air Contaminants), and Rule 431.2 (Sulfur Content of Liquid Fuels). Nevertheless, the Proposed Project is subject to the adopted SCAQMD rules and regulations listed below, including rules regarding the backup generator.

[1] Section updates provided on SCAQMD's website: http://www.aqmd.gov/ceqa/hdbk.html

SCAQMD Rule 402—Nuisance. This rule prohibits the discharge of air contaminants or other material that cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public; endanger the comfort, repose, health, or safety of any such persons or the public; or cause, or have a natural tendency to cause, injury or damage to business or property. Odors are regulated under this rule.

SCAQMD Rule 403—Fugitive Dust. This rule prohibits emissions of fugitive dust from any active operation, open storage pile, or disturbed surface area that remains visible beyond the property line of the emission's source. During construction of the Proposed Project, best available control measures identified in the rule would be required to minimize fugitive dust emissions from earthmoving and grading activities. These measures would include site pre-watering and re-watering as necessary to maintain sufficient soil moisture content.

SCAQMD Rule 1108—Cutback Asphalt. This rule specifies VOC content limits for cutback asphalt, a liquid petroleum product used during road construction activities.

SCAQMD Rule 1470—Requirements for Stationary Diesel-Fueled Internal Combustion and Other Compression Ignition Engines. This rule specifies requirements for stationary diesel engines, including emergency standby generators. It requires owners or operators of emergency standby generators to keep monthly logs of usage, limits maintenance and testing to 20 hours per year, and requires emission rates to not exceed 0.40 grams per brake-horsepower hour (g/bhp-hr).

Southern California Association of Governments

The Southern California Association of Governments (SCAG) is the regional planning agency for Los Angeles, Orange, Ventura, Riverside, San Bernardino, and Imperial counties. SCAG addresses regional issues related to transportation, the economy, community development, and the environment, and is the federally-designated metropolitan planning organization (MPO) for a majority of the region and the largest MPO in the nation. As required by federal and state law, SCAG develops plans pertaining to transportation, growth management, hazardous waste management, housing, and air quality. SCAG data are used in the preparation of air quality forecasts and the consistency analysis included in the AQMP.

City of Los Angeles

The Air Quality Element of the City's General Plan (adopted by City Council on November 24, 1992) specifies goals, objectives, and policies to maintain clean air within the City and achieve consistency with regional air quality planning by SCAQMD and SCAG and to minimize health risks posed by air pollution sources (City of Los Angeles 1992).

The City does not have the authority to directly regulate air quality; however, the City addresses nuisances, including odors. The City has developed a Sewer System Management Plan (SSMP) (2015), which addresses odors generated from sewer gases. The SSMP includes an odor complaint contact number and tracking of occurrences via a geographic information system (GIS) management database, which allows quick identification and visualization of problem areas that can be prioritized for inspection, maintenance, and repairs. The City has a four-pronged approach to odor control: regular maintenance, system-wide treatment, site-specific corrective action, and capital improvement, including new and state-of-the-art odor control facilities. Most odor problems are resolved by regular cleaning or site-specific treatments. The City has also built permanent odor treatment facilities at strategic locations along major interceptors. These new odor facilities capture hydrogen sulfide through the use of fans and treat sewer gases using highly advanced treatment technologies.

3.2.2 Environmental Setting

3.2.2.1 Regional Setting

Regional Climate

The Project Site is within the Los Angeles Basin, which covers approximately 6,745 square miles and is bounded by the Pacific Ocean to the west and south and the San Gabriel, San Bernardino, and San Jacinto Mountains to the north and east. The Basin includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties, in addition to the San Gorgonio Pass area in Riverside County. The terrain and geographical location determine the distinctive climate of the Basin, which is a coastal plain with connecting broad valleys and low hills.

The Basin lies in the semi-permanent high-pressure zone of the eastern Pacific. As a result, the climate is mild and tempered by cool sea breezes. The usually mild climatological pattern is interrupted infrequently by periods of extremely hot weather, winter storms, or Santa Ana winds. The extent and severity of the air pollution problem in the Basin is a function of the area's natural physical characteristics (weather and topography), as well as human-made influences (development patterns and lifestyle). Factors such as wind, sunlight, temperature, humidity, rainfall, and topography all affect the accumulation and dispersion of pollutants throughout the Basin, making it an area of high pollution potential.

Regional Air Quality

The greatest air pollution impacts in the Basin occur from June through September. These are generally attributed to the large amount of pollutant emissions, light winds, and shallow vertical atmospheric mixing. This condition frequently reduces pollutant dispersion, thereby causing elevated air pollution levels. Pollutant concentrations in the Basin vary with location, season, and time of day. O_3 concentrations, for example, tend to be lower along the coast, higher in the near inland valleys, and lower in the far inland areas of the Basin and adjacent desert.

With regards to attainment status, The Los Angeles County portion of the Basin fails to meet national standards for O_3, PM10, PM2.5, and lead and state standards for O_3, PM10, and PM2.5. In addition, the Los Angeles County portion of the Basin is considered a maintenance area for national CO, NO_2, and PM10 standards.

With regards to TACs, SCAQMD has completed ambient air monitoring and evaluation studies in the Basin, called Multiple Air Toxics Exposure Study (MATES). The most recent is the MATES IV study, released to the public in May 2015. The MATES IV study concluded that the average carcinogenic risk throughout the Basin attributed to TACs is approximately 1,023 in one million. About 68.2% of all risk is attributed to diesel particulate matter (DPM) emissions, but DPM showed a 70% reduction compared to MATES III (SCAQMD 2015b).

3.2.2.2 Local Setting

Local Climate

Data from the closest climate monitoring station—Western Regional Climate Center's (WRCC's) Santa Monica Pier Station (approximately 3 miles north of the Project Site)—were used to characterize Project vicinity climate conditions. Over the period of record (1937-2015), summer

high and low temperatures average 71°F and 61°F, while the winter high and low temperatures average 64°F and 50°F, respectively. Rainfall varies widely from year to year, with an annual average of 13 inches, with the majority of rainfall falling between December and March (WRCC 2016a).

The closest wind monitoring station is the Santa Monica Airport wind monitoring station, which is approximately 3 miles north of the Project Site. Wind patterns in the Project vicinity arise primarily from the southwest with an average speed of 6 miles per hour (WRCC 2016a).

Local Air Quality

In order to monitor local air quality, SCAQMD, divides the Basin into air monitoring areas, and maintains a network of air quality monitoring stations. The Project Site is in the Northwest Coastal LA County Monitoring Area (Source Receptor Area [SRA] 2). The monitoring station within SRA 2 is the West Los Angeles-VA Hospital monitoring station (ARB 70091) near Wilshire Boulevard and Sawtelle Boulevard, 5 miles north of the Project Site. Criteria pollutants monitored at the West Los Angeles-VA Hospital monitoring station include O_3, CO, and NO_2.

Because not all criteria pollutants are monitored at the West LA-VA monitoring station, additional monitoring data have been provided from the Los Angeles-Westchester Parkway monitoring station (ARB 70111) and the Compton-700 North Bullis Road monitoring station (ARB 70112). The Los Angeles-Westchester Parkway monitoring station, located 2.5 miles south of the Project Site in SRA 3, is the closest monitoring station to the Project Site and provides additional setting detail, including PM10 data. The Compton-700 North Bullis Road monitoring station, located 16 miles southeast of the Project Site, is the closest monitoring station that monitors PM2.5. Table 3.2-3 shows air quality monitoring data in the project area.

Table 3.2-3. Ambient Background Concentrations from the West Los Angeles-VA Hospital (ARB 70091), Los Angeles – Westchester Parkway (ARB 70111) and Compton – 700 N Bullis Road (ARB 70112) Monitoring Stations

Pollutant Standards	2012	2013	2014
1-Hour Ozone (O_3) - West Los Angeles-VA Hospital (ARB 70091)			
State Maximum Concentration (ppm)	0.093	0.088	0.116
Number of Days Standard Exceeded			
CAAQS 1-hour Standard (> 0.09 ppm)	0	0	1
8-Hour Ozone (O_3) - West Los Angeles-VA Hospital (ARB 70091)			
State Maximum Concentration (ppm)	0.074	0.076	0.095
National Maximum Concentration (ppm)	0.073	0.075	0.094
National Fourth-Highest Concentration (ppm)	0.067	0.065	0.085
National Design Value (ppm)	0.065	0.062	0.067
Number of Days Standard Exceeded			
CAAQS 8-hour Standard (> 0.070 ppm)	0	0	4
NAAQS 8-hour Standard (> 0.075 ppm)	1	1	6
Carbon Monoxide (CO) - West Los Angeles-VA Hospital (ARB 70091)			
Maximum Concentration 8-hour Period (ppm)	1.15	N/A	N/A
Number of Days Standard Exceeded			
NAAQS 8-hour Standard (≥ 9 ppm)	0	N/A	N/A
CAAQS 8-hour Standard (≥ 9.0 ppm)	0	N/A	N/A

Pollutant Standards	2012	2013	2014
Nitrogen Dioxide (NO_2) - West Los Angeles-VA Hospital (ARB 70091)			
Maximum National 1-hour Concentration (ppm)	0.0613	0.0512	0.0639
Maximum State 1-hour Concentration (ppm)	0.061	0.051	0.063
Annual Average Concentration (ppm)	N/A	N/A	N/A
Number of Days Standard Exceeded			
CAAQS 1-Hour Standard (0.18 ppm)	0	0	0
NAAQS 1-Hour Standard (100 ppb)	0	0	0
Suspended Particulates (PM10) - Los Angeles – Westchester Parkway (ARB 70111)			
Maximum State 24-hour Concentration (µg/m^3)	30.0	37.0	45.0
Maximum National 24-hour Concentration (µg/m^3)	31.0	38.0	46.0
State Annual Average Concentration (µg/m^3)	21	21	22
Number of Days Standard Exceeded			
CAAQS 24-hour Standard (> 50 µg/m^3)	0	0	0
NAAQS 24-hour Standard (> 150 µg/m^3) *(Estimated)*	0	0	0
Suspended Particulates (PM2.5) - Compton – 700 N Bullis Road (ARB 70112)			
Maximum National 24-hour Concentration (µg/m^3)	51.2	52.1	35.8
24-hour Standard 98th Percentile (µg/m^3)	30.3	24.3	30.9
National Annual Average Concentration (µg/m^3)	11.6	11.9	12.6
State Annual Average Concentration (µg/m^3)	11.7	N/A	N/A
Number of Days Standard Exceeded			
NAAQS 24-hour Standard (> 35 µg/m^3)	1	1	1

ppm = parts per million; ppb = parts per billion; µg/m^3 = micrograms per cubic meter; NA = data not available.
Sources: ARB 2015b; EPA 2015c; ICF, 2015.

Monitoring data show the following trends for pollutant concentrations: the 1-hour O_3 state standard was exceeded one time at the West LA-VA station; the 8-hour O_3 federal and state standards were exceeded multiple times at the West LA-VA station; and the 24-hour PM2.5 federal standard was exceeded once per year at the Compton station. There were no violations of the PM10 federal standard, CO federal or state standards, or NO_2 state standard. In general, pollutant concentrations are lower in the Project vicinity compared to other inland parts of the Basin due to the limited amount of nearby industrial uses in addition to the presence of regular coastal breezes that disperse pollutants.

3.2.2.3 Local Health Risk

According to SCAQMD inhalation cancer risk data from MATES IV, the Project area is within a cancer risk zone of approximately 747 in one million (SCAQMD 2016). For comparison, the cancer risk shown in the previous MATES study, MATES III, showed an average cancer risk of approximately 749 in one million. Overall, emissions have decreased within the Basin and air quality has improved since MATES III (SCAQMD 2015c).

3.2.2.4 Sensitive Receptors and Locations

SCAQMD defines sensitive receptor locations as residential, commercial, and industrial land use areas as well as other locations where sensitive populations may be located. Other sensitive receptor locations include schools, hospitals, convalescent homes, day care centers, and other locations where children, chronically ill individuals, or other sensitive persons could be exposed (SCAQMD 2005a).

Sensitive receptors within the Project vicinity include the surrounding residences, particularly the multi-family residences directly to the north, west, and east of the Proposed Project Site. The closest sensitive receptor is the multi-family residential complex to the north of the Project Site along Canal Court, which abuts the Project Site boundary. Other sensitive receptors include an elementary school, an elderly housing facility, and a convalescent home that are within the Project vicinity.

3.2.2.5 Odors

As discussed in Chapter 2 (Project Description), the existing VPP is equipped with an exhaust fan that discharges vapors through an existing stack, but field investigation of the ventilation fan shows that the flange that connects the fan to the dispersion stack is displaced, and odors can exit through the gap at the joint. Also, the use of aboveground rental pumps necessary during repairs to the existing pumps have been known to temporarily produce odors in the Project area.

3.2.2.6 Naturally Occurring Asbestos

Disturbance of rock and soil that contains naturally-occurring asbestos (NOA can result in consequent exposure to the public. Asbestos most commonly occurs in serpentine rock, and its parent material, ultramafic rock. Construction activities in areas known to contain ultramafic rocks may expose workers and the general public to NOA. According to the California Department of Conservation, the Basin does not contain NOA, except for Catalina Island where small ultramafic rock occurrences are present (SCAQMD 2005c).

3.2.3 Environmental Impact Analysis

3.2.3.1 Methodology

Construction Emissions

Construction of the Proposed Project would result in the short-term generation of criteria pollutant and TAC emissions. Mass daily combustion exhaust, fugitive dust (PM10 and PM2.5), and fugitive off-gassing paving emissions were estimated using SCAQMD's California Emissions Estimator Model (CalEEMod), version 2013.2.2 (SCAQMD 2013). CalEEMod estimates criteria pollutant and greenhouse gas (GHG) emissions associated with construction and operation of land use development projects. Each phase of construction would result in combustion exhaust emissions from on-site construction equipment, haul truck travel, material deliveries, and construction workers' commutes. The site preparation and grading/excavation phases would include fugitive dust and hauling emissions associated with up to 10,000 cubic yards of soil and asphalt removal, and it is assumed that the materials would be hauled off-site in trucks with a capacity to carry 7 cubic yards. Approximately 7,700 cubic yards would be stockpiled off-site and, once tested, approximately half of the volume would be brought to a local landfill, such as Sunshine Canyon Landfill located in Los Angeles for permanent storage. Construction equipment for each phase of construction was provided by the Project designer (Arcadis), with the exception that CalEEMod defaults were used for the architectural coating phase, which is based on Project acreage and building size. It was assumed that up to 20 workers would be required on the site for the foundation and building construction period. Construction is anticipated to begin in March 2018 and would take approximately 24 months to complete. Table 3.2-4 shows a summary of construction assumptions that were used to estimate construction-period emissions.

Table 3.2-4. Summary of Construction Assumptions

Construction Activity	Assumption
Construction Start Date	March 2018
Construction Duration	24 months
Equipment	Air Compressors Cement and Mortar Mixers Crane Concrete/Industrial Saws Forklifts Graders Pavers Rollers Excavators Tractors/Loaders/Backhoes Rubber Tired Dozers Bore/Drill Rigs Plate Compactors
Initial Off-Haul Excavation Materials	10,000 cubic yards
Stockpiled at Laydown Area 3 (Culver City)	*7,700 cubic yards (1,485 truck round trips)*
Stockpiled at Laydown Area 1	*2,300 cubic yards (444 truck round trips)*
Excavation Materials Returned to Site from Laydown Area 3	3,850 cubic yards (743 truck round trips)
Excavation Materials Sent to a Local Landfill from Laydown Area 3	3,850 cubic yards (743 truck round trips)
Due to the narrow street widths in the project vicinity, it was assumed that trucks with a capacity of 7 cubic yards would be used. This analysis also assumes a 35% allowance for soil expansion and less-than-full loads. Additional details related to construction assumptions are included in Appendix B of this EIR.	

Regarding localized effects, SCAQMD's localized significance threshold (LST) methodology was developed to aid in the analysis of construction associated with land use development projects. LSTs represent the maximum emissions from a project that are not expected to cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standard, and are developed based on the ambient concentrations of that pollutant for each source receptor area and distance to the nearest sensitive receptor. The LST methodology directs analyses to focus on emissions from mobile construction equipment (i.e., excavators, graders, backhoes, generators, etc.) and stationary sources (i.e., natural gas furnaces, emergency generators, etc.). The LST methodology and lookup tables are not designed to evaluate localized impacts from mobile sources traveling over roadways. Therefore, the LST analysis only includes those emissions that would occur on-site, and does not include emissions from construction vehicle travel on public roadways.

In modeling emissions, it was assumed that the site preparation and grading phases would occur separately and that the building construction, asphalt paving, and architectural coatings phases would occur concurrently. For the purposes of this analysis, fugitive dust emissions assume compliance with SCAQMD Rule 403. According to SCAQMD guidance, Rule 403 would reduce fugitive

dust emissions by 61 percent by watering three times per day (SCAQMD 2013). Emissions are presented at the daily time scale (i.e., pounds per day [lbs/day]) and compared with SCAQMD's thresholds discussed in Section 3.2.4.2, below. All emissions calculation worksheets and air quality modeling output files are provided in Appendix B of this EIR.

Although diesel trucks would be used during the construction period, the vast majority of haul trips would be performed during the site preparation and grading/excavation phases, limited to approximately 6 months. This is shorter than the 30-year exposure assumed for residential cancer risks in SCAQMD guidance (SCAQMD 2015). Consequently, cancer risks related to the toxic air contaminants released during the construction period have not been quantified.

Odors are addressed in a qualitative manner, identifying the elements of Project construction or operation that have the potential to result in objectionable odors in the Project vicinity.

Operational Emissions

CalEEMod was also used to quantify impacts related to Project operation, including trips by employees, who would staff the plant 24 hours per day, 7 days a week, with two employees on-site per 8-hour shift. In addition, the modeling accounted for the energy use of the operational facility.

Project operation would involve occasional trips from those performing maintenance work on the submersible pumps, which would occur at least once annually. In addition, Project implementation may also require the occasional use of a 24-kW diesel generator to be used to provide backup power to VAPP in the event of loss of power. Due to their infrequency, maintenance activities and use of the generator were not quantified.

Regarding localized effects, SCAQMD's LST methodology was developed to aid in the analysis of operations associated with land use development projects. It directs analyses to focus on criteria pollutant emissions from stationary sources (i.e., natural gas furnaces, emergency generators, etc.) and mobile equipment (i.e., forklifts) operating on-site. The LST methodology and lookup tables are not designed to evaluate localized impacts from mobile sources traveling over roadways or to analyze the effects of TACs on nearby receptors. Therefore, the LST analysis only includes those criteria pollutant emission sources that would occur on-site, and does not include emissions from motor vehicles traveling on roadways. However, to provide a conservative analysis, the LST analysis does include emissions from on-site truck activity associated with idling on-site. Emissions from on-site sources would occur on the entire site. Although the site is smaller than one acre, a one-acre site is assumed herein, as this is the smallest site size for which LST thresholds are published. Further, because emissions would occur throughout the entire site, receptor distance was taken from the center of the Project Site, as opposed to the edges for the construction site. Therefore, a 25-meter (82 feet) receptor distance was utilized for the operational analysis herein, which is the shortest distance available in SCAQMD's LST methodology. Because Project operation would result in a minimal increase in the number of vehicle trips and would not increase congestion or reduce vehicle speeds at an intersection or roadway within a ¼-mile distance of a sensitive receptor, the potential for localized exceedances of the California 1-hour or 8-hour CO standard is considered negligible and is not addressed below. All emissions calculation worksheets and air quality modeling output files are provided in Appendix B of this EIR.

As discussed above, based on the limited number of diesel truck trips associated with Project maintenance activities and the infrequency of use of the 24-kW diesel generator, the health effects of toxic air contaminants, including DPM, were not quantified. Odors are addressed in a qualitative

manner, identifying the elements of Project construction and operation that have the potential to result in objectionable odors in the Project vicinity.

Cumulative Impacts

In assessing cumulative construction impacts, the *L.A. CEQA Thresholds Guide* recommends the analysis review the related projects list and identify those projects with construction schedules that would coincide with the schedule of the Proposed Project. The *Thresholds Guide* recommends estimating the potential emissions from the related projects that would occur during construction of the Proposed Project, based on available information and, using the methodology above, determine the combined emissions for the Proposed and related projects.

In assessing cumulative operational impacts, the *L.A. CEQA Thresholds Guide* recommends the analysis review the list of related projects to identify those that would have pollutant or odor emissions. Based on the related projects, the analysis will determine the potential impacts of all such projects, together with the Proposed Project.

Similarly, SCAQMD recommends that Proposed Project be examined within the scope of the existing setting and that the examination take into account new and planned similar and nearby projects (SCAQMD 1993). Moreover, SCAQMD recommended the cumulative impact discussion consider consistency with the VMT and emission reduction targets and measures within the most recent AQMP (SCAQMD 1993). Further, SCAQMD thresholds have been established to support the AQMP and ensure attainment of the NAAQS and CAAQS. Therefore, an exceedance of SCAQMD threshold levels must be considered a significant cumulative impact and an adverse cumulative consequence.

The discussion below identifies potential Project impacts and the measures that would be required to mitigate impacts that are found to be potentially significant.

3.2.3.2 Screening Analysis

As noted in Section Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study) of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis are addressed in this EIR.

3.2.3.3 Thresholds of Significance

State Significance Thresholds

The criteria used to determine the significance of an impact on air quality are based on Appendix G of the CEQA Guidelines (as well as those identified in the *L.A. CEQA Thresholds Guide* and the thresholds established by SCAQMD, which are discussed below under Regional and Local Significance Thresholds). According to Appendix G, a project would normally have a significant impact on air quality if it could result in:

- **AQ-1.** Conflict with or obstruct implementation of the applicable air quality plan;
- **AQ-2.** Violate any air quality standard or contribute substantially to an existing or projected air quality violation;

- **AQ-3.** Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors);
- **AQ-4.** Expose sensitive receptors to substantial pollutant concentrations; or
- **AQ-5.** Create objectionable odors affecting a substantial number of people.

Regional and Local Significance Thresholds

Construction Emissions

As stated in the *L.A. CEQA Thresholds Guide* (2006), the City has not adopted a citywide significance threshold for construction emissions. Rather, it is the responsibility of the lead City department to determine the appropriate standards; in the absence of a department policy, the *Thresholds Guide* defers to SCAQMD's *CEQA Air Quality Handbook* and/or EPA's AP-42 emission factors and assessment methodologies. The *Thresholds Guide* reprints guidance from the *CEQA Air Quality Handbook* to assist in the evaluation of Project impacts, as determined appropriate by each lead agency (SCAQMD 1993). Project-related factors to be used in a case-by-case evaluation of significance include the following factors (B.1. Construction Emissions):

- Combustion Emissions from Construction Equipment:
  - Type, number of pieces and usage for each type of construction equipment;
  - Estimated fuel usage and type of fuel (diesel, natural gas) for each type of equipment; and
  - Emission factors for each type of equipment.
- Fugitive Dust
- Grading, Excavation, and Hauling
  - Amount of soil to be disturbed on-site or moved off-site;
  - Emission factors for disturbed soil;
  - Duration of grading, excavation and hauling activities;
  - Type and number of pieces of equipment to be used; and
  - Projected haul route.
- Heavy-Duty Equipment Travel on Unpaved Roads
  - Length and type of road;
  - Type, number of pieces, weight and usage of equipment; and

    Type of soil.
- Other Mobile Source Emissions
  - Number and average length of construction worker trips to Project Site, per day; and
  - Duration of construction activities.

In addition, SCAQMD's *CEQA Air Quality Handbook* contains a Screening Table for Construction based on construction emissions occurring over a three-month (quarterly) period (*CEQA Air Quality*

Handbook 1993*:* pages 6-12). Given SCAQMD's regulatory role in the Basin, the significance thresholds and analysis methodologies established by SCAQMD are relied upon to make determinations regarding air quality impacts. The significance thresholds and analysis methodologies outlined in SCAQMD's *CEQA Air Quality Handbook*, *Localized Significance Threshold Methodology for CEQA Evaluations*, and *Particulate Matter (PM) 2.5 Significance Thresholds and Calculation Methodology* (2006) guidance documents were used in evaluating Project impacts. Specifically, SCAQMD construction and mass emissions thresholds identified in Table 3.2-5 were used for the regional assessment of criteria pollutants herein.

Table 3.2-5. SCAQMD Significance Thresholds (pounds per day)

	VOC	NO_X	CO	SO_2	PM10	PM2.5	Pb[a]
Construction							
Localized Significance Thresholds [b]	--	103	562	--	4.0	3.0	--
Regional Significance Thresholds	75	100	550	150	150	55	3
Operations							
Localized Significance Thresholds [b]	--	103	562	--	1.0	1.0	--
Regional Significance Thresholds	55	55	550	150	150	55	3

[a] The Proposed Project would result in no lead emissions during construction or operations. As such, lead emissions are not evaluated herein.

[b] Localized thresholds for construction and operations are based on a 1-acre Project Site and 25-meter distance to receptors within SRA 2. SCAQMD has not developed LSTs for VOC, SO_2, or Pb emissions.

Source: SCAQMD 2015e, 2015d; ICF, 2016.

With respect to localized emissions, SCAQMD has developed LSTs and mass rate look-up tables to help public agencies analyze the Project-related effects of pollutants on nearby receptors. The LSTs are based on the size or total area of the emissions source, the ambient air quality in each SRA where the emissions sources are located, and the distance to nearby sensitive receptor locations. The Project Site encompasses approximately 0.25 acre within the Northwest Los Angeles County Coastal Monitoring Area (SRA 2). Although the site is located adjacent to multi-family residences and the site is smaller than 1 acre, the analysis of impacts is based on a 25-meter receptor distance and a 1-acre site, the most conservative LSTs developed by SCAQMD.

Operational Emissions

According to the *L.A. CEQA Thresholds Guide* (2006) a Proposed Project would normally have a significant impact from project operations if any of the following would occur (B.2. Operational Emissions):

- Operational emissions exceed 10 tons per year of volatile organic gases or any of the daily thresholds as identified in SCAQMD's *CEQA Air Quality Handbook*;
- Either of the following conditions would occur at an intersection or roadway within one-quarter mile of a sensitive receptor:
    - The Proposed Project causes or contributes to an exceedance of the California 1-hour or 8-hour CO standards of 20 or 9.0 parts per million (ppm), respectively; or

- The incremental increase due to the project is equal to or greater than 1.0 ppm for the California 1-hour CO standard, or 0.45 ppm for the 8-hour CO standard.

- The Proposed Project creates an objectionable odor at the nearest sensitive receptor.

Toxic Air Contaminants

According to the *L.A. CEQA Thresholds Guide* (2006), the determination of significance related to Toxic Air Contaminants shall be made on a case-by-case basis, considering the following factors (B.3. Toxic Air Contaminants):

- The regulatory framework for the toxic material(s) and process(es) involved;
- The proximity of the toxic air contaminants to sensitive receptors;
- The quantity, volume and toxicity of the contaminants expected to be emitted;
- The likelihood and potential level of exposure; and
- The degree to which project design will reduce the risk of exposure.

Additionally, consistent with SCAQMD guidelines, for the purposes of this EIR, the Proposed Project would have a significant impact from TACs if:

- Project-related emission sources, both stationary and mobile, emit carcinogenic or TACs that individually or cumulatively exceed the maximum incremental cancer risk of 10 in 1 million (1.0 x 10-5) or an acute or chronic Hazard Index of 1.0 (SCAQMD 2005b, 2015c).
- Hazardous materials associated with on-site stationary sources result in an accidental release of air toxic emissions or acutely hazardous materials, posing a threat to public health and safety (SCAQMD 1993).

Asbestos

SCAQMD also recommends a discussion of naturally occurring asbestos when siting sensitive land uses, particularly school sites. If a project would be located in an area moderately likely to contain NOA, then the impact shall be considered potentially significant without implementation of measures to reduce potential NOA exposure and resultant human health effects. Accordingly, NOA impacts in this analysis are considered significant if the project is located in an area moderately likely to contain NOA and fails to comply with all applicable NOA control measures. As discussed above, the Basin does not contain NOA, except for Catalina Island where small ultramafic rock occurrences are present (SCAQMD 2005c). **Thus, no impacts related to NOA would occur as a result of Project implementation, and no further discussion is required.**

3.2.3.4 Construction Impacts

The analysis below describes the temporary direct and indirect impacts on air quality anticipated as a result of the Proposed Project during construction.

AQ-1. Would the Project conflict with or obstruct implementation of the applicable air quality plan?

Construction activities are considered consistent with the AQMP if they are in compliance with SCAQMD rules, such as Rule 403, which the Proposed Project would be. The Proposed Project would

not conflict with or obstruct implementation of the AQMP and therefore, **impacts would be less than significant and no mitigation measures are required.**

AQ-2. Would the Project violate any air quality standard or contribute substantially to an existing or projected air quality violation or expose sensitive receptors to substantial pollutant concentrations?

The Proposed Project would contribute to regional air pollutant emissions during short-term construction. An analysis of the construction-related effects of the Proposed Project is presented below.

Construction of the Proposed Project has the potential to create air quality impacts through the combustion emissions from heavy-duty construction equipment, construction workers' vehicle trips, material deliveries, and trips by heavy-duty haul trucks. In addition, earthwork activities would result in fugitive dust emissions, and emissions from grading, excavation and hauling on paved and unpaved roads. Paving operations would release VOCs from off-gassing (release of airborne particles). Construction emissions can vary substantially from day to day, depending on the level of activity, the specific type of operation, and, for dust, the prevailing weather conditions. The assessment of construction air quality impacts considers each of these potential sources and accounts for the factors identified in the thresholds that must be considered (detailed assumptions for each of these factors used in the analysis are presented in Appendix B of this EIR). Fugitive PM10 and PM2.5 emissions estimates take into account compliance with SCAQMD Rule 403.

Regional construction-related emissions are shown in Table 3.2-6. The construction analysis, which utilized CalEEMod, assumes that the site preparation and grading phases would occur separately and that the building construction, asphalt paving, and architectural coatings phases would occur concurrently. The maximum day for NO_X, CO, PM10, and PM2.5 emissions are expected to occur during the grading phase. The maximum day for VOC/ROG emissions is expected to occur when the building construction/paving/coatings phases occurs. As shown in Table 3.2-6, maximum daily Project-related criteria pollutant emissions would not exceed SCAQMD construction-period regional thresholds for any pollutant. Consequently, the impact of construction-related emissions on regional air quality would not violate any air quality standard or contribute substantially to an existing or projected air quality violation and as such, **impacts would be less than significant and no mitigation measures are required.**

Project construction would emit localized pollutants through the on-site use of heavy-duty construction equipment as well as fugitive dust from ground-disturbing activities. These localized emissions could expose nearby sensitive receptors to substantial pollutant concentrations.

With regards to localized emissions, localized construction-related emissions are shown in Table 3.2-7. The maximum day for VOC and SO_X emissions are expected to occur when building construction, paving, and architectural coatings would potentially overlap. The maximum day for NO_X, CO, PM10, and PM2.5 emissions is expected to occur during the grading phase. As shown in Table 3.2-7, localized emissions during construction would exceed the LST for PM10. With the implementation of **Mitigation Measure AQ-1**, which would require the use of Tier 3 construction equipment, emissions would be below the LST for PM10. Construction-period emissions with the implementation of **Mitigation Measure AQ-1** are shown in Table 3.2-8. **Consequently, the impact of construction-related emissions on local air quality would not violate any air quality standard or contribute substantially to an existing or projected air quality violation and as such, would be less than significant with the implementation of Mitigation Measure AQ-1.**

Table 3.2-6. Estimate of Regional Construction Emissions (pounds per day)

Construction Phase	VOC	NO_X	CO	SO_X	PM10	PM2.5
Site Preparation	2	19	12	< 1	1	1

Diesel trucks would be used during the construction period, resulting in emissions of TACs, particularly DPM. Although DPM would be emitted during the construction period, the period of exposure to residents neighboring the site would be limited to approximately 6 months when most of the diesel trucks hauling materials would be used. This is shorter than the 30-year exposure assumed for residential cancer risks in SCAQMD guidance (SCAQMD 2015). Given that neither the regional nor the localized emissions thresholds would be exceeded with the implementation of **Mitigation Measure AQ-1**, as shown in Tables 3.2-6 through 3.2-8, above, emissions emanating from the Project Site would not violate any air quality standard. **In addition, emissions would not contribute substantially to an existing or projected air quality violation or expose sensitive receptors to substantial pollutant concentrations and as such, impacts would be less than significant.**

AQ-3. Would the Project result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is non-attainment under an applicable federal or state ambient air quality standard?

As discussed above, the Basin is a federal nonattainment area for ozone, PM2.5, and Pb and state nonattainment area for ozone, PM10, and PM2.5. As shown in Table 3.2-6, emissions of regional pollutants during the construction-period would not exceed SCAQMD thresholds. Given that SCAQMD's thresholds were developed to ensure that impacts at the Project level would not hinder regional attainment, the Proposed Project would not result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is nonattainment. Furthermore, construction-period emissions would be short-term in nature and would occur over 24 months, with no long-term construction-related emissions. **Impacts would be less than significant, and no mitigation measures are required.**

AQ-4. Would the Project expose sensitive receptors to substantial pollutant concentrations?

As shown in Table 3.2-8, construction of the Proposed Project, with the implementation of **Mitigation Measure AQ-1**, would not result in an exceedance of LSTs such that significant impacts on sensitive receptors would occur. The TAC exposure period for sensitive receptors would be substantially less than the 30-year exposure assumed for residential cancer risks in SCAQMD

guidance (SCAQMD 2015). **Therefore, impacts related to sensitive receptors during the construction period would be less than significant.**

AQ-5. Would the Project create objectionable odors affecting a substantial number of people?

During the construction period, site preparation and excavation activities could involve the short-term generation of odors in the vicinity of the Project, mostly related to diesel exhaust from construction equipment. No odors during the connection of the diversion structure to the Coastal Interceptor Sewer located within the Grand Canal or while testing the three submersible pumps are expected to occur, since these activities would occur underground within the sealed valve and metering vault.

During construction of the coffer dam within the Grand Canal, sediment that contains organic material would be extracted which could result in odors when removed from the ground if not properly handled. Once these materials are removed, they would be temporarily stored in Laydown Areas 1 and 3. Various odors may be emitted from the sediment piles during construction that may impact the sensitive receptors in the Project area. However, best management practices will be used to address any potential odors. During the dewatering process, there could be some localized odor when the dewatered dredge material kept onsite on Laydown Area 1 and when it is transferred from the site to Laydown Area 3 via haul trucks. Since the haul truck trailers would be lined to prevent incidental seepage and covered during transport, significant odor impacts are not expected to occur during the handling and transportation of dewatered dredge material. As such, construction odors not result in a **less-than-significant impact and no mitigation measured are required**.

Implementation of the following best management practices would help ensure that potential odors emitted during construction activity would be contained and dispersed to minimize any odor impacts:

- A methodology for phased or staged operations to minimize the amount of sediment stored locally.
- Monitoring with a field olfactometer may occur to establish threshold levels at which additional measures must be incorporated to limit total odors.
- Utilization of lime stabilization (or similar technology) may be used to speed the dewatering process for the sediment layer which contains organic material. Lime enables the contractor to raise the pH level to 12 to contain odors and suppress microbiological decay of the organic material to objectionable gas products. Procurement and local storage of an oxidizing chemical that can be applied in liquid form to treat stored sediment, if needed.
- Displaying signage with the on-site construction supervisor's contact information for area residents to phone in odor complaints.

3.2.3.5 Operational Impacts

AQ-1. Would the Project conflict with or obstruct implementation of the applicable air quality plan?

Criteria for determining consistency for the AQMP are defined in the *CEQA Air Quality Handbook* (SCAQMD 1993). There are two key indicators of consistency:

Consistency Criteria No. 1: ***Whether the project will not result in an increase in the frequency or severity of existing air quality violations or cause or contribute to new violations, or delay timely attainment of air quality standards or the interim emission reductions specified in the AQMP*****.**

Consistency Criterion No. 1 refers to violations of NAAQS and CAAQS. SCAQMD recommends an air quality modeling analysis be performed to identify Project impacts. In order to be found consistent with Consistency Criterion No. 1, the analysis will need to demonstrate that Project emissions will not increase the frequency or severity of existing violations or cause or contribute to new violations. As discussed above, Project construction (Table 3.2-6 through Table 3.2-8) and operation (Table 3.2-9, and Table 3.2-10) would result in emissions that would not exceed regional and localized thresholds crafted to bring the area into attainment (regional thresholds) and to ensure no violations of NAAQS and CAAQS occur locally (localized thresholds). Therefore, the Project complies with Consistency Criterion No. 1.

Table 3.2-9. Estimate of Regional Operational Emissions (pounds per day)

Operational Element	VOC	NO_X	CO	SO_X	PM10	PM2.5
Area	< 1	<1	<1	<1	<1	<1
Energy	< 1	< 1	< 1	< 1	< 1	< 1
Mobile	< 1	< 1	< 1	< 1	< 1	< 1
Maximum Daily Emissions	**< 1**	**< 1**	**< 1**	**< 1**	**< 1**	**< 1**
SCAQMD Regional Operational Threshold	75	100	550	150	150	55
Exceed Significant Threshold?	**No**	**No**	**No**	**No**	**No**	**No**

Exceed Significant Threshold?	N/A	**No**	**No**	N/A	**No**	**No**

N/A: Not applicable; SCAQMD has no localized significance thresholds for VOC or SO_X
Source: CalEEMod modeling by ICF 2016 (Appendix B of this EIR).

Consistency Criteria No. 2: ***Whether the project will exceed the assumptions in the AQMP or increments based on the year of project build-out and phase.***

SCAQMD is required, pursuant to the CAA, to reduce emissions of criteria pollutants for which the Basin is in nonattainment status. SCAQMD's most recent plan to achieve air quality standards is the 2012 AQMP, adopted by SCAQMD's Governing Board on December 7, 2012. The 2012 AQMP outlines a comprehensive control strategy to meet the requirement for expeditious progress toward

attainment of the 24-hour PM2.5 NAAQS in 2014 through all feasible control measures. The 2012 AQMP also includes specific measures for implementing the O_3 strategy from the 2007 AQMP and attaining the 8-hour ozone standard by 2023 (SCAQMD 2013).

The AQMP strategies are based, in part, on regional population, housing, and employment projections prepared by the region's cities and counties. In essence, if a project is consistent with applicable planning documents, then the project is consistent with the AQMP. The Proposed Project is subject to the City of Los Angeles General Plan. Among the components of the General Plan, the Framework Element discusses the goals, objectives, and policies with respect to wastewater, which include the following:

- Goal 9A: Adequate wastewater collection and treatment capacity for the City and in basins tributary to City-owned wastewater treatment facilities.
    - Objective 9.2: Maintain the wastewater collection and treatment system, upgrade it to mitigate current deficiencies, and improve it to keep pace with growth as measured by the City's monitoring and forecasting efforts.
        - Policy 9.2.2: Maintain wastewater treatment capacity commensurate with population and industrial needs.
        - Policy 9.2.4: Continue to implement programs to upgrade the wastewater collection system to mitigate existing deficiencies and accommodate the needs of growth and development.

The Proposed Project is consistent with the wastewater goals, objectives, and policies identified in the Framework Element of the General Plan. The Bureau of Engineering has programmed the Proposed Project as part of its Wastewater – Collection System Program (City of Los Angeles 2016).

Pursuant to SCAQMD guidelines, because the Project would be consistent with the governing land use document, which is the City's General Plan, the Proposed Project is considered consistent with the region's AQMP. Therefore, the Project complies with Consistency Criterion No. 2. As such, because the Project complies with the applicable plans and associated goals, objectives, and policies, the Project would not increase violations or lead to new violations and Project-related emissions accounted for in the AQMP, developed to bring the Basin into attainment status for all nonattainment pollutants and precursors thereof. Therefore, impacts are considered **less than significant; no mitigation measures are required.**

AQ-2. Would the Project violate any air quality standard or contribute substantially to an existing or projected air quality violation or expose sensitive receptors to substantial pollutant concentrations?

Once operational, the Proposed Project would result in the long-term generation of criteria pollutant emissions associated with commute trips of employees working at the site, natural gas combustion for space and heating, and area sources associated with consumer products (cleaning supplies, kitchen aerosols, cosmetics, toiletries), architectural coatings, landscaping of the Open Space area, as well as periodic backup generator testing. Operations-related emissions are shown in Table 3.2-7 and indicate that maximum daily Project-related criteria pollutant emissions would not exceed SCAQMD operations-period thresholds for any pollutant. Consequently, the impact of operations-related emissions would be **less than significant; no mitigation measures are required.**

As shown in Table 3.2-8, localized emissions during operations would not exceed the appropriate LSTs for the Project with the implementation of **Mitigation Measure AQ-1**. Consequently, the impact of operations-related localized emissions **would be less than significant; no mitigation measures are required.**

SCAQMD's *CEQA Air Quality Handbook* recommends an evaluation of CO standards when volume-to-capacity (V/C) ratios at affected intersections or roadways are increased by 2 percent or more at intersections with a level of service (LOS) of C or worse (SCAQMD 1993). As noted in the Project Description (see Chapter 2 of this EIR), two employees would be required for Project operation at any given time for a total of 6 employees per 24-hour day. Thus, the 6 regular round trips associated with the Proposed Project would not increase V/C ratios such that an exceedance of CO standards would occur since these would be minor in nature and would not exceed an established traffic threshold. Therefore, the Proposed Project would not cause or contribute to an exceedance of the California 1-hour or 8-hour CO standards of 20 or 9.0 parts per million (ppm) or result in an incremental increase due to the Project is equal to or greater than 1.0 ppm for the California 1-hour CO standard or 0.45 ppm for the 8-hour CO standard. Consequently, the impact of operations-related CO emissions would be **less than significant; no mitigation measures are required.**

As shown in Table 3.2-7, operational emissions of VOC would be less than 1 pound per day, which is below the 10-ton annual threshold as identified in SCAQMD's *CEQA Air Quality Handbook* (SCAQMD 1993).

Emissions of TAC, particularly DPM, would likely be released during Project operation associated with maintenance vehicles and equipment as well as through the emergency use and testing of the diesel-powered backup generator. Maintenance and inspection activities would be conducted on an as-needed basis, assumed to be at least once per year. The generator would serve as back-up power in the event of power loss. Due to the infrequency of maintenance activities and generator use, substantial emissions of TACs are not anticipated and would be short-term in duration. Thus, operational impact emissions would be **less than significant; no mitigation measures are required.**

AQ-3. Would the Project result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard?

As discussed above, the Basin is a federal nonattainment area for ozone, PM2.5, and Pb and state nonattainment area for ozone, PM10, and PM2.5. As shown in Table 3.2-7, emissions of regional pollutants would not exceed SCAQMD thresholds. Given that SCAQMD's thresholds were developed to ensure that impacts at the Project level would not hinder regional attainment, the Project would not result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is nonattainment. Therefore, regional pollutant emission impacts would be **less than significant; no mitigation measures are required.**

AQ-4. Would the Project expose sensitive receptors to substantial pollutant concentrations?

As shown in Table 3.2-9, operation of the Proposed Project would not result in an exceedance of LSTs such that significant impacts on sensitive receptors would occur. With the exception of the infrequent use of the back-up diesel-powered generator, localized TAC emissions would be minimal during project operation. Therefore, operational impacts related to sensitive receptors would be **less than significant; no mitigation measures are required.**

AQ-5. Would the Project create objectionable odors affecting a substantial number of people?

According to the ARB and SCAQMD's *CEQA Air Quality Handbook*, land uses associated with odor complaints typically include agricultural uses, wastewater treatment plants, food processing plants, chemical plants, composting areas, refineries, landfills, dairies, and fiberglass molding facilities. Although the Proposed Project does not treat wastewater, wastewater is pumped at the site within enclosed pipe and associated underground facilities, and thus the Project has the potential to generate odors.

The existing VPP is equipped with an exhaust fan that discharges vapors through an existing stack and field investigation of the ventilation fan shows that the flange that connects the fan to the dispersion stack is displaced, and odors can exit through the gap at the joint. To remedy this, the fan and flanges would be replaced with compatible equipment as a component of the Proposed Project. In addition, a slide gate at the entrance to the VAPP wet well (where the three submersible pumps would be located) from the influent pipe would be installed to deter odors. Any odors in the piping would therefore be confined to that system. When the VAPP is in operation, the head spaces of the wet wells would be linked by the 66-inch sewer, and the exhaust fan would be able to service the entire system. Given that the Proposed Project would eliminate the existing gap between the existing fan and the dispersion stack, nuisance odors from the existing VPP and Proposed Project would improve. Also, because the Proposed Project would replace rental aboveground pumps that have been known to produce odors in the Project vicinity with underground facilities, the Proposed Project would result in an improvement in odors. Furthermore, the Proposed Project adds redundancy and reliability to the system, thereby reducing the risk of emergency discharges of sewage directly into the Grand Canal and Ballona Lagoon or overflows into the surrounding street network during periods of wet weather, which could create objectionable odors.

Based on the elimination of the gap between the fan and the dispersion stack, replacement of temporary aboveground pumps with underground facilities, and the increased reliability to reduce emergency risks, the Proposed Project is expected to result in improvements related to odors. Therefore, operation of the Proposed Project would not create objectionable odors affecting a substantial number of people, and impacts would be **less than significant; no mitigation measures are required.**

3.2.4 Mitigation Measures

The following mitigation measure would be implemented to reduce impacts related to the construction-period of the PM10 LST. With the implementation of mitigation, impacts would be less than significant.

MM AQ-1. All off-road diesel-powered construction equipment greater than 50 horsepower will meet Tier 3 emission standards. All construction equipment will be outfitted with ARB best available control technology devices. Any emissions-control device used by the contractor will achieve emissions reductions that are no less than what could be achieved by a Level 3 diesel emissions control strategy for a similarly sized engine as defined by ARB regulations. A copy of each unit's certified tier specification, best available control technology documentation, and ARB or SCAQMD operating permit will be provided at the time of mobilization of each applicable unit of equipment.

3.2.5 Significant Unavoidable Adverse Impacts

There would be no significant unavoidable adverse impacts related to air quality.

3.2.6 Cumulative Impacts

Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time. The study area for cumulative effects on localized air quality is the area within 0.5 mile of the Project Site, and the study area for regional air pollutants is the Basin. The Project vicinity experiences exceedances of state and federal ambient air quality standards as a consequence of past and present projects and is subject to continued nonattainment status by reasonably foreseeable future projects.

Construction of the projects identified in the related projects list in Chapter 1, Introduction (see Table 1-1 of this EIR) could overlap with the construction of the Proposed Project. In this case, emissions would occur concurrently with those resulting from construction of the Proposed Project. Given that each of the projects will be required to mitigate its impacts and comply with Rule 403, impacts would not be cumulatively considerable and would not conflict with or obstruct implementation of SCAQMD's AQMP.

Operation of the Proposed Project could coincide with construction or operation of the projects identified in Chapter 1. With the exception of the Via Dolce Park and the Marina Beach General Improvements projects, all related projects are infrastructure projects that would not generate vehicle trips. The Via Dolce Park and the Marina Beach General Improvements projects are not expected to result in substantial trip generation; the Via Dolce Park would be small and generally used by local residents within walking distance of the park and the Marina Beach project would represent marginal improvements that would attract a minimal number of new trips to the Project area. Given the importance of vehicle emissions in overall emissions of projects, the Proposed Project in combination with related projects are not expected to result in cumulatively considerable increase in pollutant emissions and would not conflict with or obstruct implementation of SCAQMD's AQMP

SCAQMD has prepared, and periodically updates, the Basin's regional AQMP that sets forth a comprehensive and integrated program that will lead the Basin into compliance with the federal and state air quality standards. The Proposed Project would be consistent with the AQMP, which is intended to bring the Basin into attainment for all criteria pollutants.[2] Furthermore, construction-period emissions would be below SCAQMD regional and localized thresholds during construction

[2] CEQA Guidelines Section 15064(h)(3) states "A lead agency may determine that a project's incremental contribution to a cumulative effect is not cumulatively considerable if the project will comply with the requirements in a previously approved plan or mitigation program (including, but not limited to, water quality control plan, air quality attainment or maintenance plan, integrated waste management plan, habitat conservation plan, natural community conservation plan, plans or regulations for the reduction of greenhouse gas emissions) that provides specific requirements that will avoid or substantially lessen the cumulative problem within the geographic area in which the project is located. Such plans or programs must be specified in law or adopted by the public agency with jurisdiction over the affected resources through a public review process to implement, interpret, or make specific the law enforced or administered by the public agency. When relying on a plan, regulation or program, the lead agency should explain how implementing the particular requirements in the plan, regulation or program ensure that the project's incremental contribution to the cumulative effect is not cumulatively considerable. If there is substantial evidence that the possible effects of a particular project are still cumulatively considerable notwithstanding that the project complies with the specified plan or mitigation program addressing the cumulative problem, an EIR must be prepared for the project."

with the implementation of **Mitigation Measure AQ-1** (see Table 3.2-6 through Table 3.2-8) while operational emissions would be below SCAQMD regional and localized operational thresholds (see Table 3.2-9 and Table 3.2-10). The Proposed Project would comply with SCAQMD rules and regulations, including Rule 403 (Fugitive Dust Control) and Rule 1108 (Cutback Asphalt), during construction as well as all other adopted AQMP emissions control measures to minimize emissions and impacts on nearby sensitive receptors.

Per SCAQMD rules and mandates, as well as the CEQA requirement that significant impacts be mitigated to the extent feasible, these same requirements (i.e., Rule 403 compliance, the implementation of all feasible mitigation measures, and compliance with adopted AQMP emissions control measures) would also be imposed on all projects Basin-wide, including all nearby projects. For the reasons identified above (Project consistency with the AQMP, less-than-significant Project emissions, compliance with SCAQMD Rules, and the CEQA requirement that related projects mitigate impacts), Project emissions would not be cumulatively considerable during short-term construction or long-term operations.

3.3 Biological Resources

This section describes the affected environment and regulatory setting for the biological resources and jurisdictional areas of the Project Site and associated study area (see below). It also describes the potential impacts that would result from implementation of the Venice Auxiliary Pumping Plant (VAPP or Proposed Project) on these resources and provides mitigation measures, where necessary, to reduce or avoid such impacts. The environmental setting information and analysis in this section is summarized from the *Biological Resources and Habitat Assessment* and *Jurisdictional Delineation Report* (January 2016). These technical reports are hereby incorporated by reference and included as Appendices C and D, respectively of this EIR.

Within this section, the term "study area" refers to the Project Site plus an additional 500-foot buffer area surrounding the Project Site (see Figures 1-3 in Appendix C of this EIR). Special-status species referred to in this section include those plants and wildlife species listed as threatened or endangered under federal or state endangered species acts (California Department of Fish and Wildlife [CDFW] 2015a), plant species designated by the California Native Plant Society (CNPS) with a California Rare Plant Rank (CRPR) or other plants of local concern (CNPS 2015), and wildlife that is designated as a California Species of Special Concern, as defined by CDFW (CDFW 2015a).

The biological resources and jurisdictional delineation were conducted to provide recommendations for design and construction of the VAPP at the Project Site. Thus, the recommendations presented in these reports will be incorporated into project design and construction plans and specifications, and address biological resources and jurisdictional issues, including special-status plants and wildlife, threatened and endangered plants and wildlife, sensitive plant communities, essential fish habitat, non-listed special-status animals, nesting birds, raptor foraging, wildlife corridors, environmentally sensitive habitat areas, and jurisdictional areas, including waters of the United States and California and wetlands. As noted in the analysis below, with the implementation of mitigation measures, direct and indirect impacts associated with biological resources and to jurisdictional areas during construction or operation would be less than significant.

3.3.1 Regulatory Setting

A review of the various federal, state, regional, and local government regulatory requirements was conducted to identify regulations that provide protection of biological resources and wetlands. This section summarizes the various regulatory requirements that are relevant to the Proposed Project.

3.3.1.1 Federal Laws

Endangered Species Act of 1973 (16 U.S.C. Sections 1531 to 1543)

The Endangered Species Act of *1973* (ESA) and subsequent amendments provide guidance for the conservation of federally listed species and the habitats upon which they depend.

Prohibited Acts (ESA Section 9)

ESA Section 9 prohibits the "take" of any fish or wildlife species listed under ESA as threatened or endangered, unless otherwise authorized by federal regulations. "Take" means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct. There are two processes, ESA Section 7 and ESA Section 10, whereby take can be allowed for activities when they are incidental to an otherwise legal activity.

Interagency Consultation and Biological Assessments (ESA Section 7)

ESA Section 7 provides a means for authorizing take of threatened or endangered species by federal agencies and applies to actions that are conducted, permitted, or funded by a federal agency. It requires federal agencies to consult with the U.S. Fish and Wildlife Service (USFWS) or National Marine Fisheries Service (NMFS), as appropriate, to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of threatened or endangered species or result in the destruction or adverse modification of critical habitat for these species. If a proposed project "may affect" a listed species or destroy or modify critical habitat, the lead agency is required to prepare a biological assessment evaluating the nature and severity of the potential effect.

Habitat Conservation Plans (ESA Section 10)

ESA Section 10 requires obtaining an Incidental Take Permit from the USFWS, for non-federal activities that might incidentally harm (or "take") endangered or threatened wildlife. In order to obtain a permit, a Habitat Conservation Plan must be developed to offset any harmful effects the proposed activity might have on the species.

Section 404 of the *Clean Water Act of 1977* (33 U.S.C. Sections 1251 to 1376)

The Clean Water Act of 1977 (CWA) serves as the primary federal law protecting the quality of the nation's surface waters, including wetlands. Under Section 404, the U.S. Army Corps of Engineers (USACE) and the U.S. Environmental Protection Agency (EPA) regulate the discharge of dredged and fill materials into the waters of the United States. These waters are primarily defined as navigable waterways or water features (including wetlands) that have a significant nexus to navigable waters. Project sponsors must obtain authorization from USACE for all discharges of dredged or fill materials into waters of the United States before proceeding with a proposed activity. Individual Section 404 permits may only be issued for a least environmentally damaging practicable alternative. Compliance with CWA Section 404 requires compliance with several other environmental laws and regulations. The USACE cannot issue an individual permit or verify the use of a general permit until the requirements of National Environmental Policy Act of 1969 (NEPA), ESA, the Coastal Zone Management Act (CZMA) and the National Historic Preservation Act (NHPA) have been met. Additionally, no permit can be issued or verified until a water quality certification, or waiver of certification, has been issued pursuant to CWA Section 401.

Protection of Wetlands (Executive Order 11990)

Executive Order 11990 (*Federal Register*, Volume 42, Number 26 [May 24, 1977], p. 3) aims to avoid direct or indirect support of new construction in wetlands when a practicable alternative is available. If wetland effects cannot be avoided, all practicable measures to minimize harm must be included.

Coastal Zone Management Act (16 U.S.C. Section 1451 et seq.)

The CZMA encourages states to preserve, protect, develop, and where possible, restore or enhance valuable natural coastal resources such as wetlands, floodplains, estuaries, beaches, dunes, barrier islands, and coral reefs, as well as the fish and wildlife using those habitats. Participation in the CZMA is voluntary, however, it makes federal financial assistance available to any coastal state, tribe, or territory that is willing to develop and implement a comprehensive coastal management program.

Fish and Wildlife Coordination Act (16 U.S.C. Sections 661 to 667e et seq.)

The Fish and Wildlife Coordination Act applies to any federal project where any body of water is impounded, diverted, deepened, or otherwise modified. Project proponents are required to consult with USFWS and the appropriate state wildlife agency.

Migratory Bird Treaty Act (MBTA) (16 U.S.C. Sections 703 to 712)

The Migratory Bird Treaty Act (MBTA) protects migratory birds and their parts (including eggs, nests, and feathers). The MBTA prohibits killing, possessing, or trading in migratory birds, except in accordance with regulations prescribed by the Secretary of the Interior. Projects that are likely to result in the taking of birds protected under the MBTA will require the issuance of take permits from the USFWS. Activities that would require such a permit would include, but not be limited to, removal of nests, eggs, and feathers.

Protection of Migratory Bird Populations (Executive Order 13186)

Executive Order 13186 (*Federal Register*, Volume 66, Number 11 [January 17, 2001], p. 4) directs each federal agency taking actions that have or may have adverse impact on migratory bird populations to work with USFWS to develop a memorandum of understanding that will promote the conservation of migratory bird populations. This includes avoiding and minimizing adverse impacts on migratory bird resources when conducting agency actions, restoring and enhancing migratory bird habitats, and preventing or abating the pollution or detrimental alteration of the environment for the benefit of migratory birds.

Invasive Species (Executive Order 13112)

Executive Order 13112 (*Federal Register*, Volume 64, Number 25 [February 8, 1999], p. 3) requires federal agencies to work cooperatively to prevent and control the introduction and spread of invasive plants and animals.

3.3.1.2 State Laws

California Coastal Act (Public Resource Code Division 20, Section 30000 et seq.)

The California Coastal Act is the state's Coastal Zone Management Program, as referenced under the CZMA, above. The California Coastal Act defines the "coastal zone" of California as extending generally 1,000 feet (305 meters) inland from the coast and 3 miles (5 kilometers) seaward. In certain areas, the inland boundary can extend up to 5 miles (8 kilometers). The California Coastal Act requires a Coastal Development Permit (CDP) from either the Coastal Commission or the City Engineer, as a local permit issuing agency. For this project, the work within the Grand Canal will require a state CDP, while work outside of the canal will require both state and local CDPs.

Porter-Cologne Water Quality Control Act (California Water Code Division 7)

The Porter-Cologne Water Quality Control Act (Porter-Cologne) established nine Regional Water Quality Control Boards (RWQCBs). These boards oversee water quality on a day-to-day basis at the local and/or regional level, and prepare and update water quality control plans. The RWQCBs also issue Section 401 water quality certifications under the federal Clean Water Act. Porter-Cologne also grants ultimate authority to the State Water Resources Control Board (SWRCB) over state water rights and water quality policy.

California Fish and Game Code

California Endangered Species Act (Sections 2050 to 2085)

The California Endangered Species Act (CESA) establishes the policy of the state to conserve, protect, restore, and enhance threatened or endangered species and their habitats, by protecting "…all native species of fishes, amphibians, reptiles, birds, mammals, invertebrates, and plants, and their habitats, threatened with extinction and those experiencing a significant decline which, if not halted, would lead to a threatened or endangered designation." It mandates that state agencies do not approve a project that would jeopardize the continued existence of these species if reasonable and prudent alternatives are available that would avoid a jeopardy finding. There are no state agency consultation procedures under CESA. For projects that would affect species that are federally and state-listed, compliance with the federal ESA satisfies CESA if CDFW determines that the federal incidental take authorization is consistent with CESA under Section 2080.1. For projects that would result in take of a species that is state-listed only, the project sponsor must apply for a take permit in accordance with Section 2081(b).

California Native Plant Protection Act (Sections 1900 to 1913)

The California Native Plant Protection Act requires all state agencies to utilize their authority to carry out programs to conserve endangered and rare native plants. It prohibits importation, take, and sale of such plants. The CESA defers to the California Native Plant Protection Act of 1977 (California Fish and Game Code Sections 1900–1913), which ensures that state-listed plant species are protected.

Bird Nesting Protections (Sections 3503 and 3503.5)

Bird Nesting Protections state that it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, except as otherwise provided by this code or any regulation made pursuant thereto. To avoid violation of the take provisions, it is generally required that project-related disturbance at active nesting territories be reduced or eliminated during the nesting cycle.

Fully Protected Species (Sections 3511, 4700, 5050, 5515)

Four sections of the *California Fish and Game Code* list 37 fully protected species (California Fish and Game Code Sections 3511, 4700, 5050, and 5515) and prohibit take or possession "at any time" of the species listed, with few exceptions, and state that "…no provision of this code or any other law shall be construed to authorize the issuance of permits or licenses to 'take' the species," …and that no previously issued permits or licenses for take of the species shall have any force or effect…" for authorizing take or possession.

3.3.2 Environmental Setting

This section describes the environmental setting or conditions related to biological resources and jurisdictional areas within the project study area. This information is intended to assist in the evaluation and conclusions of the impact analysis provided below and in the formation of required mitigation measures.

3.3.2.1 Vegetation/Land Use Types

The study area is composed of ornamental vegetation associated with developed and/or disturbed lots surrounding the Grand Canal and Ballona Lagoon, both of which contain native plant communities with varying composition of non-native species. Table 3.3-1 summarizes the vegetation communities within the study area. The location of each vegetation community within the study area can be found in Figure 3 in Appendix C of this EIR.

Table 3.3-1. Vegetation Communities/Land Use/Land Conditions within the Study Area

Vegetation Community/Land Use/Land Condition	Acres
Developed	24.60
Disturbed/Ruderal	0.18
Open Water	3.13
Southern Coastal Salt Marsh	0.86
Coastal Brackish Marsh	0.16
Southern Foredunes	0.43
Southern Coastal Bluff Scrub	0.35
Total	**29.74**
Source: ICF, 2015.	

Developed and Disturbed/Ruderal

Developed lands within the study are associated with the residential structures and surface roads and include ornamental vegetation typically associated with the developed areas such as Mexican fan palm (*Washingtonis robusta*), acacia (*Acacia* sp.), eucalyptus (*Eucalyptus* sp.), Peruvian pepper tree (*Schinus molle*), iceplant (*Carpobrotus* sp.), and myoporum (*Myoporum* sp.). The disturbed/ruderal vegetation type consists of both native and non-native annual and perennial plant species such as iceplant, garland chrysanthemum (*Glebionis coronaria*), telegraphweed (*Heterotheca grandifolia*), cheeseweed (*Malva parviflora*), Bermuda grass (*Cynodon dactylon*), and Australian saltbush (*Atriplex semibaccata*).

Open Water

Open Water consists of the tidal influenced Grand Canal and Ballona Lagoon. Grand Canal opens to Marina Del Rey Marina approximately 4,000 feet to the south through a flood gate system under Via Marina road. Mudflats occur within the tidally influenced portions of the Biological Survey Area (BSA) and exposed areas of mudflats fluctuate with tide action. A small strip of exposed mudflat occurs within the project footprint during low tides within this habitat type.

Southern Coastal Salt Marsh

This vegetation type was identified within the tidal zone of the Grand Canal and Ballona Lagoon and is dominated by native wetland species such as pickleweed (*Sarcocornia pacifica*), batis (*Batis maritima*), wooly seablight (*Suaeda taxifolia*), spearscale (*Atriplex prostrata*), and fleshy jaumea (*Jaumea carnosa*). Wooly seablight is a CNPS CRPR List 4.2 species (plants of limited distribution). Within the wetland-upland interface, species such as salt grass (*Distichilis spicata*), five-hooked bassia (*Bassia hyssopifolia*), beach bur (*Ambrosia chamissonis*), and alkali heath (*Frankenia salina*) are present.

Coastal Brackish Marsh

This vegetation type was identified immediately above the tidal zone of the Grand Canal and Ballona Lagoon. This area is dominated by species such as alkali heath, salt grass, five-hooked bassia, wooly seablight, beach bur, alkali heliotrope (*Heliotropium curassavicum*), and deerweed (*Acmispon glaber*). The lower portion of this area transitions to wetland species such as pickleweed, batis, and fleshy jaumea.

Southern Foredunes

This vegetation type was identified on the western side of Ballona Lagoon within the southwestern portion of the study area. This area is dominated by upland coastal dune and maritime sage scrub species. Dominant species observed on the western side of the lagoon include beach bur, deerweed, bluff buckwheat (*Eriogonum parviflora*), red sand verbena (*Abronia maritima*[1]), beach evening primrose (*Camissonia cheiranthifolia*), southwestern spiny rush (*Juncus acutus* ssp. *leopoldii*[2]), telegraphweed (*Heterotheca grandifolia*), and Watson's saltbush (*Atriplex watsonii*).

Southern Coastal Bluff Scrub

This vegetation type was identified on the eastern side of Ballona Lagoon. Dominant species observed in this area include southwestern spiny rush, California encelia (*Encelia californica*), California sagebrush (*Artemisia californica*), prickly-pear cactus (*Opuntia littoralis*), and lemonade berry (*Rhus integrifolia*).

3.3.2.2 Plants

Most plant species that were observed within the study area are considered common within the study area vicinity and include a mix of native and non-native species. However, three special-status species were determined to be present within the study area: wooly seablite, southwestern spiny rush, and red sand verbena, each of which is CNPS CRPR List 4.2 species. In addition, suitable habitat for other special-status plant species is present within the study area and is discussed in more detail in Section 3.3.2.5, Special-Status Species. Appendix C of this EIR provides a list of all plant species observed on the Project Site during the habitat assessment.

Common native plant species observed during the habitat assessment included the following species: lemonade berry (*Rhus integrifolia*), California sagebrush(*Artemisia californica*), California encelia (*Encelia californica*), telegraphweed (*Heterotheca grandifolia*), alkali heath (*Frankenia*

[1] *Abronia maritima* is designated as a CNPS CRPR 4.2 species.
[2] *Juncus acutus* is designated as a CNPS CRPR 4.2 species.

salina), alkali heliotrope(*Heliotropium curassavicum*), prickly-pear cactus (*Opuntia littoralis*), saltwort, deerweed (*Acmispon glaber*), salt grass (*Distichilis spicata*), gut weed (*Ulva intestinalis*), sea lettuce (*Ulva lactuca*), western ragweed (*Ambrosia psilostachya*), ragweed (*Ambrosia* sp.), coastal goldenbush (*Isocoma menziesii*), beachwort (*Batis maritima*), mouse-ear chickweed (*Cerastium* sp.), Parish's pickleweed (*Arthrocnemum subterminale*), big saltbush (*Atriplex lentiformis*), saltbush (*Atriplex* sp.), Pacific pickleweed (*Salicornia pacifica*), pickleweed (*Salicornia* sp.), salt dodder (*Cuscuta salina*), vetch (*Vicia* sp.), suncup (*Camissonia* sp.), seacliff buckwheat (*Eriogonum parvifolium*), nightshade (*Solanum* sp.), and brittlegrass (*Setaria* sp.).

Common non-native species observed during the habitat assessment included: Mexican fan palm (*Washingtonis robusta*), acacia (*Acacia* sp.), eucalyptus (*Eucalyptus* sp.), Australian saltbush(*Atriplex semibaccata*), Bermuda grass (*Cynodon dactylon*), flax-leaved horseweed (*Erigeron bonariensis*), five-hooked bassia, cheeseweed, baby sun-rose (*Aptenia cordifolia*), fat-hen (*Atriplex prostrata*), hottentot fig (*Carpobrotus* sp.), Lamb's quarters (*Chenopodium album*), whitestem filaree (*Erodium moschatum*),spotted spurge (*Euphorbia maculate*), crown daisy (*Glebionis coronaria*), grass poly (*Lythrum hyssopifolia*), Ngaio tree (*Myoporum laetum*), Brazilian pepper tree (*Schinus terebinthifolius*), sowthistle (*Sonchus* sp.), and puncturevine (*Tribulus terrestris*).

3.3.2.3 Wildlife

Wildlife species observed within the study area are considered common to the general project vicinity. The majority of species recorded were birds such as mallard (*Anas platyrhynchos*), mourning dove (*Zenaida macroura*), Anna's hummingbird (*Calypte anna*), white-throated swift (*Aeronautes saxatalis*), barn swallow (*Hirundo rustica*), cliff swallow (*Petrochelidon pyrrhonota*), northern rough-winged swallow (*Stelgidopteryx serripennis*), black phoebe (*Sayornis nigricans*), American crow (*Corvus brachyrhynchos*), common raven (*Corvus corax*), European starling (*Sturnus vulgaris*), house finch (*Carpodacus mexicanus*), double-crested cormorant (*Phalacrocorax auritus*), great blue heron (*Ardea herodias*), great egret (*Ardea alba*), osprey (*Pandion haliaetus*), American coot (*Fulica americana*), black-bellied plover (*Pluvialis squatarola*), willet (*Tringa semipalmata*), whimbrel (*Numenius phaeopus*), marbled godwit (*Limosa fedoa*), and belted kingfisher (*Ceryle alcyon*). Marine invertebrates observed included buckshot barnacles (*Chthalamus* spp.), blue mussel (*Mytilus edulis*), California horn snail (*Cerithidea californica*), California mussel (*Mytilus californianus*), checkered limpet (*Lottia strigatella*), Gould's bubble snail (*Bulla gouldiana*), and Pacific oyster (*Ostrea lurida*). Marine vertebrates observed included California corbina (*Menticirrhus undulates*) and topsmelt (*Atherinops affinis*). Additional marine invertebrates observed within the Grand Canal include commonly occurring bivalves, mollusks, and crustaceans (LADPW 2005).

Appendix C of this EIR provides a list of all wildlife species observed on the Project Site during the habitat assessment.

Suitable habitat for several special-status wildlife species is present within the study area and is discussed in more detail in Section 3.3.2.5, Special-Status Species.

3.3.2.4 Federal and State Jurisdictional Aquatic Resources

Within the jurisdictional delineation study area (see Appendix D of this EIR), two named features that could be subject to the jurisdiction of the USACE, RWQCB/EPA, and the California Coastal Commission (CCC) were delineated: Ballona Lagoon and Grand Canal. These two features are treated as one for the purpose of this document. USACE and RWQCB potential jurisdictional areas within the study area total approximately 0.929 acre of Section 404 non-wetland waters of the

United States/Section 401 non-wetland waters of the state and 0.075 acre of Section 404 wetland waters of the United States and Section 401 wetland waters of the state. Additionally, 0.793 acre of potential USACE Section 10 waters of the United States was mapped in the study area. Potential CCC jurisdiction within the study area totaled approximately 0.929 acre of one-parameter wetlands.

3.3.2.5 Special-Status Species

Special-status species are plants and animals that are legally protected under the CESA, the federal ESA, or other regulations, as well as species considered sufficiently rare by the scientific community to qualify for such listing.

Special-Status Plants and Sensitive Vegetation Communities

A total of 47 special-status plant species were evaluated to have a potential to occur within the geographical vicinity of the project area. Thirteen are identified as federally and/or state threatened and endangered plant species, but are absent based on the absence of suitable habitat within the study area, the species being extirpated from the region, and/or recent negative floristic surveys for the Venice Tide Gate Project (LADPW 2005) and at the adjacent Ballona Wetlands. Thirty-four federal and/or state non-listed special-status plants were reviewed to have a potential to occur within the geographical vicinity of the project area. Three were determined to be present and include woolly seablite, southwestern spiny rush, and red sand verbena; identified as CNPS CRPR 4.2 species.

Three sensitive vegetation communities as defined by CDFW occur within the project vicinity: Southern Coastal Bluff Scrub, Southern Coastal Salt Marsh, and Southern Dune Scrub. Each of these communities occurs within the study area; however, only Southern Coastal Salt Marsh occurs within the disturbance footprint (see Figure 3.3-1).

Special-Status Wildlife

A total of 37 special-status wildlife species were evaluated to have potential to occur within the geographical vicinity of the project area. Twenty two are identified as federally and/or state listed wildlife species and three were identified to have a low potential to occur or low to high potential to breed or forage and include the federally endangered El Segundo blue butterfly, state endangered Belding's savannah sparrow, federally endangered, state endangered, and state fully protected light-footed clapper rail, and federally and state endangered California least tern. There are 15 non-listed special-status species reviewed to have some potential to occur within the geographical vicinity of the project area (CDFW 2015a). None of these species are judged to have a potential for occurrence based on current habitat conditions within the study area.

No USFWS-designated critical habitat for federally threatened and/or endangered wildlife species is present and there is no essential fish habitat is known occur in the study area.

3.3.2.6 Nesting Birds

All developed and undeveloped portions of the study area contain suitable nesting habitat for a variety of avian species including, but not limited to, those species observed during the habitat assessment (see Appendix C of this EIR)

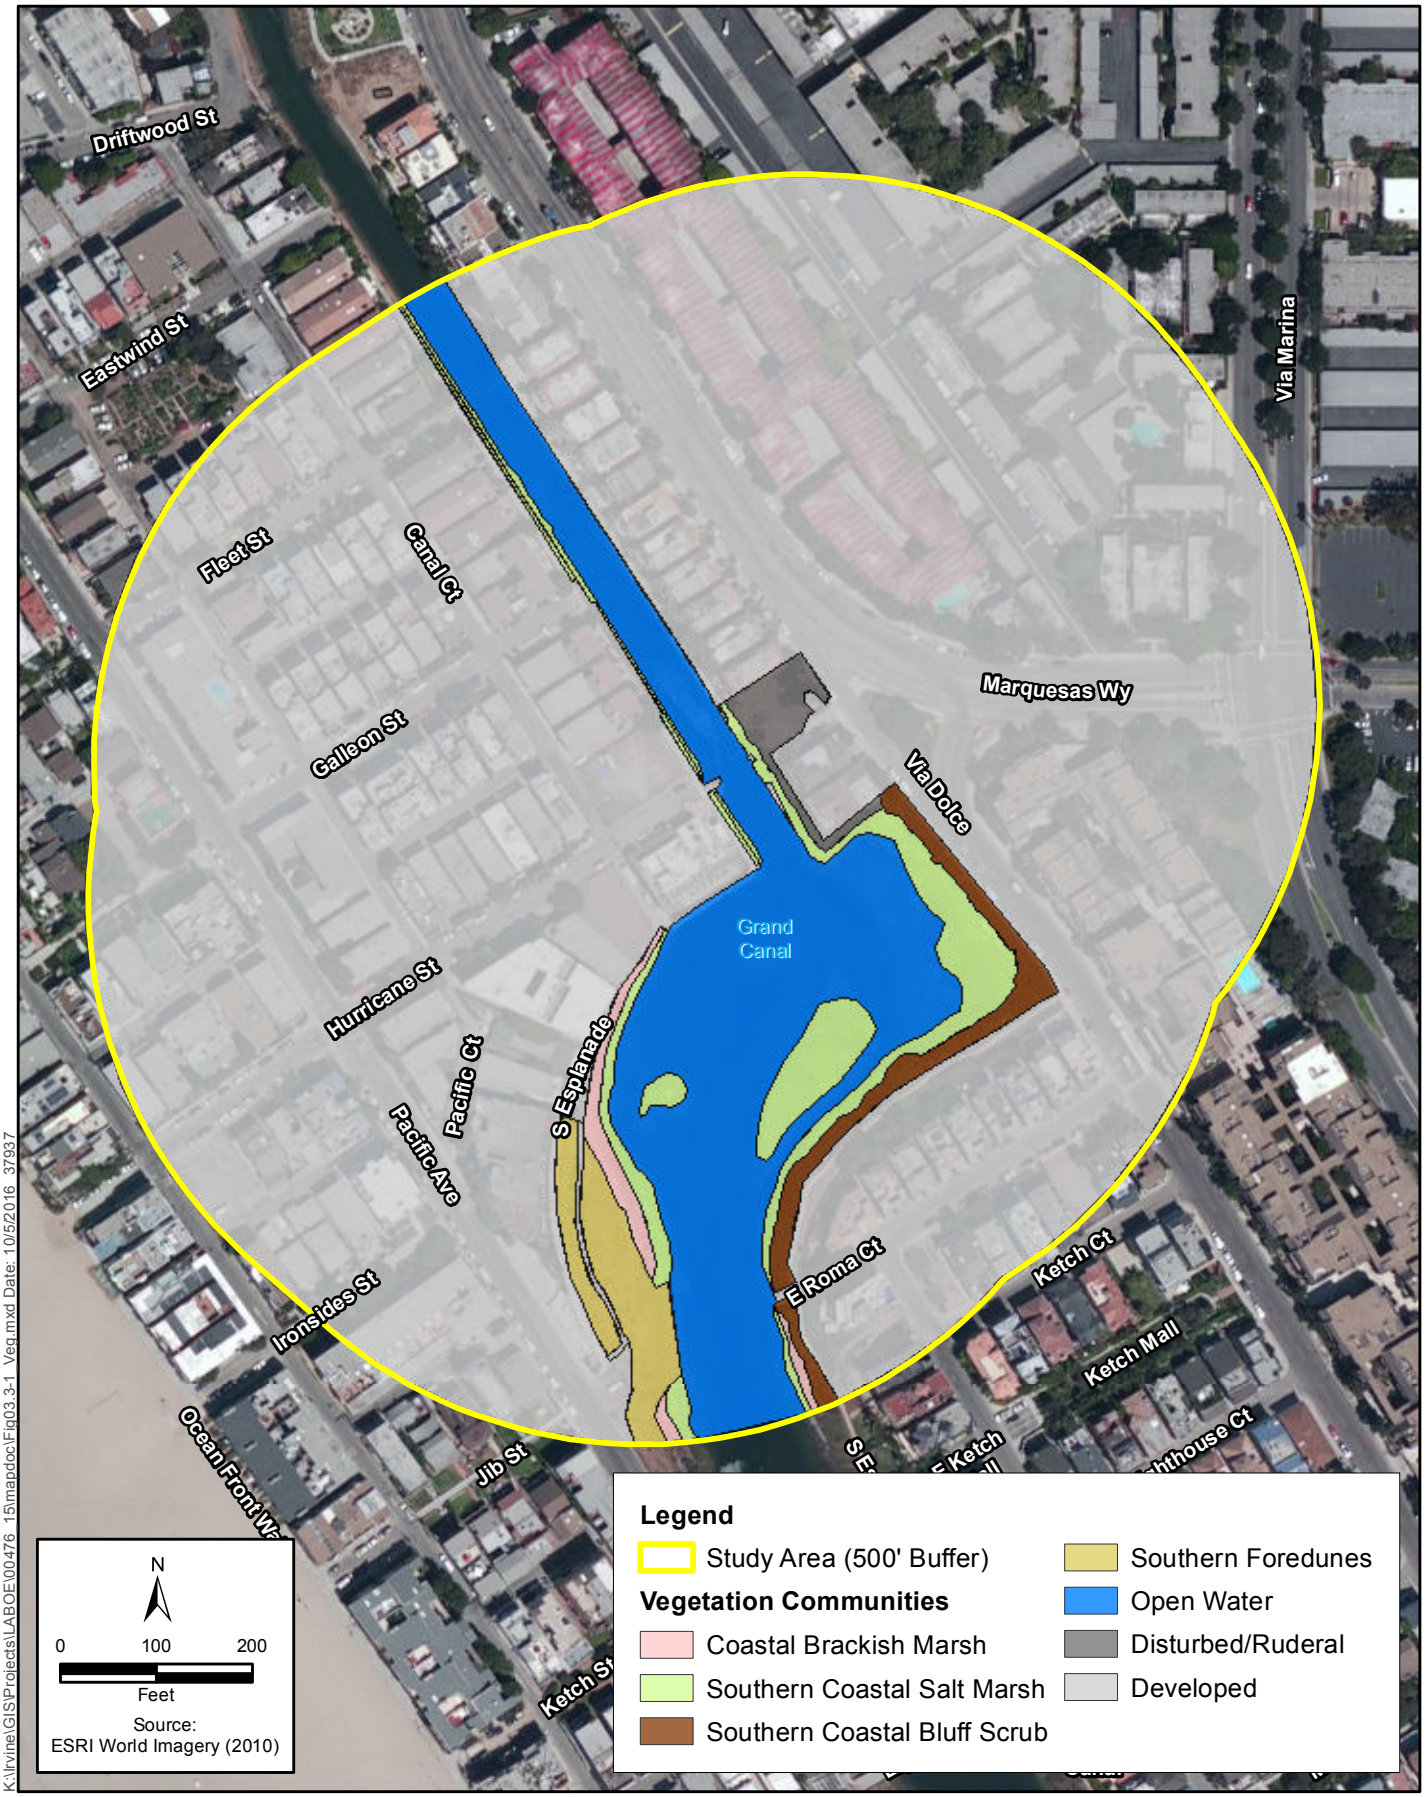

Figure 3.3-1
Vegetation Communities
Venice Auxiliary Pumping Plant Project

3.3.2.7 Raptor Foraging

The study area was evaluated for its potential to support raptor foraging activities. Due to the lack of expansive open areas, the study area would generally not be considered high quality raptor foraging habitat, although it provides foraging opportunities for some raptors that occupy developed areas.

3.3.2.8 Wildlife Corridors

No traditional wildlife corridors linking two regional habitats are identified within the study area as a result of the surrounding urban development and lack of habitat connectivity and upstream hydrological connectivity to any other aquatic resource. However, Grand Canal and Ballona Lagoon provide refuge and foraging habitat for aquatic species and these canals function in part as a partial wildlife corridor despite no upslope connectivity. Therefore, Grand Canal and Ballona Lagoon are treated here as a type of wildlife corridor.

3.3.2.9 Environmentally Sensitive Habitat Areas

The Grand Canal and Ballona Lagoon are classified as an ESHA by the CCC and County of Los Angeles because of their plant and wildlife resources within the local ecosystem. Portions of the Ballona Lagoon have been restored and have increased the functions and values of biological resources within the portion of the ESHA where the project is proposed (Hamilton 2010).

3.3.3 Environmental Impact Analysis

3.3.3.1 Methodology

Potential significant impacts associated with the Proposed Project were identified from the *Biological Resources and Habitat Assessment* and *Jurisdictional Delineation Report* (January 2016). These reports presented findings, conclusions, and recommendations concerning development of the Project Site that were based on an analysis of the existing biological resources and jurisdictional areas contained within the study area and which could be affected by the Proposed Project during construction and operation.

Direct impacts occur when sensitive biological resources are altered through project implementation, such as through vegetation removal, habitat modifications, and injury or death of wildlife species. Indirect impacts may occur from elevated levels of noise or lighting, changes in surface water hydrology, or increased erosion or sedimentation. These types of indirect impacts can affect vegetation communities or their potential use by sensitive wildlife species.

The discussion below identifies potential project impacts and the measures that would be required to mitigate impacts that are found to be potentially significant.

3.3.3.2 Screening Analysis

As noted in Section Chapter 1., Introduction (of this Draft EIR), the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.3.3.3 Thresholds of Significance

The criteria used to determine the significance of an impact on biological resources are based on *L.A. CEQA Thresholds Guide*. A project would normally have a significant impact on biological resources if it could result in:

- **BIO-1.** The loss of individuals, or the reduction of existing habitat, of a state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat;
- **BIO-2.** The loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community;
- **BIO-3.** Interference with habitat such that normal species behaviors are disturbed (e.g., from the introduction of noise, light) to a degree that may diminish the chances for long-term survival of a sensitive species;
- **BIO-4.** The alteration of an existing wetland habitat; or
- **BIO-5.** Interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species.

3.3.3.4 Construction Impacts

The analysis below describes the temporary and permanent short-term and long-term direct and indirect impacts on vegetation communities and other sensitive biological resources anticipated as a result of the Proposed Project during construction.

BIO-1. Would the project result in the loss of individuals, or the reduction of existing habitat, of a state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat?

The analysis below address potential impacts that could occur to biological resources and essential fish habitat during construction related to the loss or reduction of sensitive species and associated habitats as well as critical habitat important to their life cycle.

Special-Status Plants

Woolly seablite, southwestern spiny rush, and red sand verbena, each of which is classified as a CNPS CRPR List 4.2 species (plants of limited distribution) were observed in the study area, but are currently absent within the disturbance footprint, and as a result, no impacts on individuals or populations are anticipated. *Suaeda taxifolia,* a CRPR List 4.2 species, is in a location, which may be affected by construction along the canal banks, as shown in Figure 3 (see Appendix C of this EIR). If these species were to inhabit the disturbance footprint during construction, then impacts would be potentially significant. **Mitigation Measure MM-BIO-1** (see Section 3.3-4), which requires completion of special-status plant surveys prior to initiating construction, will ensure the project will not have a substantial adverse effect, either directly or through habitat modifications, or result in the loss of individuals, or the reduction of existing habitat, of a local, state or federally listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat. Therefore, impacts on special-status plants would be **less than significant with mitigation incorporated.**

Special-Status Wildlife

Four special-status wildlife species could be affected during construction of the Proposed Project, as discussed below.

El Segundo Blue Butterfly

The likelihood of occurrence of El Segundo blue butterfly within the project limits is low, based on the lack of lack of suitable habitat and host plant sea cliff buckwheat (*Eriogonum parviflora*). It is possible that stray individuals could temporarily occupy the adjacent restoration area along the western portion of Ballona Lagoon outside of the project footprint; however, no temporary direct or indirect impacts would occur given the disturbance footprint is approximately 390 feet northeast from the closest habitat containing the host plant. As such, there is a low probability of direct or indirect temporary impacts on this species during construction. In the event this species is present in the host plant during construction, impacts would be potentially significant. Although the host plant sea cliff buckwheat (*Eriogonum parvifolium*) is not a sensitive species, **Mitigation Measure MM-BIO-1**, conducting special-status plant surveys prior to initiating construction, would ensure that no host plants have established within the disturbance footprint prior to construction.

No permanent direct or indirect impacts on El Segundo blue butterfly are anticipated during construction based on the lack of suitable habitat and host plant sea cliff buckwheat (*Eriogonum parviflora*), within the project footprint.

Mitigation Measure MM-BIO-2, monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, would ensure that no temporary impacts would occur to El Segundo blue butterfly. Therefore, impacts on special-status wildlife would be **less than significant with mitigation incorporated.**

Belding's Savannah Sparrow

Belding's savannah sparrow has a moderate potential to forage within the study area due to the nearby population at Ballona Wetlands, although the species has not been observed within Ballona Lagoon or Grand Canal and no records of occurrence are known within the study area (CNDDB 2015). As such, direct or indirect temporary impacts on this species could potentially occur during construction.

Implementation of **Mitigation Measure MM-BIO-2**, which requires monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, would reduce this impact to less than significant levels. Therefore, impacts on special-status wildlife would be **less than significant with mitigation incorporated.**

Light-Footed Clapper Rail

Light-footed clapper rail has a low potential to forage within the study area due to the nearby population at Ballona Wetlands; however, the study area is relatively isolated, lacks quality habitat, and this species has not been observed within Ballona Lagoon or the Grand Canal and no records of occurrence within the study area are known (CNDDB 2015). Nevertheless, direct or indirect temporary impacts on this species could potentially occur during construction.

Mitigation Measure MM-BIO-2, monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, would ensure that no temporary impacts would occur to light-footed clapper rail.

No permanent direct or indirect impacts on light-footed clapper rail would occur as a result of the project during construction due to restoration of the disturbance footprint following construction.

Mitigation Measure MM-BIO-3, restoration of the disturbance footprint following construction, would ensure that permanent direct impacts would be less than significant.

Impacts on special-status wildlife would be **less than significant with mitigation incorporated.**

California Least Tern

California least tern has a less than reasonable potential to breed within the study area due to lack of suitable habitat; nearby suitable and protected breeding grounds are located approximately 0.6 miles from the study area. This species is well known to forage within the study area, however.

As such, construction has the potential to adversely affect this species temporarily. Installation of the cofferdam could cause an increase in turbidity that could have temporary indirect impacts on California least tern foraging either by reducing local prey availability and/or by reducing visibility of prey in the vicinity. Any construction activities conducted during the California least tern nesting season when terns are present could also cause temporary impacts in the form of noise and increased human disturbance that may attract tern predators such as the American crow and common raven. These predators could result in nest predation within the tern colony. Impacts on this species could be potentially significant.

Mitigation Measures MM-BIO-2, monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, MM-BIO-4 properly dispose of all garbage, MM-BIO-5 monitor water quality, and MM-BIO-6 conduct a nesting bird survey during the breeding season, would ensure that impacts on foraging California least tern would be **less than significant**.

No permanent direct or indirect impacts on California least tern would occur as a result of the project during construction due to restoration of the disturbance footprint following construction.

Mitigation Measure MM-BIO-3, restoration of the disturbance footprint following construction, would ensure that permanent direct impacts would be **less than significant**.

Nesting Birds

The study area and disturbance footprint support marginally suitable habitat for nesting birds. As such, direct and indirect temporary impacts on nesting species within the study area could potentially occur during construction. The areas to be affected during construction support potential nesting habitat for ground-nesting birds, such as black-necked stilt (*Himantopus mexicanus*) and killdeer (*Charadrius vociferous*), as well as habitat for a few species that commonly nest in structures and trees in developed areas. Impacts on nesting birds protected under the Migratory Bird Treaty Act and California Fish and Game Code Sections could be potentially significant if construction activity takes place during the bird breeding season.

Implementation of **Mitigation Measure MM-BIO-6**, which requires a nesting bird survey to be conducted during the nesting bird season and prior to any disturbance within the study area to document the presence or absence of nesting birds, would ensure that no temporary impacts would occur to nesting birds.

Following construction, the project disturbance footprint within Grand Canal would be restored to original conditions. In addition, **Mitigation Measures MM-BIO-2**, which requires monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, would be implemented. Implementation of **Mitigation Measures MM-BIO-4**, properly dispose of all garbage, MM-BIO-5, monitor water quality, and MM-BIO-6, conduct a nesting bird survey during the breeding season, would also ensure that permanent impacts on nesting birds would be **less than significant with mitigation incorporated** should the project occur during the nesting season.

Raptor Foraging

Raptors such as osprey, Cooper's hawk, and red-tailed hawk are generally not expected to nest within the study area due to the disturbed and developed nature of the project; however, limited foraging habitat does occur for some raptor species. Because the project impacts within natural habitats would be limited to a relatively small and defined portion of the Grand Canal and to a lesser extent Ballona Lagoon within the context of an urban environment and are temporary in nature, they are not considered significant. Implementation of **Mitigation Measures MM-BIO-2**, monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, MM-BIO-4 properly dispose of all garbage, MM-BIO-5 monitor water quality, and MM-BIO-6 conduct a nesting bird survey during the breeding season, would ensure that impacts on raptors would be **less than significant**.

Essential Fish Habitat

No designated Essential Fish Habitat is present within the study area; therefore**; no impacts** would occur during construction and no mitigation is required.

BIO-2. Would the project result in the loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community?

The analysis below addresses potential impacts that could occur on vegetation communities and ESHA during construction, resulting in the loss of individuals or the reduction of existing habitat, locally designated species, natural habitat, or plant community.

Vegetation Communities

Temporary and permanent direct impacts on vegetation communities resulting from construction activities are quantified in Table 3.3-2. These impacts are considered significant. Implementation of **Mitigation Measures, MM-BIO-2** monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, BIO-3 restoration of the disturbance footprint following construction, MM-BIO-7 construction limits will be identified using silt fencing, and

MM-BIO-9 restoration of mudflat, would reduce the potential that the Proposed Project would cause the loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community. Therefore, impacts on this sensitive vegetation community would be **less than significant with mitigation incorporated.**

Table 3.3-2. Temporary and Permanent Impacts on Vegetation Communities/Land Use/Land Conditions within the Study Area

Vegetation Community/Land Use/Land Condition	Temporary Impacts (acres)	Permanent Impacts (acres)
Developed	0.17	0.27
Disturbed/Ruderal	0.12	-
Open Water	0.06	
Southern Coastal Salt Marsh	0.02	-
Coastal Brackish Marsh	0.003*	-
Southern Foredunes	-	-
Southern Coastal Bluff	-	-
Total	**0.37**	**0.27**

*Temporary impacts are negligible and this community would be avoided during project construction. Mitigation Measures MM-BIO-2, BIO-3, and 7 would also be implemented.
Source: ICF, 2016.

Environmentally Sensitive Habitat Areas

The Grand Canal and Ballona Lagoon are classified as an ESHA by the CCC and County of Los Angeles because of their plant and wildlife resources within the local ecosystem. Direct and indirect temporary impacts on the ESHA as a result of project construction could be significant. Implementation of **Mitigation Measures MM-BIO-7**, construction limits will be identified using silt fencing, and MM-BIO-8, existing and potential values in ESHA shall be protected, enhanced, and restored as necessary to previous undisturbed conditions, would limit the potential that project construction would result in the loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community. No permanent impacts would occur as a result of the Proposed Project. Therefore, impacts on the ESHA would be **less than significant with mitigation incorporated.**

BIO-3. Would the project result in an interference with habitat such that normal species behaviors are disturbed (e.g., from the introduction of noise, light) to a degree that may diminish the chances for long-term survival of a sensitive species?

The Proposed Project includes temporary direct impacts on the Grand Canal, its banks, and adjacent undeveloped lots to be used as construction laydown areas (see Chapter 2, Figure 2-2, of this EIR). The Grand Canal would also receive increased light exposure from temporary construction lighting that will be installed to prevent incursion into the construction area. Temporary indirect impacts may occur during construction and include increased sedimentation as a result of installation and removal, minor alteration of surface water hydrology within the Grand Canal from the coffer dam, construction noise and lighting, as well as dust and other particulates that may become airborne

during construction. These impacts could be significant and could diminish the chances of long-term survival of a sensitive species. However, with implementation of **Mitigation Measures MM-BIO-1**, conducting special-status plant surveys prior to initiating construction, **MM-BIO-2**, monitoring of all vegetation removal and ground-disturbing activities for the duration of the project to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species, **MM-BIO-4**, properly dispose of all garbage, **MM-BIO-5**, monitor water quality, **MM-BIO-6**, conduct a nesting bird survey during the breeding season, and **MM-BIO-7**, construction limits will be identified using silt fencing, impacts would be reduced to **less than significant with mitigation incorporated** during construction**.**

BIO-4. Would the project result in the alteration of an existing wetland habitat?

The Proposed Project would occur within the jurisdiction of several agencies including, but not limited to, USACE, RWQCB, and CCC and would result in temporary direct and indirect impacts on aquatic resources, including an existing wetland habitat through the construction of the components within the Grand Canal (see Figure 3.3-2). These impacts would be significant. No permanent direct or indirect impacts would occur because all impacts would be below grade and the original grade would be restored to pre-construction conditions. Table 3.3-3 below quantifies temporary impacts on jurisdictional waters and wetlands regulated by each of the agencies. Applicable permits from resource agencies would be obtained during the permitting phase prior to construction and all permit conditions and avoidance and minimization measures would be implemented. **Mitigation Measures MM-BIO-3**, restoration of the disturbance footprint following construction, **MM-BIO-5** monitor water quality, and **MM-BIO-9**, restoration of mudflat, would reduce project impacts to a less than significant level. Therefore, impacts associated with alteration of an existing wetland habitat would be **less than significant with mitigation incorporated.**

Table 3.3-3. Temporary Impacts on Aquatic Resources (acres)

Study Area Feature	USACE Section 404 Non-Wetland Waters of the United States/ RWQCB Section 401 Non-Wetland Waters of the State	USACE Section 404 Wetland Waters of the United States/RWQCB Section 401 Wetland Waters of the State	USACE Section 10 Navigable Waters of the United States	CCC One-Parameter Wetlands
Ballona Lagoon and Grand Canal	0.092	0.012	0.056	0.092
Total	**0.092**	**0.012**	**0.056**	**0.092**

Source: ICF, 2016.

BIO-5. Would the project result in an interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species?

Construction of the Proposed Project would include installation of a cofferdam that would partially block the Grand Canal; however, hydrological connectivity between upstream and downstream would remain in place throughout construction. Because the study area does not contain any identified wildlife corridors, it would not result in interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species. Therefore, impacts on wildlife corridors would be **less than significant.**

3.3.3.5 Operational Impacts

The analysis below describes the temporary and permanent short-term and long-term direct and indirect impacts on vegetation communities and other sensitive biological resources anticipated as a result of project operation.

BIO-1. Would the project result in the loss of individuals, or the reduction of existing habitat, of a state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat?

The analysis below address potential impacts that could occur to biological resources and essential fish habitat during operation related to the loss or reduction of sensitive species and associated habitats as well as critical habitat important to their life cycle. As noted below, no impacts on special-status plants and wildlife or essential fish habitat would occur and therefore, no mitigation is required. **Less-than-significant impacts** on nesting birds and raptor foraging habitat would occur, and no mitigation is required.

Special-Status Plants and Wildlife

No impacts would occur to special-status plants (i.e., woolly seablite, southwestern spiny rush, and red sand verbena) or special-status wildlife (i.e., El Segundo blue butterfly, Belding's savannah sparrow, light-footed clapper rail, and California least tern) because the Project Site would be paved and include landscaping and open space uses that would not contain suitable habitat for these species. As a result, no impacts on individuals or populations would occur. The Grand Canal bank, which would be disturbed by construction of the diversion structure, would be restored to include native plant communities and species, based upon agency permit requirements. This would enhance the overall potential habitat for these species. Therefore, operation of the Proposed Project would not have a substantial adverse effect, either directly or through habitat modifications, or result in the loss of individuals, or the reduction of existing habitat, of a local, state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat. Therefore, **no impacts** on special-status plants would result, and no mitigation is required.

Nesting Birds

Less-than-significant impacts on nesting birds would occur during operation. The study area supports marginally suitable habitat for nesting birds, including ground-nesting birds, such as black-necked stilt and killdeer, as well as a habitat for a few species that commonly nest in structures and trees in developed areas. As discussed in Section 4.1 (Aesthetics), there are no trees proposed at the VAPP and landscaping would be limited due to operational and access needs. Although the landscaping and design for the proposed open space area has not been finalized, it is anticipated that some trees, landscaping, and grassy areas would be included. Because any tree trimming proposed within the open space area would need to occur in compliance with the *Migratory Bird Treaty Act* and *California Fish and Game Code* sections, impacts would be less than significant. Also, the additional habitat resulting from restoration of the Grand Canal slope that would be disturbed by construction of the diversion structure may provide additional habitat for ground-nesting birds. Therefore, impacts on nesting birds would be **less than significant**; no mitigation is required.

K:\Irvine\GIS\Projects\LABOE\00476 15\mapdoc\JD\Fig05 USACE.mxd Date: 10/5/2016 37937

Figure 3.3-2
USACE/RWQCB Jurisdictional Delineation Results Map
Venice Auxiliary Pumping Plant Project

Raptor Foraging

As indicated above, raptors are generally not expected to nest within the study area due to the disturbed and developed nature of the project and only limited foraging habitat is present. Because additional habitat resulting from restoration of the Grand Canal slope disturbed by construction of the diversion structure would be in place during operation, some additional foraging opportunities would result and would therefore be considered beneficial. As such, impacts on raptors would be **less than significant**; no mitigation is required**.**

Essential Fish Habitat

No designated Essential Fish Habitat is present within the study area; therefore; **no impacts** would occur during operation; no mitigation is required.

BIO-2. Would the project result in a loss of individuals or reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community?

No impacts on vegetation communities or an ESHA would occur during operation since none would be removed or adversely affected. Although the landscaping plan for the open space area has not been developed, the use of some native plants will be required in the plant palette. This would assist to ensure that the Proposed Project would not cause the loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community. It would also contribute to the overall habitat quality and quantity of the ESHA. Therefore, impacts on this sensitive vegetation community or ESHA would be **less than significant,** and no mitigation is required.

BIO-3. Would the project result in an interference with habitat such that normal species behaviors are disturbed (e.g., from the introduction of noise, light) to a degree that may diminish the chances for long-term survival of a sensitive species?

No natural habitats would experience direct permanent impacts during operation with the exception of habitat within Grand Canal and Ballona Lagoon that could be subject to permanent lighting installed on the new facility. Lighting at the VAPP and adjacent open space area may increase the amount of permanent ambient light within the Grand Canal and Ballona Lagoon. An increase in light could expose wildlife to increased detection and predation and could also deter some wildlife from utilizing the immediate area around the proposed facility lighting. However, the increase in ambient light resulting from operation of the project would be less than significant given the existing ambient light from surrounding residences and public infrastructure. The Proposed Project would be subject to City of Los Angeles lighting requirements and those contained in the Venice Community Plan (VCP) and Venice Local Coastal Program (VLCP), which would reduce the amount of ambient light spillover into the canal. Conditions contained in those documents require that lighting be maintained on-site and no spillover occur on adjacent sensitive land uses. Therefore, operation of the Proposed Project would result in **less-than-significant** impacts and would not diminish the chances for long-term survival of a sensitive species.

BIO-4. Would the project result in the alteration of an existing wetland habitat?

No impacts on an existing wetland habitat would occur during operation of the Proposed Project because none would be removed or altered as a result of project operations; therefore, the project would result in **less-than-significant** impacts with no mitigation is required**.**

BIO-5. Would the project result in an interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species?

The study area consists of a partial wildlife corridor and contains aquatic habitat connected to Marina Del Rey that provides refuge and foraging habitat. Project operation would not result in interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species because all facilities within the Grand Canal would be below existing grade. Therefore, impacts on wildlife corridors would be **less than significant**, and no mitigation is required.

3.3.4 Mitigation Measures

The following mitigation measures were developed to avoid or minimize the Proposed Project's potential impacts on biological resources and jurisdictional areas and are also contained in Appendix C of this EIR.

MM-BIO-1: Special-Status Plant Surveys

To confirm the presence or absence of special-status plant species within the disturbance footprint, a special-status plant survey shall be completed prior to construction. The focused survey shall be conducted by a qualified biologist during the appropriate blooming period, or when the plant is readily identifiable, prior to the start of construction activities. If any sensitive non-listed plant species is found, then the individuals shall be clearly identified and avoidance measures shall be utilized to the extent practical.

MM-BIO-2: Monitoring During Vegetation Removal

A qualified biologist shall monitor all vegetation removal and ground-disturbing activities, such as staging and grading, for the duration of the project to ensure that practicable measures are being employed to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species. When vegetation removal and ground-disturbing activities are not occurring, as-needed monitoring at the Project Site shall occur. Monitoring logs, as appropriate depending on project activities, shall be maintained for the duration of construction activities.

MM-BIO-3: Restoration of Vegetation within Grand Canal

Regarding the disturbance footprint within the Grand Canal, habitat along the bank shall be restored to its original condition by seeding, cuttings and/or container plant installation following construction. Habitat restoration shall be performed in coordination with regulating agencies (CCC, USACE, and RWQCB) and as required by agency permits. A habitat restoration plan shall be prepared and submitted to the Environmental Management Group for review and approval, prior to submittal to the agencies. The plan will include a native plant palette, and establishment period, as well as success criteria and monitoring requirements. In addition, a monetary contribution will be provided to the Grand Canal Restoration Project fund for wider restoration of the canal banks.

MM-BIO-4: Covered Disposal Containers

Work crews shall properly dispose of all garbage in covered containers to avoid attracting predators (such as crows and ravens) that could contribute indirectly to depredation of California least tern eggs and chicks in the nearby nesting colony.

MM-BIO-5: Water Quality Monitoring During Construction

Water quality shall be monitored by the qualified biologist or a water quality specialist to ensure that no substantial increases in turbidity occur during construction. The contractor shall ensure compliance with RWQCB Section 401 Water Quality Certification, USACE Section 404 authorization, applicable water-quality related Best Management Practices, and the project Storm Water Pollution Prevention Plan.

MM-BIO-6: Nesting Bird Survey

If construction commences during the bird breeding season (February 15 through August 31), a preconstruction survey for nesting birds shall occur within three days prior to construction activities by an experienced avian biologist. The survey shall occur within all suitable nesting habitat within the project impact area and a 500-foot buffer. If nesting birds are found, an avoidance area shall be established in consultation with the resource agencies as appropriate by a qualified biologist around the nest until a qualified avian biologist has determined that young have fledged or nesting activities have ceased. The Project Site shall be re-surveyed if there is a lapse in construction activities for more than seven days during the bird breeding season.

MM-BIO-7: Silt Fencing at Construction Limits

Construction limits shall be identified using silt fencing, which shall be installed under the supervision of a qualified biologist prior to the commencement of work. Construction personnel shall strictly limit their activities, vehicles, equipment, and construction materials to the project footprint, including designated staging areas, and routes of travel. The construction areas shall consist of the minimal area necessary to complete the Proposed Project. The fencing shall remain in place until the completion of all construction activities.

MM-BIO-8: ESHA Protection

Existing functions and values in ESHA shall be protected, enhanced, and restored as necessary to previous undisturbed conditions in accordance with applicable USACE, RWQCB, CCC, or City of Los Angeles permits and requirements.

MM-BIO-9: Restoration of Mudflats within Grand Canal

The temporary work area within Grand Canal within mudflat/open water shall be returned to pre-construction grade and contours following construction.

3.3.5 Significant Unavoidable Adverse Impacts

There are no significant unavoidable adverse impacts that would result with implementation of the Proposed Project either during construction or operation. All impacts would be less than significant with mitigation incorporated.

3.3.6 Cumulative Impacts

Based upon a review of Table 1-1, Related Projects List (see Chapter 1, Introduction of this EIR), none of these projects have resulted in, or are likely to result in, significant impacts to biological resources in the vicinity of the Proposed Project, either individually or cumulatively. With the implementation of the proposed mitigation measures identified above for the Proposed Project, no significant effects would occur on biological resources and no other known projects in the vicinity of the Proposed Project that, when considered together, would result in significant adverse impacts to the wildlife and habitats in the vicinity of the Project Site. Therefore, cumulative impacts related to biological resources would be less than significant.

3.4 Cultural Resources

This section identifies cultural resources present within the project area, evaluates the potential project-related impacts on those resources, and provides mitigation measures, as applicable. The survey of cultural resources was conducted under the provisions of Section 15064.5 of the California Environmental Quality Act (CEQA) Guidelines. The environmental setting information and analysis in this section are summarized from the *Cultural Resources Screening Memorandum*, 2015 and *AB 52 Consultation.* These technical reports are hereby incorporated by reference and included as Appendices E and F, respectively, of this environmental impact report (EIR).

As noted in the analysis below, with the implementation of a mitigation measure, direct and indirect impacts associated with cultural resources during construction and operation would be less than significant.

3.4.1 Regulatory Setting

Cultural resources fall within the jurisdiction of several levels of government. State and local jurisdictions provide the framework for the identification, documentation, and protection of such resources. The National Historic Preservation Act (NHPA), CEQA, California Public Resources Code (PRC) Section 5024, City of Los Angeles Cultural Heritage Ordinance (Los Angeles Administrative Code Section 22.130), and State Health and Safety Code (HSC) Section 7050.5/PRC Section 5097.9 are the primary laws that govern and affect the preservation of cultural resources of national, state, regional, and local significance.

3.4.1.1 National Register of Historic Places

To determine whether an undertaking could affect National Register of Historic Places– (NRHP-) listed or eligible properties, cultural resources (including archaeological, historical, and architectural properties) must be inventoried and evaluated for listing in the NRHP. For projects involving a federal agency, cultural resource significance is evaluated in terms of eligibility for listing in the NRHP. In order for a property to be considered to be included in the NRHP, it must meet the criteria for evaluation set forth in 36 Code of Federal Regulations (CFR) Part 60.4, as follows.

The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of design, setting, materials, workmanship, feeling, association, and:

a. That are associated with events that have made a significant contribution to the broad patterns of our history; or

b. That are associated with the lives of persons significant in our past; or

c. That embody the distinctive characteristics of a type, period, or method of construction or that represent the work of a master or that possess high artistic values or that represent a significant and distinguishable entity whose components may lack individual distinction; or

d. That have yielded, or may be likely to yield, information important in prehistory or history.

Among other criteria considerations, a property that has achieved significance within the last 50 years is not considered eligible for inclusion in the NRHP unless certain exceptional conditions are met.

3.4.1.2 State

California Environmental Quality Act

In accordance with Section 21084.1 of CEQA, the Proposed Project would have a significant adverse environmental impact if it, "causes a substantial or potentially substantial adverse change in the significance of an historical resource." Paleontological resources are also provided protection as historical resources, as discussed in State CEQA Guidelines Section 15064.5(a)(3).

Section 21084.1 defines historical resources as any resource listed or determined eligible for listing in the California Register of Historical Resources (CRHR). Properties listed or determined eligible for listing in the NRHP, such as those identified in the Section 106 process, are automatically listed in the CRHR, pursuant to 14 California Code of Regulations (CCR) Section 4851 (a)(1). Therefore, all historic properties under federal preservation law are automatically historical resources under state preservation law. Historical resources are also presumed to be significant if they are included in a local register of historical resources or identified as significant in a qualified historical resource survey.

State law in Title 14, CCR Section 4850, defines historical resource as follows:

> Any object, building, structure, site, area, place, record, or manuscript that is historically or archaeologically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural history of California.

For the purposes of CEQA, historical resource is further defined under PRC Section 15064.5 as a "resource listed, or determined eligible for listing, in the California Register."

Section 15064.5 of the State CEQA Guidelines sets forth the criteria and procedures for determining significant historical resources and the potential effects of a project on such resources. Generally, the lead state agency shall consider a historical resource to be historically significant if the resource meets any of the criteria for listing in the CRHR.

City statutes and guidelines specify how historical resources are to be managed in the context of projects such as the Proposed Project. Archival and field surveys must be conducted, and identified historical resources must be inventoried and evaluated against the Secretary of Interior Standards.

California Register of Historical Resources

NHPA mandated the selection and appointment in each state of a State Historic Preservation Officer (SHPO). Each SHPO is tasked with, among other duties, maintaining an inventory of historic properties. In California, the state legislature established additional duties for the SHPO. These include the maintenance of the CRHR. Established by PRC Section 5024.1(a) in 1992, the CRHR serves as "an authoritative guide in California to be used by state and local agencies, private groups, and citizens to identify the state's historical resources and to indicate what properties are to be protected, to the extent feasible, from substantial adverse change." According to PRC Section 5024.1(c), the CRHR criteria broadly mirror those of the NRHP. The CRHR criteria are found at PRC Section 5024.1(c) as follows.

An historical resource must be significant at the local, state, or national level, under one or more of the following four criteria:

1. It is associated with events that have made a significant contribution to the broad patterns of local or regional history, or the cultural heritage of California or the United States; or
2. It is associated with the live of persons important to local, California, or national history; or
3. It embodies the distinctive characteristics of a type, period, region, or method or construction, or represents the work of a master, or possesses high artistic values; or
4. It has yielded, or has the potential to yield, information important to the prehistory or history of the local area, California, or the nation.

The minimum age criterion for the CRHR, as with the NRHP, is 50 years. Properties less than 50 years of age may be eligible for listing in the CRHR if it can be demonstrated that sufficient time has passed to understand its historical importance. In addition to meeting one or more of the historical significance criteria, the resource must possess integrity. Integrity is defined as "the authenticity of an historical resource's physical identity evidenced by the survival of characteristics that existed during the resource's period of significance."

There are several ways for resources to be included in the CRHR. A resource can be listed in the CRHR based upon a nomination and public consideration process. Additionally, a resource that is subject to a discretionary action by a governmental entity will be evaluated for eligibility for the CRHR. As previously stated, properties listed in or formally determined eligible for listing in the NRHP are automatically listed in the CRHR.

California Environmental Quality Act—Tribal Cultural Resources

Recent legislation known as Assembly Bill 52 amended CEQA to add another category of cultural resource—Tribal Cultural Resources (TCRs). TCRs are defined as follows.

(a) "Tribal cultural resources" are either of the following:

(1) Sites, features, places, and objects with cultural value to descendant communities or cultural landscapes, that are any of the following:

(A) Included in the California Register of Historical Resources.

(B) Included in a local register of historical resources as defined in subdivision (k) of Section 5020.1.

(C) A resource deemed to be significant pursuant to criteria set forth in subdivision (c) of Section 5024.1.

(2) Sacred places including, but not limited to, Native American sanctified cemeteries, places of worship, religious or ceremonial sites, or sacred shrines that meet either of the following criteria:

(A) Listed on the California Native American Heritage Commission's Sacred Lands File pursuant to Section 5097.94 or 5097.96 for which a Native American tribe has submitted sufficient evidence demonstrating that the sacred places are of special religious or social significance to the Native American tribe or contain known graves and cemeteries of Native Americans.

(B) Listed or determined pursuant to criteria set forth in subdivision (g) of Section 5024.1 to be eligible for listing in the California Register of Historical Resources.

(b) A cultural landscape that meets the criteria of subdivision (a) is a tribal cultural resource to the extent that the landscape is geographically defined in terms of the size and scope of the landscape.

(c) A historical resource described in Section 21084.1, a unique archaeological resource as defined in subdivision (g) of Section 21083.2, or a "nonunique archaeological resource" as defined in subdivision (h) of Section 21083.2 may also be a tribal cultural resource if it conforms with the criteria of subdivision (a).

State Health and Safety Code, Section 7050.5/California Public Resources Code, Section 5097.9

State Health and Safety (HSC) Code Section 7050.5 and PRC Section 5097.9 contain provisions for the treatment of human remains contained in archaeological sites. Under HSC Section 7050.5, if human remains are discovered during any project activity, the county coroner must be notified immediately. If human remains are exposed, HSC Section 7050.5 states that no further disturbance shall occur until the county coroner has made the necessary findings as to origin and disposition pursuant to PRC Section 5097.98. Construction must halt in the area of the discovery of human remains, the area of the discovery shall be protected, and consultation and treatment shall occur as prescribed by law. If the remains are determined by the coroner to be Native American, the coroner is responsible for contacting the Native American Heritage Commission (NAHC) within 24 hours. NAHC, pursuant to Section 5097.98, will immediately notify those persons it believes to be most likely descended from the deceased person so they can inspect the burial site and make recommendations for treatment or disposal.

3.4.1.3 Local

City of Los Angeles Cultural Heritage Ordinance

The City of Los Angeles maintains a list of all sites, buildings, and structures that have been designated through the Cultural Heritage Ordinance as Historic-Cultural Monuments (HCMs).

Historic-Cultural Monument

Section 22.171.7 of the Cultural Heritage Ordinance states that an HCM is any site (including significant trees or other plant life on the site), building, or structure of particular historic of cultural significance to the city, including historic structures or sites in which the broad cultural, economic, or social historic of the nation, state, or community is reflected or exemplified; or that is identified with historic personages or with important events in the main currents of national, state, or local history; or that embodies the distinguishing characteristics of an architectural type specimen, inherently valuable for a study of a period, style, or method of construction; or a notable work of a master builder, designer, or architect whose individual genius influenced his or her age.

Any person may apply for the proposed designation of HCM, and the Cultural Heritage Commission determines whether or not the proposed designation merits consideration. If the Commission recommends approval of the application and it is included in the list of HCMs, no permit for the demolition, substantial alteration, or relocation of an HCM may be issued (Section 22.171.14) unless:

1. The Superintendent of Building or City Engineer determines that the demolition, relocation, or substantial alteration is necessary in the interest of the public health, safety or general welfare;
2. The substantial alteration complies with the Secretary of the Interior's Standards for Rehabilitation;

3. The substantial alteration protects and preserves the historic and architectural qualities and the physical characteristics that make the site, building, or structure a designated HCM; and
4. The proposed action is in compliance with CEQA (PRC Section 21000 et seq.).

City of Los Angeles Conservation Element

The Conservation Element of the City of Los Angeles General Plan (adopted September 2001) is designed to enhance, preserve, and protect the city's existing natural resources and other resources. The Conservation Element specifically addresses archaeological and paleontological resources in Section 3 of Chapter 2. The Conservation Element's paleontological objective is to "protect the city's archaeological and paleontological resources for historical, cultural, research and/or educational purposes." Moreover, its policy is to "continue to identify and protect significant archaeological and paleontological sites and/or resources known to exist or that are identified during land development, demolition or property modification activities."

3.4.2 Environmental Setting

The residences in the general vicinity of the Project Site date from 1964 to 2000 and are a mix of two- to three-story, single- and multi-family residences; there is a very large apartment complex at 3726 Via Dolce to the east of the Project Site. In addition to the mix of construction periods, the neighborhood displays a mix of architectural styles.

No sites or other resources are known from the immediate project area that are categorized as TCRs. The village sites and cemetery areas at Ballona Wetlands probably do meet this definition, but these areas are more than 2 miles southeast of the Project Site. There are also no known paleontological resources located on-site or within the immediate area. The Venice Canal System, including the Grand Canal is a City of Los Angeles Historic-Cultural Monument and is located adjacent to the Project Site.

3.4.2.1 Geological Setting

The project area is on the western margin of the boundaries of Ballona Lagoon, a broad, swampy marsh that existed in the area until twentieth century development (USGS 1896, 1924, 1934). This area is within the Southwest Sewer Subregion of the Framework EIR Element of the General Plan. The geologic formation underlying the project area is tentatively identified as clay and sand of existing marshlands (Dibblee 2007). These sediments are Holocene in age, and are less than 10,000 years old. Sediment in the project area may also derive from beach dune sands deposited along the lee of the Pacific Ocean, which are also Holocene in age (Dibblee 2007).

3.4.2.2 Prehistoric Background

The prehistoric occupation of Southern California is divided chronologically into four temporal phases, or horizons (Moratto 1984). Horizon I, or the Early Man Horizon, began at the first appearance of people in the region (approximately 12,000 years ago) and continued until about 5000 B.C. Although little is known about these people, it is assumed that they were semi-nomadic and subsisted primarily on game.

Horizon II, also known as the Millingstone Horizon or Encinitas Tradition, began around 5000 B.C. and continued until about 1500 B.C. The Millingstone Horizon is characterized by widespread use of milling stones (manos and metates), core tools, and few projectile points or bone and shell artifacts.

This horizon appears to represent a diversification of subsistence activities and a more sedentary settlement pattern. Archaeological evidence suggests that hunting became less important and that reliance on collecting shellfish and vegetal resources increased (Moratto 1984).

Horizon III, the Intermediate Horizon or Campbell Tradition, began around 1500 B.C. and continued until about A.D. 600–800. Horizon III is defined by a shift from the use of milling stones to increased use of mortar and pestle, possibly indicating a greater reliance on acorns as a food source. Projectile points become more abundant and, together with faunal remains, indicate increased use of both land and sea mammals (Moratto 1984).

Horizon IV, the Late Horizon, which began around A.D. 600–800 and terminated with the arrival of Europeans, is characterized by dense populations; diversified hunting and gathering subsistence strategies, including intensive fishing and sea mammal hunting; extensive trade networks; use of the bow and arrow; and a general cultural elaboration (Moratto 1984).

About 1 mile south of the project area is Ballona Wetlands, the remains of a major marshland that has been much studied by archaeologists. Several major prehistoric sites have been found within Ballona Wetlands, including extensive villages. The location of these sites includes the Westchester bluffs south of the wetlands, and raised terraces at the edge of the Ballona Wetlands overlooking Ballona Creek. The mouth of Ballona Wetlands, a setting similar to the project area, does not encompass any known sites.

3.4.2.3 Ethnographic Background

The project area lies within the territory of the Gabrielino Native American people (Bean and Smith 1978). The Gabrielino are characterized as one of the most complex societies in native Southern California, second perhaps only to the Chumash, their coastal neighbors to the northwest. This complexity derives from their overall economic, ritual, and social organization (Bean and Smith 1978:538; Kroeber 1925:621).

The Gabrielino, a Uto-Aztecan (or Shoshonean) group, may have entered the Los Angeles Basin as recently as 1500 Before Present (B.P.). In early protohistoric times, the Gabrielino occupied a large territory including the entire Los Angeles Basin. This region encompasses the coast from Malibu to Aliso Creek, parts of the Santa Monica Mountains, the San Fernando Valley, the San Gabriel Valley, the San Bernardino Valley, the northern parts of the Santa Ana Mountains, and much of the middle to the lower Santa Ana River. They also occupied the islands of Santa Catalina, San Clemente, and San Nicolas. Within this large territory were more than 50 residential communities with populations ranging from 50 to 150 individuals. The Gabrielino had access to a broad and diverse resource base. This wealth of resources, coupled with an effective subsistence technology, well-developed trade network, and ritual system, resulted in a society that was among one of the most materially wealthy and culturally sophisticated cultural groups in California at the time of contact.

3.4.2.4 Historic Background

Spanish occupation of California began in 1769, at San Diego. Mission San Gabriel was established in the Los Angeles Basin in 1771 and the Los Angeles Pueblo was established as a civilian settlement on September 4, 1781. This village housed 44 people, with a military guard of four soldiers (Dillon 1994).

Mexico rebelled against Spain in 1810, and by 1821 Mexico, including California, achieved independence. In 1833, Mexico declared an end to the Missions and secularized the religious order's land holdings. The Mexican Republic began to grant private land to citizens to encourage immigration to California. Huge land grant ranchos took up large sections of land in California. The project area was included in Rancho La Ballona, granted to Agustin Machado and Felipe Talamantes in 1839.

Cattle ranching came to overshadow the agricultural economy in the region during the Mexican Period, and industries and trade grew around this shift. San Pedro, south of Los Angeles, became a major port for export of tallow and hides to Boston and Europe.

At the conclusion of the Mexican-American War in 1848, Alta California was ceded to the United States. Four years later, in October 1852, the Hispanic families owning Rancho La Ballona filed their claims with the Land Commission for the confirmation of their grant. As required by U.S. law, the Rancho La Ballona grant was surveyed by Henry Hancock in 1858. The grant rancho lasted until 1865, when Agustin Machado died, and numerous heirs were granted small parcels.

The land boom of the 1880s heavily affected Los Angeles. Throughout the 1890s and into the early 1910s and 1920s, as the old ranchos were bought up and subdivided by new Euroamerican owners, the cities of Santa Monica, Culver City, Venice, and Inglewood and the communities of Playa del Rey, and Westchester were platted and the land quickly sold off. The railroad came through the area in the 1890s. In 1892, the California Central Railroad, Santa Fe Railroad's local subsidiary, completed a spur line from old "Port Ballona" tracks to Ocean Park. By the end of the century, the line was known as the Southern California Railroad.

The following section is excerpted from the historic context prepared for the *Venice Community Plan Area Historic Resources Survey Report* in support of SurveyLA (Historic Resources Group 2015).

> …The project area was first developed at the turn of the 20th century. In 1891, tobacco magnate and real estate developer Abbot Kinney and his business partner, Francis G. Ryan, purchased a 1.5 mile-long strip of beachfront land located south of Santa Monica. The 275-acre parcel had originally comprised a portion of Rancho La Ballona and was initially settled by the Machado and Talamantes families in the early 1800s. The northern third of the acreage was located in the city of Santa Monica. However, the remainder of the land, located south of present-day Marine Street, was situated in county territory and consisted of wetlands, with sand dunes and marshes that often flooded in the winter.
>
> Kinney and Ryan turned their attention to the northern portion of the tract, where they developed a resort community which eventually came to be known as Ocean Park. Abbot Kinney would likely have dedicated his career to developing Ocean Park; however, in 1898, Francis Ryan died suddenly at the age of 47. Kinney eventually acquired three new business partners in 1902: Alexander Fraser, Henry Gage, and George Merritt Jones. Competition from other developers motivated Kinney and his partners to make improvements to the community of Ocean Park and to expand their development further south into the land comprising present-day Venice… The majority of the land was subdivided as part of the Golden Bay tract, which was recorded in May 1902. The land to the south, extending from Brooks Court down to Westminster Court, was also subdivided by Kinney, Fraser, Gage, and Jones as the Country Club tract, recorded in April 1903…
>
> …Further inland, to the east of Main Street, development occurred in a piecemeal fashion. Individual developers purchased blocks of land from larger tracts, such as the Santa Fe and Ocean Tracts, and subdivided them into smaller parcels which were more suitable for residential development. In this way, developers were able to capitalize on the area's proximity to nearby Ocean Park amenities. Notable inland residential subdivisions included the Ocean Park Villa Tract and the Ocean Park Villa Tract No. 2, both of which were developed in 1903 near the Ocean Park Country Club. Retired banker

and real estate developer E.J. Vawter also purchased a block of land which he developed as a botanical estate dedicated to the cultivation of carnations. The property's prior use was commemorated when Vawter later subdivided the land for residential development as the Carnation Tract.

By 1904, Kinney found himself at odds with his partners. Among other matters, the four men disagreed on how the unincorporated wetlands comprising the southern portion of their holdings should be developed. Abbot Kinney believed that to successfully develop the unincorporated area, it would be necessary to create an independent municipality south of Marine Street. The four men decided to dissolve their partnership and go their separate ways; Kinney won a coin toss employed to divide up the company's assets and selected the southern portion of the tract. Several months later, those residents living south of Marine Street, in the unincorporated portion of the Ocean Park development, voted to establish the separate city of Ocean Park. It was within this community that Abbot Kinney created his most successful development, Venice of America…

…In 1905, a subdivision map was recorded for the Venice of America tract which reflected Abbot Kinney's initial plans for his new development. The plan for the tract was comprehensive and included areas dedicated to recreational, commercial, and residential properties. At the beach, a 1,400-foot pier was constructed. Included among its various attractions were an auditorium, a dance hall, and a nautical-themed restaurant that resembled a ship. A hot saltwater plunge was situated on the beach just north of the pier; in 1908 the plunge was expanded to become the Venice Surf Bathhouse. A boardwalk was planned along present-day Ocean Front Walk, which was noted on Kinney's presentation map as the "Pacific Promenade." Windward Avenue, which extended from the beach to the Bathing Lake and canals further east, was intended to serve as the primary commercial corridor. Visitors and tourists arriving in Venice via streetcar disembarked at Windward, which provided their first glimpse of Abbot Kinney's "Venice-of-America." As a result, Windward Avenue played an important role in establishing the character of Kinney's development in Venice.

In an effort to create a cohesive aesthetic in keeping with his vision for the resort town, Kinney stipulated that all building exteriors in the Venice business district be constructed "in harmony with the 'Venetian Renaissance' style." He commissioned architects Norman Marsh and Clarence Russell to design the principal buildings for Venice; the two men modeled their designs after Italy's Piazza San Marco, whose buildings featured enclosed colonnaded walkways. In keeping with Kinney's vision for a town which resembled the Italian original, the residential area of Venice –known as the "canal district" –was distinguished by a network of man-made saltwater canals. The lateral canals in the residential area led to the Grand Canal, which emptied directly into the sea. As much of the land on which Venice was constructed was situated below sea level, the canal waters were controlled by the rising and falling of ocean tides, which flushed the waterways. Distinctive arched footbridges, designed by Italian metal sculptor Felix Peano, spanned the canals and connected the four islands of residential lots. In anticipation of the influx of visitors which would likely vastly exceed the available accommodations, land had also been set aside south of the Grand Canal for the erection of a tent city, where rustic "cottages with canvas sides"–or as Kinney noted on his presentation map, "Venetian Villas"–could be rented for overnight stays…

…Although the canals were still under construction, Venice of America officially opened to the public on July 4, 1905. By this time, several key commercial buildings had been completed, including the Bank of Venice at the intersection of Windward and Pacific avenues. Early buildings were designed in the Mediterranean Revival style, reflecting Kinney's mandate, and featured elaborate arcades which extended along the north side of Windward Avenue from Ocean Front Walk to Pacific Avenue. The Mediterranean Revival style continued to be employed for new construction through the early 1920s; however, by the end of the decade, examples of commercial vernacular buildings were introduced to the district…

…Following a successful opening season, in 1906 Abbot Kinney began to expand the city services in Venice. Construction commenced on a city hall (now designated a City Historic-Cultural Monument) and a fire station, which was designed by John Gabrovck and completed that same year. An Edison Electric Company facility was later constructed in 1910…

> …By 1907, the Venice of America development had become the nexus of the city of Ocean Park. In fact, the area's success and its potentially negative impact on the surrounding business developments of Ocean Park was keenly felt by Ocean Park businessmen, sparking resentment and discord. It was these "conflicting business interests," as Jeffrey Stanton describes, that triggered a feud between the two entities. "The basic problem," Stanton observes, "was that two rival communities were growing up in one municipality."
>
> After months of real estate and political battles, Abbot Kinney launched a campaign to "dis-incorporate" Venice of America from the surrounding community of Ocean Park. While community sentiment within Venice of America was clearly in Kinney's favor, his efforts failed to muster the two-thirds majority required to prevail in the public election. Venice of America remained a part of the Ocean Park community; in 1911, the entire community was renamed Venice…
>
> …While business development may have been controversial, residential developers in surrounding areas of Ocean Park began to devise ways to capitalize on the resort's success. Soon, a second set of six canals appeared just to the south of Venice of America. Developed by the Short Line Beach Company in 1905-1906, the subdivision was known as the Venice Canal Subdivision. The Short Line Beach Company continued to divide land further south down the peninsula, as did the Los Angeles Pacific Railroad Company and Kinney's former business partners. The Silver Strand tract, developed by Alexander Fraser, Henry Gage, and George Merritt Jones in 1905, featured lots oriented around a Grand Canal spanned by bridges… Although the peninsula was originally subdivided by several different developers, the streets were later renamed in 1964 to reflect a nautical theme; east-west streets along the peninsula are arranged alphabetically from north to south…

The project area reflects this later period of development and subdivision. Although there may have been some residential development in the vicinity of the project area previous to 1964, the earliest building is the Venice Pumping Plant, which dates from the late 1950s. Residential development is spotty, beginning in the mid-1960s and continuing on through 2000.

3.4.2.5 Identification and Evaluation of Cultural Resources

Methodology

Archaeological Resources

The study area was defined as those parcels that would encompass all project components (see Figure 2-2, Project Location Map, in Chapter 2 [Project Description] of this EIR), including temporary construction activities. In order to identify and evaluate archaeological resources, a records search and pedestrian field survey were conducted. Additional background research was conducted to establish the context and setting of the project area.

Tribal Cultural Resources

NAHC was contacted on November 2, 2015 with a request for a Sacred Lands File search and a list of Native American contacts for the area. Once this list was received, the City contacted by letter or e-mail the groups on the NAHC list and a City-maintained list. A total of two replies were received, from the Gabrieleño Band of Mission Indians – Kizh Nation and the Fernandeño Tataviam Band.

Historical Resources

The study area was defined as those parcels immediately adjacent to the Project Site described in the project description (see Figure 2-2, Project Location Map, in Chapter 2 [Project Description] of this EIR) and would encompasses all project components, including temporary construction activities. The study area includes residential properties on Canal Court, Hurricane Street, Marquesas Way, and Via Dolce, and encompasses a section of the Venice Grand Canal.

In order to identify and evaluate historical resources, a multi-step methodology was utilized. Record searches for previous documentation of identified historic resources were conducted, including listings in the NRHP, determinations of eligibility for NRHP listings, and the City of Los Angeles' historic resource inventories. An intensive survey, including photography and background research, was then made of the study area. Additional background and site-specific research was conducted in order to evaluate the properties within their historic context. CRHR and City of Los Angeles criteria were employed to assess the significance of the properties.

Survey Results

The records search included a review of all available archaeological and historical resources reports and site records concerning properties directly bordering the entire project area and a 0.5-mile surrounding record search area. Two studies were previously conducted within portions of the project area. No archaeological sites have been previously recorded within the boundaries of the project area; one City of Los Angeles HCM is present in the project area, the Venice Canal System, HCM #270; and furthermore, there no TCR's are on the site. Two historic cultural resources are encompassed in the 0.5-mile buffer area—the Venice Canal Historic District and the Warren Wilson Beach House.

The cultural resources survey process undertaken for the Proposed Project was conducted per SHPO instructions, which gives a 45-year threshold for surveying properties for significance. Those properties that were of post-1970 construction (under 45 years of age) were not documented unless they potentially exhibited "exceptional" importance.[1]

Archaeological Resources

A records search was conducted on September 1, 2015, at the South Central Coastal Information Center (SCCIC) at California State University, Fullerton. SCCIC is a branch of the California Historical Resources Information Center, which maintains California's official records of previously recorded cultural resource studies and recorded archaeological sites for Ventura, Los Angeles, Orange, and San Bernardino Counties. The SCCIC records search included the project area and a 0.5-mile buffer.

No archaeological resources are recorded in the project area.

A review of SCCIC's records indicates that 15 previous cultural resource studies have been conducted within a 0.5-mile radius of the project. Of these, two studies are included the project area; for those studies, no resources were recorded within the project area boundaries. Most studies observed no prehistoric or historic archaeological resources or isolated artifacts. Moreover, the 13 studies within the 0.5-mile buffer area produced positive results for just two cultural resources. However, the search indicated that no prehistoric archaeological sites are included on the Archaeological Determination of Eligibility list.

A comprehensive archaeological pedestrian survey of the project footprint was conducted on August 20, 2015. This area was surveyed in order to inspect for and identify any previously undiscovered cultural resources. The pedestrian survey consisted of walking transects 3 meters (10 feet) apart in an east/west orientation. Ground surface visibility was fair with the surface somewhat obscured by vegetation, resulting in approximately 80% surface visibility. No archaeological resources were identified during the field survey.

[1] As defined in the National Register Bulletin, p. 42 (Criterion Consideration G: Properties That Have Achieved Significance within the Past Fifty Years).

Tribal Cultural Resources

NAHC reviewed its Sacred Lands File and indicated in a letter sent to ICF International (ICF) on November 3, 2015 that there were Native American resources recorded in the area. However, the site numbers provided were all for sites in Ballona Wetlands, not the project area. NAHC recommended contacting six Native American groups in the area. The City contacted by letter or e-mail nine groups from contacts on the NAHC list and a City-maintained list.

Groups contacted are listed below.

- Gabrielino Tongva Indians of California Tribal Council
  Robert F. Dorame, Tribal Chair, Cultural Resources
- Tongva Ancestral Territorial Tribal Nation
  John Tommy Rosas, Tribal Administrator
- Fernandeño Tataviam Band of Mission Indians
  Rudy Ortega Jr., President
- Gabrieleño Band of Mission Indians – Kizh Nation
  Andrew Salas, Chairperson
- Gabrielino-Tongva Tribe
  Linda Candelaria, Co-Chairperson
- Gabrielino/Tongva Nation
  Sam Dunlap, Cultural Resources Director
- Gabrielino/Tongva San Gabriel Band of Mission Indians
  Anthony Morales, Chairperson
- San Fernando Band of Mission Indians
  John Valenzuela, Chairperson
- Soboba Band of Luiseño Indians
  Joseph Ontiveros, Cultural Resource Director

The Gabrieleño Band of Mission Indians – Kizh Nation replied on November 30, 2015, stating that the area is sensitive and in the location of a village known to have existed in Ballona Wetlands. Native American monitoring was recommended for the project; no evidence was provided that the project footprint itself is within a TCR.

A response was received from the Fernandeño Tataviam Band on December 1, 2015 stating that the project area was outside of Tataviam territory, and that the Band did not wish to consult on the project. The Soboba Band replied on December 21, 2015, stating that it had no specific concerns about the project. The Soboba Band stated that it defers to Gabrielino representatives closer to the project.

Historical Resources

Within the study area, there are no NRHP-listed properties, no buildings were determined eligible for listing in the NRHP or the CRHR, and one property is listed as a HCM. As previously stated, properties listed in or formally determined eligible for listing in the NRHP are automatically listed in the CRHR.

The Venice Canal System, HCM #270, was designated on July 15, 1983; the Grand Canal is included as part of this historical resource. The Venice Canal System was designated as an HCM for its association with "an historic personage," specifically, as the creation of developer Abbot Kinney. Therefore, the Venice Canal System is important as an achievement of Kinney; it is not eligible as an HCM for reflecting the broad cultural, economic, or social history of the nation, state, or community; for embodying characteristics of an architectural type specimen inherently valuable for a study of a period, style, or method of construction; or for being a notable work of a master builder, designer, or architect whose individual genius influenced his or her age.

While portions of the Grand Canal north of Washington Street are associated with the NRHP-listed Venice Canal District, the portion of the Grand Canal within the study area is not within the NRHP-listed historic district boundaries and was intentionally omitted when the district was nominated to the NRHP in 1980.

Of the six parcels immediately adjacent to the Project Site, only two contain any buildings or structures that were constructed prior to 1970. Please see Table 3.4-1 below for a list of properties in the study area.

Table 3.4-1: Properties in the Study Area

APN	Street Address	Date of Construction
4225008009	3809 S. Esplanade (3809 Gran Corso), Los Angeles, CA 90292	1977
4225008036	129 Hurricane Street, Los Angeles, CA 90292	1992
4225010017	120 Hurricane Street, Los Angeles, CA 90292	1968
4225010900	140 E. Hurricane Street (134 E. Hurricane, 3901 S. Esplanade), Los Angeles, CA 90292	Circa 1956–60 (1957)
4225013157	3811 Via Dolce, Los Angeles, CA 90292	1989
4225013152	3815 S. Via Dolce, Los Angeles, CA 90292	2000

Building dates were acquired using the Zoning Information and Map Access System, additional information available at City of Los Angeles Department of Building and Safety online (http://ladbs.org/LADBSWeb/online-building-records.jsf), and at City of Los Angeles Office of Historical Resources.

Two buildings meet the age criteria, neither one of which has previously been evaluated for eligibility to the Los Angeles HCM list, CRHR, or NRHP. In researching the history of the development of this community, the Historic Resources Survey Report for the Venice Community Plan Area, prepared as part of the SurveyLA process undertaken by the City of Los Angeles Department of City Planning's Office of Historic Resources, was consulted. Additional research was conducted in January and February 2015 at HistoricPlacesLA.com, the Los Angeles Public Library online research databases, including its Photo Collection, the Department of Water & Power Photo Archive, and the California Index.

120 Hurricane Street was constructed in 1968. It is a two-story, multi-family residence that was designed in a Contemporary style with some fanciful decorative balcony entablature. It has a stucco exterior and a flat roof, and the open bay garage is located on the first story of the primary façade. The primary façade faces north onto Hurricane Street. Above the bay openings are two concrete balconies with metal balustrades, metal posts, and arched openings. Between the balconies is a

single roundel window. The south elevation overlooks the Ballona Wetlands and the associated pedestrian walkway. The second story of the south elevation has a cantilevered balcony with the same balustrade design as the north elevation. The balcony shelters a first-floor patio area. There is a wood picket fence surrounding the small backyard. Most of the visible windows appear to be original, multi-pane metal sash. There have been some replacement windows, including sliding doors to the balconies.

Looking southwest at 120 Hurricane Street, from the corner of Canal Court and Hurricane Street. Photo taken on August 19, 2015 (ICF).

This property likely retains integrity from the original period of construction; however, it does not embody the distinctive characteristics of a type, period, or method of construction. The Contemporary style of this property is common to both the area and the era, and the arched openings of the balconies do not indicate the work of a master or the presence of high artistic value. Research did not indicate that this individual property has an association with any persons or events that are important or have made significant contributions to the broad patterns of local or regional history. Therefore, 120 Hurricane Street is not eligible for the CRHR under Criteria A, B, or C.

The Venice Pumping Plant is surrounded by a 6-foot high wall with a concrete base and metal siding perched on top, portions of which were constructed in 2013. Located in the residential neighborhood within the Ballona Lagoon West subarea of Venice, the building is surrounded on two sides by water. On the east is the Grand Canal and on the south is the Ballona Wetlands. The property wall abuts the pedestrian sidewalk that separates the property from the water. An original building permit was not located during the research phase; other sources have indicated a general building period between 1956 and 1960, while the project description (see Chapter 2) states that it was constructed in 1957. The industrial building is two stories, with a smooth concrete exterior that is bare of decoration save horizontal groves approximately 4 feet apart. It has an irregular footprint.

The property itself houses a control facility, five pumps, a control center, emergency generators, and other associated equipment. This property was most recently upgraded in 1987.

Looking northwest at 140 Hurricane Street: Venice Pumping Plant. View from Via Dolce. Photo taken on August 19, 2015 (ICF).

No original photographs of the property were located during the research phase and, therefore, it is not clear how much integrity remains from the original period of construction. Many industrial civic buildings, such as pumping plants and switching stations, were designed in popular architectural styles in Los Angeles between the 1910s and the 1950s, but there is no indication that the Venice Pumping Plant's architecture style was specifically associated with its type or period of construction. Although this is considered to be the largest of the City's pumping plants, no written documentation that discusses the importance of its size and/or location was discovered during the research phase. There is no indication that this property was designed specifically to relate to its location, or to reflect its particular use. It is unknown who designed or engineered this property, except that it was constructed by the Department of Public Works. Research did not indicate that this individual property has an association with any persons or events that are important or have made significant contributions to the broad patterns of local or regional history. Therefore, the Venice Pumping Plant is not eligible for the CRHR under Criteria A, B, or C.

3.4.3 Environmental Impact Analysis

This section outlines the methodology, evaluation, and impacts for archaeological and historical resources. It is intended to assist in the evaluation and conclusions of the impact analysis provided below and in the formation of required mitigation measures.

3.4.3.1 Screening Analysis

As noted in Section Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.4.3.2 Thresholds of Significance

City of Los Angeles CEQA Thresholds Guide

The 2006 *L.A. CEQA Thresholds Guide* states that the following impact significance factors shall apply to archaeological and historical resources.

Archaeological Resources

The project would have a significant impact on archaeological resources if it could disturb, damage, or degrade an archaeological resource or its setting that is found to be important under the criteria of CEQA because it:

- Is associated with an event or person of recognized importance in California or American prehistory or of recognized scientific importance in prehistory;
- Can provide information that is both of demonstrable public interest and useful in addressing scientifically consequential and reasonable archaeological research questions;
- Has a special or particular quality, such as the oldest, best, largest, or last surviving example of its kind;
- Is at least 100 years old and possesses substantial stratigraphic integrity; or
- Involves important research questions that historical research has shown can be answered only with archaeological methods.

Historical Resources

The project would have a significant impact on historical resources if it would result in a substantial adverse change in the significance of a historical resource. A substantial adverse change in significance occurs if the project involves:

- Demolition of a significant resource;
- Relocation that does not maintain the integrity and significance of a significant resource;
- Conversion, rehabilitation, or alteration of a significant resource that does not conform to the Secretary of the Interior's Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings; or
- Construction that reduces the integrity or significance of important resources on the site or in the vicinity.

CEQA Appendix G

In accordance with Appendix G of the State CEQA Guidelines, the project would have a significant impact related to cultural resources if it would:

- Cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5;
- Cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 15064.5; or
- Disturb any human remains, including those interred outside of formal cemeteries.

Tribal Cultural Resources

The project would have a significant impact related to TCRs if it would:

- Cause a substantial adverse change in the significance of a site, feature, place, cultural landscape, sacred place, or object with cultural value to a California Native American Tribe that is listed or determined eligible for listing on the California Register of Historical Resources, listed on a local historical register, or otherwise determined by the lead agency to be a tribal cultural resource.

3.4.3.3 Construction Impacts

The analysis below describes the temporary and permanent impacts on cultural resources as a result of the Proposed Project during construction.

Archaeological Resources

CUL-1. Would the project disturb, damage, or degrade an archaeological resource or its setting, or otherwise cause a substantial adverse change in the significance of an archaeological resource?

No archaeological resources have been recorded in the project area. A survey of the project area located no archaeological resources. Research determined that this area was marshland and beach dunes adjacent to the outlet of Ballona Creek at the Pacific Ocean prior to modern development; this setting is unlikely to have preserved prehistoric archaeological resources due to constant erosion and deposition. These marshland and beach dune sediments have been substantially altered by twentieth century development, as the project area has been leveled and filled to create part of the community of Venice and the associated canals. Based on the setting and the level of previous disturbance, the potential for construction activities to disturb, damage, or degrade an archaeological resource or its setting is low. However, in the unlikely event that previously undisturbed archaeological resources are encountered during construction, impacts to these resources could be significant. With implementation of Mitigation Measure MM-CUL-1, which requires stopping work and treating any cultural resources that are discovered, impacts to archaeological resources would be reduced to **less than significant with mitigation**.

CUL-2. Would the project disturb any human remains, including those interred outside of formal cemeteries?

No human remains are known to exist in the project area, and the location does not encompass any formal cemeteries. Because the Project Site is situated on beach sands and marshland clays, there is a very low potential for prehistoric human remains to be present. While the uncovering of human

remains is not anticipated, if they are discovered, HSC Section 7050.5 requires that further disturbances and activities shall cease in any area or nearby area suspected to overlie remains, and the county coroner be contacted. Pursuant to PRC Section 5097.98, if the remains are thought to be Native American, the coroner shall notify NAHC, who shall then notify the Most Likely Descendant. Further provisions of PRC Section 5097.98 are to be followed as applicable.

Therefore, through compliance with existing regulations, impacts on human remains due to construction of the Proposed Project would be **less than significant** and no mitigation measures are required.

Historical Resources

CUL-3. Would the project result in a substantial adverse change in the significance of a historical resource due to demolition, relocation, conversion, rehabilitation, or alteration of a historical resource?

The Proposed Project includes the construction of a permanent submerged diversion structure that would connect the Coastal Interceptor Sewer, located in the Grand Canal, to the proposed VAPP. A temporary cofferdam in the Grand Canal would need to be constructed in order to make this connection. The Grand Canal, which is the only historical resource in the study area, meets HCM criteria for designation for its association with Abbot Kinney and the development of the "Venice of America." Although a coffer dam would be situated in the Grand Canal during the construction phase of the Proposed Project, it would not result in a substantial adverse change in the significance of this historical resource. The Grand Canal is significant for its association with Abbot Kinney, and this association would not be affected by the temporary submersion of a structure in the Canal itself. The temporary cofferdam would not remain in the water following construction of the diversion structure, which would be completely submerged below the bottom of the Grand Canal. Therefore, impacts during construction would be **less than significant** and no mitigation measures are required.

Tribal Cultural Resources

CUL-4. Would the project cause a substantial adverse change in the significance of a site, feature, place, cultural landscape, sacred place, or object with cultural value to a California Native American Tribe that is listed or determined eligible for listing on the California Register of Historical Resources, listed on a local historical register, or otherwise determined by the lead agency to be a tribal cultural resource?

TCR consultations were completed. No responses received from Native American groups suggest there are TCRs in the project footprint. No sites or other resources are known in the immediate project area that could be categorized as TCRs. The lack of known TCRs and the low potential for discovery of such resources indicates that construction would not affect TCRs and cause a substantial adverse change in the significance of a historical resource as defined in Section 15064.5.

No TCRs containing human remains and no human remains in general are known to exist in the project area, and the location does not encompass any formal cemeteries. Because the Project Site is situated on beach sands and marshland clays, there is a very low potential for prehistoric human remains to be present. While the uncovering of human remains is not anticipated, if they are discovered, HSC Section 7050.5 requires that further disturbances and activities shall cease in any

area or nearby area suspected to overlie remains, and the county coroner be contacted. Pursuant to PRC Section 5097.98, if the remains are thought to be Native American, the coroner shall notify NAHC, who shall then notify the Most Likely Descendant. Further provisions of PRC Section 5097.98 are to be followed as applicable. Therefore, through compliance with existing regulations, construction impacts on any TCRs containing human remains would be **less than significant** and no mitigation measures are required.

3.4.3.4 Operational Impacts

The analysis below describes the temporary and permanent impacts on cultural resources anticipated as a result of the Proposed Project during operation. The analysis below evaluates potential impacts, based upon the applicable threshold of significance.

Archaeological Resources

CUL-1. Would the project disturb, damage, or degrade an archaeological resource or its setting, or otherwise cause a substantial adverse change in the significance of an archaeological resource?

Operation of the project would not involve any ground-disturbing activities. Therefore, there would be no potential to disturb, damage, or degrade an archaeological resource or its setting. **No operational impacts** on archeological resources would occur and no mitigation measures are required.

CUL-2. Would the project disturb any human remains, including those interred outside of formal cemeteries?

No human remains are known to exist in the project area, and the location does not encompass any formal cemeteries. Because the Project Site is situated on beach sands and marshland clays, there is a very low potential for prehistoric human remains to be present. As a consequence and because operation of the project would not involve any ground-disturbing activities, **no operational impacts** on human remains would occur and no mitigation measures are required.

Historical Resources

CUL-3. Would the project result in a substantial adverse change in the significance of a historical resource due to demolition, relocation, conversion, rehabilitation, or alteration of a historical resource?

The only historical resource in the study area is the Grand Canal, which meets the HCM criteria for designation for its association with Abbot Kinney and the development of the "Venice of America." Once constructed, the diversion structure within the Grand Canal would be located below grade and would not protrude within the water column. Operation of the Proposed Project would not involve activities that could result in the demolition, relocation, conversion, rehabilitation, or alteration of the Grand Canal. Therefore, **no impacts** during operation would occur and no mitigation measures are required.

Tribal Cultural Resources

CUL-4. Would the project cause a substantial adverse change in the significance of a site, feature, place, cultural landscape, sacred place, or object with cultural value to a California Native American Tribe that is listed or determined eligible for listing on the California Register of Historical Resources, listed on a local historical register, or otherwise determined by the lead agency to be a tribal cultural resource?

As noted above, no responses that have been received from Native American groups suggest there are TCRs in the project footprint. No sites or other resources are known in the immediate project area that could be categorized as TCRs. Additionally, operation of the project would not involve ground disturbing activities; therefore, operation of the project would not disturb prehistoric human remains. Therefore, the project is **not likely to cause a substantial adverse change** in the significance of a TCR and no mitigation measures are required.

3.4.4 Mitigation Measures

The following mitigation measure was developed to avoid or minimize the Proposed Project's potential impacts on cultural resources and is also contained in Appendices E and F of this EIR.

MM-CUL-1: Unanticipated Archaeological and/or Tribal Cultural Resource Discoveries

In the unlikely event that any prehistoric artifact of historic period materials or bone, shell, or nonnative stone is encountered during construction, work shall be immediately stopped, the area secured, and work relocated to another area until the found materials can be assessed by a qualified archaeologist. Examples of such cultural materials might include historical trash pits containing bottles and/or ceramics; or structural remains or concentrations of grinding stone tools such as mortars, bowls, pestles, and manos; chipped stone tools such as projectile points or choppers; and flakes of stone not consistent with the immediate geology such as obsidian or fused shale. If the Archeologist determines that an artifact may qualify as a tribal cultural resource, a Native American monitor shall be consulted. The contractor shall stop construction within 30 feet of the exposure of these finds until a qualified archaeologist can be retained to evaluate the find (see 36 CFR 800.11.1, 14 CCR 15064.5(f) and PRC § 21084.3 (b).) If the resources are found to be significant, they shall be avoided or impacts shall be mitigated consistent with Section 106, State Historic Preservation Officer Guidelines, and/or Assembly Bill 52.

3.4.5 Significant Unavoidable Adverse Impacts

No significant unavoidable adverse impacts on archaeological, historical or tribal cultural resources would occur.

3.4.6 Cumulative Impacts

3.4.6.1 Archaeological Resources

The Proposed Project would result in no operational impacts on archaeological resources. Based on the setting and the level of previous disturbance, the potential for construction activities to disturb, damage, or degrade an archaeological resource or its setting is low. Additionally, if archaeological resources are encountered, Mitigation Measure MM-CUL-1 would reduce potential project-related

construction impacts to less than significant. The incremental effects of the Proposed Project, after mitigation, would not contribute to a significant adverse cumulative impact on archaeological resources.

3.4.6.2 Tribal Cultural Resources

The Proposed Project would have no impacts on TCRs, because no such resources are present within the project footprint, based on information received to date. Therefore, the project would not contribute to a significant adverse cumulative impact on TCRs.

3.4.6.3 Historical Resources

The only potential impacts to a historical resource (the Grand Canal) would occur during construction and those impacts would be less than significant. Consequently the study area for cumulative impacts would encompass other projects in the area that could affect the canal. Based upon a review of projects contained within Table 1-1, Related Projects List (see Chapter 1, Introduction of this EIR), none of the projects listed, including the Venice Dual Force Main would (which would be constructed underneath the Grand Canal [at Esplanade and Hurricane Street]) would result in significant cumulative effects on the Grand Canal. Similarly, the Proposed Project would also not result in significant cumulative effects on the Grand Canal.

3.5 Geology and Soils

This section describes the affected environment and regulatory setting for the geologic and soil characteristics of the Project Site. This section also describes the potential geologic and soil impacts that would result from implementation of the Proposed Project and, where necessary to reduce potentially significant impacts, provides mitigation measures to reduce such impacts to less than significant levels. The environmental setting information and analysis in this section is summarized from the geotechnical engineering report (GER) prepared for the Project Site by the Geotechnical Engineering Group (GEO) of the City of Los Angeles Department of Public Works, Bureau of Engineering (LABOE), in December 2015. This technical report (Geotechnical Engineering Report – Venice Auxiliary Pumping Plant, December 14, 2015) is hereby incorporated by reference and included in Appendix G of this Environmental Impact Report (EIR). Information pertaining to locations of abandoned oil wells is based on the *Phase I Environmental Site Assessment (128 Hurricane Street)* (Phase I ESA) prepared by Ninyo & Moore in May 2016 (see Appendix K of this EIR).

This geotechnical investigation was conducted to provide recommendations for design and construction of the Venice Auxiliary Pumping Plant (VAPP or Proposed Project) at the Project Site. Thus, the recommendations presented in the 2015 GER would be incorporated into project design and construction to address issues related to the following: surficial soils, site preparation, site earthwork, foundations, retaining walls, slabs-on-grade, cement type, and corrosion measures. As recommended in the 2015 GER, a representative of the City's GEO would provide observation and testing services during site earthwork and construction of foundations and review the preliminary foundation and earthwork plans and specifications. For groundwater control and discharge, the representative would review proposals for shoring and jet grouting. In addition, to address the on-site abandoned oil well located at 128 Hurricane Street, soil and soil vapor subsurface investigations and confirmation of oil well abandonment would be required. As noted in the analysis below, with adherence with standard construction requirements and the implementation of mitigation measures, direct and indirect impacts associated with geology and soils during construction or operation would be less than significant.

3.5.1 Regulatory Setting

This section describes existing regulations related to geology and soils that are applicable to the Proposed Project and discusses those can be used to determine impacts and consistency with applicable requirements.

3.5.1.1 California Building Standards Code

The California Building Standards Commission is responsible for coordinating, managing, adopting, and approving building codes in California. In January 2014, the 2013 California Building Standards Code (CBSC) went into effect, updating all prior codes under California Code of Regulations (CCR) Title 24. Among the components of the CBSC are the California Building Code (CBC), Building Standards Administrative Code, Residential Building Code, and Green Buildings Standards Code.

The CBC, which has been incorporated by reference into the City of Los Angeles Municipal Code, applies to building design and construction and is based on the federal Uniform Building Code

(UBC), which is used widely throughout the country. The CBC has been modified for conditions in California. It contains numerous provisions that are more stringent than those in the UBC because of California's seismic and environmental conditions. According to Section 1.1 of the CBC, the provisions of the CBC apply to "the construction, alteration, movement, enlargement, replacement, repair, equipment, use and occupancy, location, maintenance, removal, and demolition of every building or structure or any appurtenances connected or attached to such buildings or structures throughout the State of California," except when modified by local ordinance.

3.5.1.2 Seismic Hazards Mapping Act

The Seismic Hazards Mapping Act, passed in 1990, addresses earthquake hazards from nonsurface fault rupture, including hazards related to liquefaction and seismically induced landslides. The purpose of the Seismic Hazards Mapping Act, which went into effect in 1991, is to identify and map seismic hazard zones. Such mapping helps cities and counties when preparing the safety elements of their general plans and encourages land use management policies and regulations that reduce seismic hazards. The Seismic Hazards Mapping Act has resulted in the publication of maps that delineate Liquefaction Zones and Earthquake-Induced Landslide Zones of Required Investigation (State of California Department of Conservation, California Geological Survey 2011). The Project Site is located within a Liquefaction Seismic Hazard Zone but not within a Landslide Seismic Hazard Zone.

3.5.2 Environmental Setting

This section describes the environmental setting or conditions related to geology, soils, and seismicity as well as associated hazards that could affect the Project Site, workers, visitors, or public. The information in this section is used in preparing the evaluation and conclusions of the impact analysis as well as determining the required mitigation measures.

3.5.2.1 Regional Geology

The VAPP site is located within the Los Angeles Basin part of the Peninsular Ranges geomorphic province, which extends from Southern California to the southern tip of Baja California. This province is characterized by elongated northwest-trending mountain ridges separated by straight-sided sediment-filled valleys. The northwest trend is further displayed in the dominant structural features of the province, including the Newport-Inglewood fault zone.

The Project Site is located in an alluviated lowland area in the west portion of the Los Angeles Basin, a northwest-trending alluviated plain about 50 miles long and 20 miles wide. The basin is bound on the north by the Santa Monica Mountains and the Elysian, Repetto, and Puente Hills and on the east and southeast by the Santa Ana Mountains and San Joaquin Hills. This aerially extensive alluviated plain slopes southward and seaward; however, in the vicinity of the Project Site, the plain is interrupted by the Baldwin Hills and Beverly Hills. The Baldwin Hills are the northern extension of the Newport-Inglewood structural block, which has uplifted the Baldwin Hills, Dominquez Hills, and Signal Hill, located to the south.

The Los Angeles Basin is underlain by a deep structural depression. Parts of this depression have been filled with sediments discontinuously since the Late Cretaceous (starting about 85 million years ago). Starting in the middle Miocene (about 20 million years ago), the basin, which extended to the Ventura Basin, continuously subsided as sediments were deposited. The buried basement surface has relief of as much as 4.5 miles over a distance of 8 miles (Yerkes et al. 1965).

3.5.2.2 Local Geologic Setting

The Marina Del Rey and Venice areas were once a large wetland marsh that was fed by the meandering Ballona Creek, which drained into the Santa Monica Bay near the current location. The 1924 U.S. Geological Survey (USGS) map of the Venice quadrangle shows the Project Site adjacent to a large lowland marsh area northeast of the Grand Canal. The elevation of the Project Site is approximately 5 feet above sea level. Surficial geologic exposures are all Quaternary sedimentary units.

3.5.2.3 Stratigraphy

Artificial fill soils exist within the Project Site as the result of previous construction on the site. In general, the depth of fill is expected to be on the order of 3 to 4 feet within the Project Site. The fill materials generally consist of silty sand and sand with some construction debris.

More detailed descriptions of the soils can be found in the boring logs presented in Appendix G of this Draft EIR.

3.5.2.4 Faulting and Seismicity

The Project Site lies within Seismic Zone 4 (highest potential for seismic activity) of the 2010 CBC. Primary seismic hazards that could affect the site include ground motion or shaking, ground surface rupture along faults, liquefaction, and earthquake-induced landslides.

3.5.2.5 Oil Fields and Methane

According to the State of California, Department of Conservation, Division of Oil, Gas, and Geothermal Resources (DOGGR), Well Finder website (DOGGR, 2016), the site lies within the administrative boundaries of the Playa Del Rey Oil Field. One oil well, the 'McDonald 2' was observed on site, with American Petroleum Institute (API) number 03713842. The well is plugged and abandoned originally in 1932. As described in the Phase I ESA (see Appendix K of this EIR), the well may have been re-abandoned in 2002 to current DOGGR standards, but it is not known whether re-abandonment activities were completed. Numerous oil wells, most of which are plugged and abandoned, were observed within one mile of the site. The presence of a historical oil well on site represents a REC (recognized environmental condition). In addition to being within the boundaries of the Playa Del Rey Oil Field, according to the City of Los Angeles Zoning Information and Map Access System (ZIMAS); the project site also lies within a methane zone. This was also identified as a REC in the Phase I ESA.

3.5.2.6 Ground Motion

Given the current understanding of the geologic framework of the area, the seismic hazard that is expected to have the highest probability of affecting the site is ground shaking or motion resulting from an earthquake occurring along any of several major active or potentially active faults in

Southern California. Known regional faults that could produce significant ground shaking at the site include the Malibu Coast, Santa Monica, Palos Verdes, and Newport-Inglewood faults, among others and are shown in Figure 3.5-1. According to the City of Los Angeles' ZIMAS, the closest fault to the Project Site is the Santa Monica Fault, which is approximately 6.7 miles away.

Ground motion parameters were determined for the site using the USGS 2008 Probabilistic Seismic Hazard Analysis Interactive Deaggregation web tool. Program input included site longitude and latitude, a 10% probability of exceedance in 50 years, and an average shear wave velocity of 230 meters per second for the upper 100 feet of subsurface. Using these parameters, a peak ground acceleration of 0.4g (acceleration of gravity) was determined for the site. The program also calculated a mean earthquake magnitude of 6.7 at a distance of 20.5 kilometers (12.7 miles) from the site.

3.5.2.7 Other Seismic Hazards

Lateral Spreading

Seismically induced lateral spreading is the lateral movement of earth materials due to ground shaking. It differs from slope failure in that complete ground failure from a large earth movement does not occur because of the relatively low gradient of the ground surface. Lateral spreading is demonstrated by near-vertical cracks and predominantly horizontal movement of the soil mass. The GER prepared for the Proposed Project did not identify lateral spreading as an issue of concern for the Project Site.

Liquefaction

According to the State of California Seismic Hazard Zones Map, the Site is located within an area that has potential for liquefaction. Liquefaction is a process that occurs when saturated sediments are subjected to repeated strain reversals during a seismic event. The strain reversals cause an increase in pore water pressure such that the internal pore pressure approaches the overburden pressure, and the shear strength approaches a low residual value. Liquefied soils are subject to flow, consolidation, or excessive strain. Liquefaction typically occurs in loose to medium-dense sand and silty sand soils below the groundwater table. Predominately fine-grained soils, such as silts and clays, are less susceptible to liquefaction.

Liquefaction analyses were performed for a ground acceleration of 0.43g (two-thirds the maximum considered earthquake-geometric mean ground acceleration of 0.642g). The analyses were performed for the deepest rotary wash boring, RW-2 (see Appendix G of this EIR), located near the center of the site, and with consideration of soil particle size and plasticity information obtained through laboratory testing as well as the measured and anticipated high groundwater levels. Potential liquefaction-induced settlements on the order of 2 inches were calculated for the Project Site and 1 inch between the proposed structures and the pipe header (associated with the diversion structure).

3.5.2.8 Other Hazards

An on-site geotechnical investigation conducted in 2006 identified petroleum hydrocarbons in the soil adjacent to two on-site concrete vaults. Petroleum hydrocarbon analytical results in the upper 2 feet of soil resulted in concentrations of up to 6,500 parts per million. The purpose of the concrete vaults is unknown. Furthermore, there was no documentation summarizing the removal of the vaults and/or contaminated soil.

Scale
One Inch = 16 Miles

Figure 3.5-1
Peak Acceleration From Maximum Credible Earthquake
Venice Auxiliary Pumping Plant Project

As part of the Phase I ESA, Ninyo & Moore conducted a preliminary vapor encroachment screening (pVES) to identify potential chemicals of concern (COCs) that could migrate (as vapors) onto the project site as a result of contaminated soil and/or groundwater in nearby properties. The potential for Vapor Encroachment Conditions (VEC) beneath the project site was evaluated and based on the concentration of petroleum hydrocarbons detected in soil on the site in 2006, the presence of a historical oil production well and the presence of the site within a methane zone. The Phase I ESA determined that a VEC likely exists beneath the site.

3.5.3 Environmental Impact Analysis

3.5.3.1 Methodology

Potential significant impacts associated with the Proposed Project were identified from the GER prepared by LABOE in December 2015 and the Phase I ESA prepared by Ninyo & Moore in May 2016. The GER and ESA Phase I presented findings, conclusions, and recommendations concerning development of the Project Site that were based on an engineering analysis of the geotechnical properties of the subsurface conditions (described above).

The discussion below identifies potential project impacts and the measures that would be required to mitigate impacts that are found to be potentially significant.

3.5.3.2 Screening Analysis

As noted in Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and the corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.5.3.3 Thresholds of Significance

In accordance with Appendix G of the State CEQA Guidelines, a project would normally have a significant impact related to geology and soils if it would:

GEO-1. Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

- Strong seismic ground shaking;
- Seismically related ground failure, including liquefaction;

GEO-2. Be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project and potentially result in an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse; or

GEO-3. Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property.

Additionally, due to environmental concerns described in sections 3.5.2.5 and 3.5.2.8 in the project area, in accordance with Appendix G of the State CEQA Guidelines, a project would normally have a significant impact related to hazards and hazardous materials if it would:

HAZ-1. Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous chemicals into the environment.

3.5.3.4 Construction Impacts

During construction of the proposed Project, construction workers, equipment, and structures that are under construction could be exposed to the geologic and soils hazards described below.

GEO-1. Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking and/or seismically related ground failure, including liquefaction.

Although the Project Site is not located on or near a known active fault (see Figure 3-5.1), it could be subject to significant seismic ground shaking from regional faults and therefore, impacts are considered potentially significant related to strong ground shaking hazard. However, the VAPP would be designed by California-licensed professional civil and structural engineers, and construction work would be performed by licensed professional contractors who would comply with all required safety standards to reduce the risk of seismic hazards during construction. The Proposed Project would also be required to conform to the City of Los Angeles Building Code, which considers seismic risk associated with building construction and design requirements. Therefore, the Proposed Project would not expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking and as such, **impacts are considered less than significant and no mitigation measures are required.**

The analysis of the Project Site in the GER indicates that the primary geotechnical issue of concern is related to the uncertified fill soils and the potential for liquefaction. Impacts related to seismically related ground failure, including liquefaction, at the Project Site are therefore considered potentially significant. Potential liquefaction-induced settlement would be on the order of up to 2 inches for the Project Site and 1 inch between the proposed structures and the pipe header. In addition, the Project Site is located in an area identified as having fill material, generally consisting of silty sand and sand with some construction debris, which could expand when saturated. However, the Proposed Project design and construction would incorporate the geotechnical engineering recommendations prescribed in the 2015 GER that assessed the potential for liquefaction at the Project Site and developed recommendations to address this issue. The recommendations focus on surficial soils, site preparation, site earthwork, foundations, retaining walls, slabs-on-grade, cement type, and corrosion measures. **In particular, Mitigation Measure MM-GEO-1 (supporting project structures on concrete mat foundations) would reduce these impacts to less than significant.**

Further, a representative of the City's GEO would review plans and specifications to ensure the proper interpretation and application of these recommendations prior to start of construction and provide observation and testing services to determine if any supplemental recommendations are warranted. Thus, all grading, excavation, and foundation construction would be performed under the observation and testing of the geotechnical engineer or representative of the GEO, as outlined in the 2015 GER. Designs and plans would also be reviewed, per local, state, and federal laws. **Given these measures and the application of Mitigation Measure MM-GEO-1, all impacts associated with seismically related ground failure, including failure related to liquefaction, would be less than significant with mitigation.**

GEO-2. Be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project and potentially result in an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse.

Please see the discussion of seismically related impacts and the conclusions above associated with liquefaction. As noted in that analysis, **impacts were determined to be less than significant with Mitigation Measure MM-GEO-1**. In addition, the Initial Study (see Appendix A) and the GER (see Appendix G) determined that the Project Site is not within a zone of earthquake-induced landslide potential, as shown by the State of California Seismic Hazard Zones Map, nor is it located on a slope. The GER also did not identify lateral spreading, subsidence, or collapse as issues of concern. Therefore, geologic and seismic hazards (excepting liquefaction) identified for the Project Site are less than significant related to an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse. As such, impacts would be **less than significant, and no mitigation measures are required.**

GEO-3. Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property.

As noted above, the GER indicated that the Project Site is located in an area that has been identified as having fill material, generally consisting of silty sand and sand with some construction debris, which could expand when saturated. It did not, however, identify on-site soils as any of those identified in Table 18-1-B of the UBC. Impacts related to expansive soils were previously addressed above in the analysis regarding the potential for liquefaction. As noted in that analysis, the geologic and seismic hazards identified for the Project Site would be reduced by employing required standard engineering practices, including CBC standards, as well as the geotechnical engineering recommendations in the design and construction of the Proposed Project. Adherence to those provisions and standards would reduce risks related to creating substantial risks to life or property due to the presence of expansive soils, including those identified in Table 18-1-B of the UBC (1994). Therefore, potential impacts would be **less than significant, and no mitigation measures are required.**

HAZ-1. Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous chemicals into the environment.

As previously stated, the 128 Hurricane Street site lies within the administrative boundaries of the Playa Del Rey Oil Field. One oil well 'McDonald 2' was observed on site, with American Petroleum Institute (API) number 03713842. The well was originally plugged and abandoned in 1932. However, as mentioned above, the well may have been re-abandoned in 2002, but it is not known whether re-abandonment activities were completed. Numerous oil wells, most of which are plugged and abandoned, were observed within one mile of the site. In addition to being within the boundaries of an oil field, the site also lies within a methane zone (according to the City of Los Angeles ZIMAS website). As such, the project would have the potential to result in impacts associated with releases of methane or oil from the abandoned oil well during excavation activities. **Mitigation Measure MM-HAZ-1** would reduce potentially significant impacts to less than significant.

Additionally, an on-site geotechnical investigation conducted in 2006 identified petroleum hydrocarbons in the soil adjacent to two concrete vaults. There was no documentation summarizing

the removal of the vaults and contaminated soil, thus there is potential for exposure to contaminated soil during construction activities. **Mitigation Measure MM-HAZ-1** would reduce potentially significant impacts to less than significant.

Lastly, the potential for VEC beneath the project site was evaluated. Based on the concentration of petroleum hydrocarbons detected in soil on the site in 2006, the presence of a historical oil production well and the presence of the site within a methane zone, the Phase I ESA determined that a VEC likely exists beneath the site and which is considered a potentially significant impact. **Mitigation Measure MM-HAZ-1** would reduce potentially significant impacts to less than significant.

3.5.3.5 Operational Impacts

Once the VAPP is completed and operational, LABOE personnel, visitors, and structures on the site could be exposed to the geologic and soils hazards, as described below.

GEO-1. Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking and/or seismically related ground failure, including liquefaction.

As noted previously, the Project Site is located within Southern California, a seismically active region that is capable of generating earthquakes (including ground shaking) of considerable magnitude. Although the proposed Project is not located near an active fault (see Figure 3.5-1), movement along active regional faults could generate an earthquake that would be capable of causing damage to buildings and infrastructure located on site and therefore, impacts are potentially significant. The Project Site could also experience liquefaction, including up to 2 inches for structures and up to 1 inch associated with the pipe header, and these impacts are also considered potentially significant. However, the City of Los Angeles Building Code and CBC requires that structures built in the City and state, respectively, be constructed to address the seismic nature of their areas. In addition, the GER has evaluated and considered these factors in the construction and operation of the proposed Project and has identified standard engineering measures and recommendations to address these known regional and localized conditions. As identified within the GER, project implementation does have the potential to result in significant geologic and seismic hazard impacts, including seismically-induced liquefaction. The geologic and seismic hazards identified for the Project Site for employees and visitors would therefore be potentially significant. These can be reduced to less than significant levels, however, through adherence to the City of Los Angeles Building Code and CBC requirements and the implementation of **Mitigation Measure MM-GEO-1**. As such, adherence to these standards and measure would reduce the risks posed by potential hazards from strong seismic ground shaking and/or seismically related ground failure, including failure related to liquefaction, to an acceptable level. Therefore, impacts would be **less than significant and no additional mitigation measures beyond Mitigation Measure MM-GEO-1 are required**.

GEO-2. Be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project and potentially result in an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse.

Please see the discussion of seismically related impacts and the conclusions above associated with liquefaction. As noted in that analysis, impacts were determined to be less than significant with **Mitigation Measure MM-GEO-1**. In addition, the Initial Study (see Appendix A of this EIR) and the

GER (see Appendix G of this EIR) determined that the Project Site is not within a zone of earthquake-induced landslide potential, as shown by the State of California Seismic Hazard Zones Map, nor is it located on a slope. The GER also did not identify lateral spreading, subsidence, or collapse as issues of concern. Therefore, geologic and seismic hazards (excepting liquefaction) identified for the Project Site are less than significant related to an on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse. Therefore, potential impacts would be **less than significant, and no mitigation measures are required.**

GEO-3. Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property.

Please see the discussion of expansive soil–related impacts and conclusions above for construction. As noted in that analysis, the GER indicated that the site is located in an area that has been identified as having fill material, generally consisting of silty sand and sand with some construction debris, which could expand when saturated, potentially resulting in significant impacts. It did not, however, identify the on-site soils as any of those identified in Table 18-1-B of the UBC. Moreover, the analysis related to expansive soils (i.e., related to liquefaction) determined that the geologic and seismic hazards identified for the project study area would be reduced by employing required standard engineering practices, including CBC standards, as well as the geotechnical engineering recommendations in the design and construction of the proposed Project. Adherence to those provisions and standards would reduce risks related to creating substantial risks to life or property due to the presence of expansive soils, including those identified in Table 18-1-B of the UBC (1994). Therefore, potential impacts would be **less than significant and no mitigation measures are required.**

HAZ-1. Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous chemicals into the environment

As mentioned, the proposed project is located within a City of Los Angeles ZIMAS methane zone. As such, long term operations of the proposed project could encounter potential impacts related to the encroachment/seepage of methane into the VAPP structure and as such, impacts are considered potentially significant. However, implementation of **Mitigation Measure MM-HAZ-2** would reduce potential impacts to less than significant.

3.5.4 Mitigation Measures

The following mitigation measure was developed to avoid or minimize potential impacts on the proposed Project related to geology and soils. It should be noted that there are also specific recommendations contained in the *Geotechnical Engineering Report – Venice Auxiliary Pumping Plant*, December 14, 2015 (see Appendix G of this EIR) and *Phase I Environmental Site Assessment (128 Hurricane Street)*, May 2016 (see Appendix K of this EIR).

Mitigation Measure MM-GEO-1 noted below has been abbreviated. The complete text is provided in Appendix G of this EIR.

MM-GEO-1: Liquefaction Considerations

Given the data presented in Section 3 of the *Geotechnical Engineering Report – Venice Auxiliary Pumping Plant*, December 14, 2015, and the results of the liquefaction calculations, potential

liquefaction induced settlements on the order of 1.75 inches are estimated for the site. A potential liquefaction induced differential settlement of 1 inch is estimated between the proposed structures and the pipe header. These potential liquefaction induced settlements shall be considered and accounted for in the design of the Proposed Project.

Mat foundations are recommended for support of the project structures, with the understanding that the foundation would be susceptible to liquefaction-induced settlements. Mat foundations for the wetwell/valve structure and diversion structures shall be founded on jet-grouted columns constructed within the natural soils. The mat foundation for the electrical building shall be founded on compacted fill soil. Mat foundations shall be designed and constructed to bear at a depth of at least 24 inches below the lowest adjacent grade. Mat foundations can be designed for an allowable bearing capacity of 1,500 pounds per square foot (psf). A coefficient of vertical subgrade reaction, for a 1-foot-square loaded area, of 100 kips per cubic foot (kcf) may be used for design of the mats.

Total static settlement of the proposed foundations, designed and constructed in accordance with the recommendations presented herein, shall not exceed 1 inch. Differential static settlement shall not exceed one-half of the total settlement.

Resistance to lateral loads can be provided by friction at the base of the foundation and passive earth pressure. A coefficient of friction of 0.35 may be assumed with dead-load forces. An allowable passive lateral earth pressure of 250 psf per foot of depth up to a maximum of 2,500 psf may be used for sides of the foundation poured against undisturbed natural soil or properly compacted fill. The allowable passive pressure may be increased by 33% of lateral loading due to wind or seismic forces.

MM-HAZ-1a: Soil and Soil Vapor Subsurface Investigation.

Prior to construction, a soil and soil vapor subsurface investigation shall be conducted by a qualified environmental consultant specializing in the identification and handling of hazardous materials. The subsurface investigation may include, but would not be limited to:

- A scope of work consisting of Pre-Field Activities, such as preparation of a Health and Safety Plan (HASP), determining and marking sampling/boring locations and obtaining utility clearance, and Field Activities, such as identifying appropriate sampling procedures, health and safety measures, chemical testing methods, and quality assurance/quality control (QA/QC) procedures in accordance with the ASTM Standard.
- Necessary permits for boring advancement.
- A Sampling and Analysis Plan (SAP) in accordance with the scope of work.
- Laboratory analyses conducted by a State-certified laboratory.
- Disposal process including transport by a State-certified hazardous material hauler to a State-certified disposal or recycling facility licensed to accept and treat hazardous waste.

MM-HAZ-1b: Confirmation of Oil Well Abandonment.

Prior to construction, the applicant shall obtain confirmation via DOGGR of the proper abandonment of oil well 'McDonald 2'. If re-abandonment of McDonald 2 was not performed to current DOGGR requirements, the applicant shall seek the assistance of a qualified environmental consultant to abandon the oil well to current standards.

MM-HAZ-2: Methane Encroachment.

If the analytical results of the subsurface investigation under Mitigation Measure HAZ-1a determine that methane encroachment has the potential to affect VAPP operational activities, the environmental consultant shall provide recommendations during construction of the proposed project to mitigate long term potential impacts.

3.5.5 Significant Unavoidable Adverse Impacts

With implementation of the mitigation measure identified above, no significant and unavoidable adverse impacts related to geology and soils would occur as a result of the Proposed Project.

3.5.6 Cumulative Impacts

The study area for potential cumulative geology and soil impacts consists of the Project Site and the immediate surrounding area, which encompasses the related projects identified in Chapter 2, Project Description. This study area was selected because it encompasses neighborhoods with similar geologic conditions and areas that could be affected by cumulative soil impacts (e.g., cumulative geology, seismically and soil-related impacts).

In general, the proposed Project, in combination with the related projects, would not contribute to significant cumulative geologic impacts because all geologic/seismic impacts would be generally site specific. Project-related impacts deal primarily with hazards at the Project Site that are speculative in nature (e.g., the possibility of an earthquake, liquefaction, landslide). The proposed and related projects would not change the geologic properties of the area. There would continue to be some level of seismic and other geologic risks during operation of the proposed and related projects because of their locations within a seismically active region; however, these risks would not increase or decrease as a result of the proposed and related projects. Additionally, similar to the Proposed Project, the related projects would be subject to applicable seismic standards, safety requirements, and standard design specifications to keep the potential risk of damage from seismic and other geologic hazards to an acceptable level. Therefore, construction and operation of the Proposed and related projects would not result in cumulatively considerable impacts with respect to geology, seismicity, or soils, and no mitigation measures are required.

3.6 Greenhouse Gas Emissions

This section describes the applicable laws and regulations, existing conditions, and impact analysis for greenhouse gas (GHG) emissions. As noted below, construction and operation of the Venice Auxiliary Pumping Plant (VAPP; Proposed Project) would generate both short- and long-term emissions, but these would be less than significant and no mitigation measures are required.

3.6.1 Regulatory Setting

3.6.1.1 Federal

Although federal legislation related to GHG emissions has been introduced and regulations have been promulgated, there is currently no comprehensive policy regarding GHG emissions at the federal level.

Massachusetts et al. v. U.S. Environmental Protection Agency (2007)

Twelve U.S. states and cities, including California, in conjunction with several environmental organizations, sued the U.S. Environmental Protection Agency (EPA) to regulate GHGs as a pollutant, pursuant to the federal Clean Air Act (CAA). The Supreme Court ruled that the plaintiffs had standing to sue, finding that GHGs fit within the CAA's definition of a pollutant, and EPA's reasons for not regulating GHGs were insufficiently grounded.

As a result of the Supreme Court's ruling, on December 7, 2009, the EPA signed the Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202(a) of the CAA.

- Under the Endangerment Finding, the EPA found that the current and projected concentrations of the six key well-mixed GHGs, CO_2, methane (CH_4), nitrous oxide (N_2O), perfluorinated carbons (PFCs), sulfur hexafluoride (SF_6), and hydrofluorocarbons (HFCs), in the atmosphere threaten the public health and welfare of current and future generations.
- Under the Cause or Contribute Findings, EPA found that the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution that threatens public health and welfare.

Although EPA has yet to issue specific regulations regulating GHG emissions, the EPA Administrator's findings were the first step toward future regulations that are currently under development.

EPA Clean Power Plan (2014)

On June 2, 2014, the EPA, under President Obama's Climate Action Plan, proposed a Clean Power Plan, which would be the first to establish national GHG limits for the electric power industry. The proposed rule contains state-specific emission-reduction goals and will help cut carbon pollution from the power sector by 30% from 2005 levels by 2030.

3.6.1.2 State

California has adopted statewide legislation to address issues related to various aspects of climate change and GHG emissions mitigation. Much of this establishes a broad framework for the state's long-term GHG emissions-reduction and climate change adaptation program. The governor of California has also issued several executive orders (EO) related to the state's evolving climate change policy. Of particular importance to local governments is the direction provided by the 2008 California Assembly Bill (AB) 32 Scoping Plan, which recommends that local governments should reduce their GHG emissions to a level consistent with state goals (i.e., 15% below current levels).

In the absence of federal regulations, GHG emissions are generally regulated at the state level and typically approached by setting emissions-reduction targets for existing sources of GHG emissions, establishing policies to promote renewable energy and increase energy efficiency, and developing statewide action plans. Summaries of key policies, legal cases, regulations, and legislation at the state level relevant to the Proposed Project are provided below. Key statewide GHG regulations that are directly applicable to the Proposed Project are also included below.

Assembly Bill 32, the Global Warming Solutions Act of 2006/2011

AB 32 codified the state's GHG emissions target by requiring California's global warming emissions to be reduced to 1990 levels by 2020. Since being adopted, the California Air Resources Board (ARB), the California Energy Commission, the California Public Utilities Commission, and the California Building Standards Commission have been developing regulations that will help the state meet the goals of AB 32 and EO S-03-05. The scoping plan for AB 32 identifies specific measures to reduce GHG emissions to 1990 levels by 2020 and requires ARB and other state agencies to develop and enforce regulations and other initiatives to reduce GHG emissions. Specifically, the scoping plan articulates a key role for local governments by recommending that they establish GHG emissions-reduction goals for both their municipal operations and the community that are consistent with those of the state (i.e., approximately 15 percent below current levels (ARB 2008).

Executive Order S-03-05 (2005)

The goal of EO S-03-05 is to reduce California's GHG emissions to (1) 2000 levels by 2010, (2) 1990 levels by 2020, and (3) 80 percent below 1990 levels by 2050. In 2006, this goal was further reinforced with the passage of AB 32.

Executive Order B-30-15

Signed on April 29, 2015, EO B-30-15 set a goal of reducing GHG emissions to 40 percent below 1990 levels by 2030. The intent is for the state to achieve this interim goal in advance of AB 32's emissions target of 80 percent below 1990 levels by 2050.

California Senate Bill 97

California Senate Bill (SB) 97 required the Governor's Office of Planning and Research (OPR) to develop recommended amendments to the California Environmental Quality Act (CEQA) Guidelines for addressing GHG emissions (OPR 2008). The amendments became effective on March 18, 2010, and included amendments to the CEQA Guidelines addressing the analysis and mitigation of GHG emissions. Those CEQA Guidelines amendments clarified several points, including the following:

- Lead agencies must analyze the greenhouse gas emissions of proposed projects and reach a conclusion regarding the significance of those emissions. (See CEQA Guidelines § 15064.4.)
- When a project's greenhouse gas emissions may be significant, lead agencies must consider a range of potential mitigation measures to reduce those emissions. (See CEQA Guidelines § 15126.4(c).)
- Lead agencies must analyze potentially significant impacts associated with placing projects in hazardous locations, including locations potentially affected by climate change. (See CEQA Guidelines § 15126.2(a).)
- Lead agencies may significantly streamline the analysis of greenhouse gases on a project level by using a programmatic greenhouse gas emissions reduction plan meeting certain criteria. (See CEQA Guidelines § 15183.5(b).)
- CEQA mandates analysis of a proposed project's potential energy use (including transportation-related energy), sources of energy supply, and ways to reduce energy demand, including through the use of efficient transportation alternatives. (See CEQA Guidelines, Appendix F.)

California Senate Bill (SB) 375, Sustainable Communities and Climate Protection Act of 2008

SB 375 requires metropolitan planning organizations (MPOs) to incorporate a "sustainable communities strategy" (SCS) in their regional transportation plans (RTPs) that will achieve the GHG emissions-reduction targets that were set by ARB in February 2011. SB 375 also includes provisions for streamlined CEQA review for some infill projects, such as transit-oriented development. However, those provisions will not become effective until an SCS is adopted. The final targets require the Southern California Association of Governments (SCAG) to identify strategies to reduce per capital GHG emissions from passenger vehicles by approximately 8 percent by 2020, 18 percent by 2035, and 21% by 2040 compared with base-year (i.e., 2005) emissions.

California Green Building Standards Code and Title 24 (2010)

The Green Building Standards Code (CALGreen) applies to the planning, design, operation, construction, use, and occupancy of newly constructed buildings and requires the installation of energy- and water-efficient indoor infrastructure for all new projects beginning after January 1, 2011. CALGreen also requires newly constructed buildings develop a waste management plan and divert at least 50 percent of the construction materials generated during project construction.

Administrative regulations to CALGreen Part 11 and the California Building Energy Efficiency Standards were adopted in 2013 and took effect on January 1, 2014. The 2013 Building Energy Efficiency Standards are 25 percent more efficient than previous standards for residential construction. Part 11 also established voluntary standards that became mandatory in the 2010 edition of the code, including planning and design for sustainable site development, energy efficiency, water conservation, material conservation, and internal air contaminants. The standards offer builders better windows, insulation, lighting, ventilation systems, and other features that reduce energy consumption in homes and businesses.

The next set of energy efficiency standards will be the 2016 Building Energy Efficiency Standards, which are currently going through the rule-making process. These are expected to be adopted in 2016 and take effect on January 1, 2017. According to the California Energy Commission (CEC), single-family homes built to the 2016 standards will use about 28 percent less energy for lighting,

heating, cooling, ventilation, and water heating than those built to the 2013 standards. While the 2016 standards do not require zero net energy (ZNE) buildings, the 2019 standards are expected to take the final step toward achieving ZNE for newly constructed residential buildings throughout California. Later standards are expected to require ZNE for newly constructed commercial buildings.

Cap and Trade (2012)

On October 20, 2011, ARB adopted the final cap-and-trade program for California. The California cap-and-trade program is a market-based system with an overall emissions limit for affected sectors. Examples of affected entities include carbon dioxide suppliers, in-state electricity-generators, hydrogen production, petroleum refining, and other large-scale manufacturers and fuel suppliers. The cap-and-trade program is currently regulating more than 85% of California's emissions. Compliance requirements began according to the following schedule: (1) electricity generation and large industrial sources (2012); (2) fuel combustion and transportation (2015). Cap-and-trade allowance auction proceeds are used to fund a variety of investments. The first 3-year investment plan prioritizes (1) sustainable communities and clean transportation (including low-carbon freight equipment with specific emphasis on efforts that would be beneficial for disadvantaged communities located near ports, railyards, freeways, and distribution centers), (2) energy efficiency and clean energy, and (3) natural resources and waste diversion (ARB 2013a).

California Senate Bill (SB) 350 (2015)

SB 350 (De Leon, also known as the "Clean Energy and Pollution Reduction Act of 2015") was approved in 2015 and includes key provisions to require the following by 2030: (1) a renewable portfolio standard of 50% and (2) a doubling of efficiency for existing buildings.

3.6.1.3 Local

South Coast Air Quality Management District

The South Coast Air Quality Management District (SCAQMD) is responsible for comprehensive air pollution control in the greater Los Angeles area. To provide guidance to local lead agencies on determining significance for GHG emissions in their CEQA documents, the SCAQMD staff is convening an ongoing GHG CEQA Significance Threshold Working Group. Members of the working group include government agencies implementing CEQA and representatives from various stakeholder groups that provide input to the SCAQMD staff on developing GHG CEQA significance thresholds.

On December 5, 2008, the SCAQMD Governing Board adopted the staff proposal for an interim GHG significance threshold for projects where the SCAQMD is lead agency. At present, SCAQMD offers no regulations or thresholds for non-SCAQMD lead agency projects; however, many agencies have used the interim GHG significance threshold identified by SCAQMD in their CEQA documents.

Southern California Associated Governments (SCAG)

Regional Transportation Plan/Sustainable Communities Strategy

SCAG is required by federal law to prepare and update a 20-year long-range Regional Transportation Plan/Sustainable Communities Strategy. Key laws and requirements drive the plan including the Clean Air Act and California Senate Bill 375. Several areas in the SCAG region have

been designated as nonattainment or maintenance areas for one or more transportation-related criteria pollutants. The federal Clean Air Act, requires SCAG's 2016 RTP/SCS to meet all federal transportation conformity requirements, including: regional emissions analysis, financial constraint, timely implementation of transportation control measures, and interagency consultation and public involvement. Additionally, SB 375 requires that the RTP also include a Sustainability Community Strategy, which outlines growth strategies that better integrate land use and transportation planning and help reduce the state's greenhouse gas emissions from cars and light trucks. For the SCAG region, the California Air Resources Board (ARB) has set greenhouse gas reduction targets at eight percent below 2005 per capita emissions levels by 2020, and 13 percent below 2005 per capita emissions levels by 2035.

City of Los Angeles

Green LA: An Action Plan to Lead the Nation in Fighting Global Warming

The City of Los Angeles (City) released its climate action plan, *Green LA: An Action Plan to Lead the Nation in Fighting Global Warming*, in May 2007. The plan sets forth a goal of reducing GHG emissions in the city to 35 percent below 1990 levels by 2030. This voluntary plan identifies more than 50 action items, which are grouped into focus areas, to reduce emissions. The emphasis is on municipal facilities and operations of which the Proposed Project would play a part.

ClimateLA

ClimateLA is an implementation program that provides detailed information about each action item discussed in the Green LA framework (City of Los Angeles 2008). Action items range from harnessing wind power for electricity production to implementing energy-efficient retrofits in City buildings, converting the City's fleet vehicles to cleaner and more-efficient models, and reducing water consumption. Some actions affect only municipal facilities, such as retrofitting City Hall with high-efficiency lighting systems, while others facilitate changes in the private sector (e.g., through rebates for the purchase of energy-efficient appliances). ClimateLA is a living document, reflecting a process of ongoing learning and continuous improvement as technology advances and City departments develop expertise in the methods for lowering GHG emissions.

Sustainable City pLAn, 2015

The Sustainable City pLAn, introduced by Mayor Eric Garcetti in April 2015, identifies goals and strategies for improving Los Angeles' sustainability as it relates to the environment, the economy, and equity. With respect to GHGs, the plan commits to increasing solar power generation and energy efficiency. In addition, it accelerates the City's commitment to attaining GHG reductions, with goals that would reduce GHG emissions levels by 45 percent by 2025, 60 percent by 2035, and 80 percent by 2050 compared with 1990 baseline emissions. The plan also puts forth the goal of improving GHG efficiency[1] by 55 percent by 2025 and 75 percent by 2035 relative to 2009 levels. Other targets identified in the plan include reducing the number of vehicle miles traveled per capita by 5 percent by 2025 and 10 percent by 2035 and increasing the number of trips made by walking, biking, or transit by 35 percent by 2025 and 50 percent by 2035.

[1] GHG efficiency is measured by the amount of GHGs emitted per dollar of economic productivity.

Los Angeles Department of Water and Power: Power Integrated Resource Plan

Released to the public in December 2014, the Power Integrated Resource Plan identifies a portfolio of power generation resources and power system assets to meet the City's future energy needs, with the lowest cost and risk possible, consistent with the Los Angeles Department of Water and Power's (LADWP's) environmental priorities and reliability standards. Updates in the 2014 Power Integrated Resource Plan include new energy efficiency programs to achieve 15 percent energy efficiency savings by 2020, a Demand Response Implementation Plan with a goal to achieve 506 megawatts (MW) of demand response by 2026, and an energy storage procurement target of 178 MW by 2021 to support increased levels of renewable energy. As stated in the 2014 IRP, LADWP has increased the proportion of its electricity coming from renewable sources from 3 percent in 2003 to 23 percent in 2014, and additional increases are forthcoming.

3.6.2 Environmental Setting

A GHG is any gas that absorbs infrared radiation in the atmosphere. This absorption traps heat within the atmosphere, maintaining the earth's surface temperature at a level higher than would be the case in the absence of GHGs. GHGs include water vapor, carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), ozone (O_3), perfluorocarbons (PFCs), hydrofluorocarbons (HFCs), and halogenated chlorofluorocarbons. Naturally occurring GHGs include water vapor, CO_2, CH_4, N_2O, and O_3. Human activities add to the levels of most of these naturally occurring gases. Increasing levels of GHGs in the atmosphere result in an increase in the temperature of the earth's lower atmosphere, a phenomenon that is commonly referred to as "global warming." Warming of the earth's lower atmosphere induces a suite of additional changes, including changes in global precipitation patterns; ocean circulation, temperature, and acidity; global mean sea level; species distribution and diversity; and the timing of biological processes. These large-scale changes are collectively referred to as "global climate change."

The Intergovernmental Panel on Climate Change (IPCC) has been established by the World Meteorological Organization and United Nations Environment Programme to assess scientific, technical, and socioeconomic information relevant to the understanding of climate change and its potential impacts and provide options for adaptation and mitigation. As the leading authority on climate change science, IPCC's best estimates are that average global temperature rise between 2000 and 2100 could range from 0.5°F to 8.6°F (IPCC 2013). Large increases in global temperatures, as high as 8.6°F, could have massive deleterious impacts on natural and human environments. IPCC has concluded that "human influence on the climate system is clear and growing, with impacts observed across all continents and oceans. Many of the observed changes since the 1950s are unprecedented over decades to millennia. The IPCC is now 95 percent certain that humans are the main cause of current global warming" (IPCC 2014: v).

Since the industrial revolution began in approximately 1750, the concentration of CO_2 in the earth's atmosphere has increased from 270 parts per million (ppm) to roughly 391 ppm. Atmospheric concentrations of CH_4 and N_2O have similarly increased since the beginning of the industrial age. Since 1880, the global average surface temperature has increased by 1.5°F, the global average sea level has risen by nearly 190 millimeters (since 1901), and northern hemisphere snow cover (data available since 1920) has decreased by nearly 3 million square kilometers (IPCC 2013). These recently recorded changes can be attributed with a high degree of certainty to increased concentrations of GHGs in the atmosphere. Sinks of CO_2 (which remove rather than emit CO_2) include uptake by vegetation and dissolution into the ocean. Global GHG emissions greatly exceed the removal capacity of natural sinks. As a result, concentrations of GHGs in the atmosphere are increasing (California Energy Commission 2006).

GHGs are global pollutants, unlike criteria air pollutants and toxic air contaminants (TACs). Criteria air pollutants and TACs occur locally or regionally, and local concentrations respond to locally implemented control measures. The long atmospheric lifetimes of GHGs allow them to be transported great distances from sources and become well mixed, unlike criteria air pollutants. Climate change is the cumulative result of GHG emissions and GHG emissions are the cause, on a cumulative basis, of the significant adverse environmental impacts of global climate change.

3.6.2.1 Definition of Greenhouse Gases

The GHGs listed by the IPCC (CO_2, CH_4, N_2O, HFCs, PFCs, and sulphur hexafluoride [SF_6]) (2013) are discussed in this section in order of abundance in the atmosphere. California law and the State CEQA Guidelines contain a similar definition of GHGs (Health and Safety Code Section 38505(g); 14 California Code of Regulations Section 15364.5). Water vapor, the most abundant GHG, is not included in this list because its natural concentrations and fluctuations far outweigh its anthropogenic (human-made) sources.[2] The sources and sinks[3] of each of these gases are discussed in detail below. Generally, GHG emissions are quantified and presented in terms of metric tons of carbon dioxide equivalent (CO_2e) emitted per year. The primary GHGs associated with the project are CO_2, CH_4, and N_2O. HFCs, PFCs, and SF_6 are associated primarily with industrial processes and, thus, are not discussed herein.

To simplify reporting and analysis, GHGs are commonly defined in terms of global warming potential (GWP). The IPCC defines the GWP of various GHG emissions on a normalized scale that recasts all GHG emissions in terms of CO_2e. The GWP of CO_2 is, by definition, 1. The GWP values used in this report are based on IPCC Fourth Assessment Report (AR4) and United Nations Framework Convention on Climate Change (UNFCCC) reporting guidelines and defined in Table 3.6-1, below (IPCC 2007). The AR4 GWP values are used in ARB's California inventory and the most recent AB 32 Scoping Plan estimate update (ARB 2014a).

Table 3.6-1. Lifetime, Global Warming Potential, and Abundance of Several Significant GHGs

Gas	Global Warming Potential (100 years)	Lifetime (years)[a]	Atmospheric Abundance
CO_2 (ppm)	1	50–200	394
CH_4 (ppb)	25	9–15	1,893
N_2O (ppb)	298	121	326

[a] Defined as the half-life of the gas.
ppm = parts per million; ppb = parts per billion
Sources: Myhre et al. 2013; Blasing 2014; ARB 2014a.

[2] Although water vapor plays a substantive role in the natural greenhouse effect, the change in GHGs in the atmosphere due to anthropogenic actions is enough to upset the radiative balance of the atmosphere and result in global warming.
[3] A sink removes and stores GHGs in another form. For example, vegetation is a sink because it removes atmospheric CO_2 during respiration and stores the gas as a chemical compound in its tissues.

CO_2 is the most important anthropogenic GHG. It accounts for more than 75 percent of all GHG emissions emitted by humans. Its atmospheric lifetime of 50 to 200 years ensures that atmospheric concentrations of CO_2 will remain elevated for decades, even after mitigation efforts to reduce GHG concentrations are promulgated (IPCC 2007). The primary sources of anthropogenic CO_2 in the atmosphere include fossil fuel usage (including motor vehicle fuels and coal power plants), gas flaring, cement production, and land use changes (including deforestation).

CH_4, the main component of natural gas, is the second-most abundant GHG and has a GWP of 25 (IPCC 2007). Sources of anthropogenic emissions of CH_4 include growing rice, raising cattle, natural gas combustion, landfill outgassing, and coal mining (National Oceanic and Atmospheric Administration 2005).

N_2O is a powerful GHG, with a GWP of 298 (IPCC 2007). Anthropogenic sources of N_2O include agricultural processes (e.g., fertilizer application), nylon production, fuel-fired power plants, nitric acid production, and vehicle emissions. N_2O is also used in rocket engines and racecars and as an aerosol spray propellant. In the United States, more than 70 percent of N_2O emissions are related to agricultural soil management practices, particularly fertilizer applications.

3.6.2.2 GHG Emissions Sources

More than 97 percent of U.S. GHG emissions result from burning fossil fuels. Although many nations, including the U.S., regularly monitor and report GHG emissions, federal legislation to reduce global emissions has not been adopted, although it is the subject of much debate. EPA is presently pursuing the regulation of GHGs through the federal CAA, following a U.S. Supreme Court ruling that clarified its authority under the CAA to do so. Many states, including California, as a prominent leader, have passed legislation to reduce GHG emissions. California's GHG regulatory framework is discussed in the *Regulatory Setting* section.

Greenhouse Gas Inventories

A GHG inventory is a quantification of all GHG emissions and sinks within a selected physical and/or economic boundary. GHGs can be inventoried on a large scale (i.e., for global and national entities) or a small scale (i.e., for a particular building or person). Although many processes are difficult to evaluate, several agencies have developed tools to quantify emissions from certain sources.

U.S. Greenhouse Gas Emissions Inventory

EPA estimates that total U.S. GHG emissions for 2013 amounted to 6,673 million metric tons (MMT) of CO_2e, which represents a 2.0 percent increase compared with 2012 levels but a 9.0 percent decrease from 2005 levels and a 5.9 percent decrease from 1990 levels. The largest contributors to U.S. GHG emissions in 2013 were electricity generation (31 percent), transportation (27 percent), and the industrial sector (21 percent). Emissions in the electricity generation, transportation, residential, commercial, and industrial sectors consist primarily of CO_2 (82 percent of emissions). GHG emissions from agriculture consist predominantly of CH_4 and N_2O. In general, industrial and, to a lesser extent, commercial emissions in the U.S. have declined over the last decade, while emissions in other sectors, such as transportation, have grown steadily. U.S. GHG emissions are responsible for approximately 16 percent of the global total (EPA 2015).

California Greenhouse Gas Emissions Inventory

In 2013, total California GHG emissions were estimated to be 459.3 $MMTCO_2e$. The transportation sector accounted for approximately 37 percent of total emissions, followed by electricity generation (20 percent), the industrial sector (23 percent), commercial and residential sources (12 percent), agriculture (8 percent), and other sources (6 percent) (ARB 2015).

Annual statewide GHG emissions inventories provide an important tool for establishing historical emission trends and tracking California's progress toward the 2020 goal. From 2000 to 2013, GHG emissions decreased by 2.0 percent. In addition, California's per capita GHG emissions have generally decreased over the last 12 years, going from 14.0 metric tons of CO_2e per person in 2001 to 12.0 in 2013, a 14 percent decrease (ARB 2015).

City of Los Angeles Greenhouse Gas Emissions Inventory

In 2004, total community-wide GHG emissions were greater than 50 $MMTCO_2e$, roughly the same amount as that of Sweden. The transportation sector accounted for approximately 47 percent of total emissions, followed by electricity generation (approximately 32 percent), natural gas use (9 percent), and the burning of other industrial fuels (12 percent) (City of Los Angeles 2008). The City's *Green LA: An Action Plan to Lead the Nation in Fighting Global Warming* includes more than 50 actions for reducing city-wide GHG emissions as well as measures for adapting to the effects of climate change. The City's goal is to reduce GHG emissions to 35 percent below 1990 levels by 2030 (City of Los Angeles 2007).

3.6.2.3 Local Setting

The Bureau of Sanitation is responsible for operating and maintaining one of the world's largest wastewater collection and treatment systems. More than 6,500 miles of sewers serve more than 4 million residential and business customers in Los Angeles as well as 29 contracting cities and agencies. These sewers are connected to the City's four wastewater and water reclamation plants, which process, on average, 550 million gallons per day (mgd). Wastewater treatment operations (processes) are very energy intensive. Such operations, including associated buildings, consume the second-largest amount of electricity among City departments and generate 12.9 percent of all indirect GHG emissions. Wastewater operations, including associated buildings, are ranked fifth among City departments in natural gas usage (City of Los Angeles 2008).

The existing pumps at VPP consume approximately 6.5 million kWh per year.[4] Based on the carbon intensity of LADWP's electricity for 2013, the existing GHG consumption of the existing facility is approximately 3,300 metric tons annually (see Appendix B [Air Quality Emissions and Greenhouse Gas Calculations] of this EIR).

[4] Assumes an annualized 36-mgd wastewater flow.

3.6.3 Environmental Impact Analysis

3.6.3.1 Methodology

Construction

Project construction would be a source of GHG emissions. Such emissions would result from earth moving, the use of heavy equipment, and vehicle use as well as land clearing, ground excavation, and cut-and-fill activities. Construction-period GHG emissions were quantified by using CalEEMod (version 2013.2.2) annual outputs. CalEEMod has been approved by SCAQMD for emissions estimations within the South Coast Air Basin. Consistent with SCAQMD-recommended methodology, total construction-period emissions were amortized over a 30-year period, the assumed life of the Proposed Project, then added to the opening-year GHG emissions total to determine tons per year.

Operation

CalEEMod annual outputs were also used to determine operational GHG emissions. Based on information provided by the project design team (Arcadis), the proposed pumps at VAPP would be more efficient than the existing pumps at VPP. Because the Proposed Project would create redundancy for increased system reliability, the additional pumping capacity would not be needed except during wet-weather events. Assuming an annualized 36-mgd flow for the combined VPP and VAPP facility, there would be little change in overall energy consumption related to pumping. However, there would be an increase in energy consumption related to the operational control room, which would consume approximately 570,000 kWh per year (Arcadis 2016). Additional electricity consumption was assumed based on CalEEMod defaults (see Appendix B of this EIR).

3.6.3.2 Screening Analysis

As noted in Section Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.6.3.3 Thresholds of Significance

State CEQA Guidelines Section 15064.4 provides guidance to lead agencies for determining the significance of impacts from GHG emissions. Section 15064.4(a) states that a lead agency should make a good-faith effort that is based, to the extent possible, on scientific and factual data to describe, calculate, or estimate the amount of GHG emissions that would result from a project. State CEQA Guidelines Section 15064.4(b) also states that, when assessing the significance of impacts from GHG emissions, a lead agency should consider (1) the extent to which the project may increase or reduce GHG emissions compared with existing conditions, (2) whether the project's GHG emissions would exceed a threshold of significance that the lead agency has determined to be applicable to the project, and (3) the extent to which the project would comply with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of GHG emissions.

Because the *L.A. CEQA Thresholds Guide* was adopted prior to the requirement for GHG impacts to be addressed as part of CEQA, there are no local thresholds of significance related to GHGs. Therefore, the thresholds of significance from Appendix G of the State CEQA Guidelines are used, which state that a proposed project would normally have a significant impact on GHG emissions if it were to:

GHG-1. Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment;

GHG-2. Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs.

The State CEQA Guidelines also state that the significance criteria established by the applicable air quality management district or air pollution control district may be relied upon to make the above determinations.

Although SCAQMD has not adopted quantitative thresholds, its staff has developed interim GHG significance thresholds that are applicable to industrial (stationary-source) projects where SCAQMD is the lead agency. The threshold identified by SCAQMD indicates that a project would normally have significant impacts with respect to GHG emissions if it were to:

GHG-3. Result in more than 10,000 metric tons of CO_2e per year, including construction emissions amortized over 30 years added to operational GHG emissions (SCAQMD 2008).

The Proposed Project uses this threshold in its determination of significance.

The project's GHG emissions were evaluated for consistency with California's AB 32 (the Global Warming Solutions Act of 2006) emissions reduction goals, as well as other applicable local plans for reducing GHGs.

Note that GHGs are exclusively cumulative impacts. Therefore, in accordance with the scientific consensus regarding the cumulative nature of GHGs, the analysis herein analyzes the cumulative contribution of project-related GHG emissions.

3.6.3.4 Construction and Operational Impacts

GHG-1. Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment.

Construction of the Proposed Project would result in GHG emissions from fuel combustion associated with heavy-duty construction equipment, construction workers' vehicle trips, material deliveries, and trips by haul trucks. In addition, earthwork would require fuel combustion, resulting in further GHG emissions. As shown in Table 3.6-2, these activities would emit approximately 691 metric tons of CO_2e. Consistent with SCAQMD-prescribed methodology, emissions were amortized over a 30-year period, resulting in 23 metric tons of CO_2e per year.

Table 3.6-2. Project-Related GHG Emissions

Phase	CO_2e (metric tons)
Construction	
Total Construction	691
Amortized Construction	23
Operation	
Annual Operation	382
Energy	336
Mobile	21
Waste	6
Water	19
TOTAL[a]	405
SCAQMD Threshold	10,000

[a] The total includes amortized construction emissions.
Source: CalEEMod modeling by ICF, 2016 (Appendix B of this EIR).

Operation of the Proposed Project would result in GHG emissions from direct energy consumption at the operational building, employee vehicle trips, and waste and potable water distribution. As shown in Table 3.6-2, with the amortized construction-period emissions, project implementation would result in annual emissions of approximately 405 metric tons CO_2e. Table 3.6-2 does not quantify emissions associated with pumping at the future facility, as wastewater flows would not be increased as a result of project implementation. The Proposed Project would create additional capacity for use during infrequent wet-weather events (extreme weather flows), but any increases in emissions due to pumping would be offset by the increased efficiency of the VAPP pumps and the decreasing carbon intensity of LADWP's electricity.

As GHG emissions resulting from project implementation would not exceed SCAQMD's 10,000-metric-ton threshold, impacts would be **less than significant**, and no mitigation measures are required.

GHG-2. Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs.

Implementation of the Proposed Project would generate GHG emissions that would be greater than existing conditions, but would not exceed the interim SCAQMD threshold, as shown in Table 3.6-2. Therefore, the Proposed Project would not directly contribute to the GHG reductions envisioned under AB 32, SB 375, Green LA, ClimateLA, or the Sustainable City pLAn, but would not conflict with state and local GHG reduction goals. Although the project type is not explicitly discussed in any of the GHG reduction plans identified above, Action E12 within ClimateLA aims to "maximize the energy efficiency of wastewater treatment equipment" (City of Los Angeles 2008). Energy efficiency has been incorporated into the project design through the use of variable frequency drives for the pumps, which adjust motor speeds to vary discharge flows, thereby allowing for efficient pump operation. Also, the new pumps would be more energy-efficient than the existing VPP pumps. Thus, the Proposed Project would be consistent with Action E12.

The City has several plans in place addressing GHG emissions reductions (ClimateLA, Green LA, and the Sustainable City pLAn), but the reduction targets are not legally binding. Therefore, the most applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions is AB 32, which codified the state's GHG emissions-reduction targets for 2020. Beyond 2020, there are no adopted enforceable plans, policies, or regulations pursuant to EO S-03-05 and EO B-30-15 that are legally applicable to the project. Regardless, an overview of proposed plans and discussion documents designed to help meet EO S-03-05 and EO B-30-15 targets is provided.

AB 32 Scoping Plan

AB 32 identified 427 $MMTCO_2e$ as the acceptable level of GHG emissions for California in 2020, which is the same as the 1990 GHG emissions level and approximately 28.5% less than 2020 business-as-usual (BAU) conditions (596 $MMTCO_2e$).[5] To reach the target level, there will have to be widespread reductions in GHG emissions across California. Some reductions will need to come in the form of changes pertaining to vehicle emissions and mileage standards. Some will come from changes pertaining to sources of electricity and increased energy efficiency at existing facilities. The remainder will need to come from plans, policies, or regulations that will require new facilities to have lower carbon intensities than they have under BAU conditions.

The AB 32 Scoping Plan details specific GHG emissions-reduction measures that target specific GHG emissions sources. The scoping plan considers a range of actions, including direct regulations, alternative compliance mechanisms, monetary and non-monetary incentives, voluntary actions, and market-based mechanisms (e.g., a cap-and-trade system). Also included are mobile-source emissions reduction measures (Pavley, Low-Carbon Fuel Standard [LCFS], vehicle efficiency measures), energy production–related emissions-reduction measures (natural gas transmission and distribution efficiency measures, natural gas extraction efficiency measures), and the renewable portfolio standard (electricity). The Proposed Project would be consistent with the measures identified in Table 3.6-3 contained within the AB 32 Scoping Plan and other measures adopted by ARB but not yet included in the scoping plan. A demonstration of the consistency with key ARB measures is included in Table 3.6-3. As a result, Proposed Project-related GHG emissions would be reduced through several of the AB 32 Scoping Plan measures. Accordingly, the Proposed Project would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs, and as such, **impacts would be less than significant**, and no mitigation measures are required.

[5] ARB recently updated the AB 32 Scoping Plan and revised the 2020 BAU downward slightly to 509 $MMTCO_2e$, which reflects the reduced GHG emissions estimates resulting from the recent economic downturn and increased efficiencies.

Table 3.6-3. Project Consistency with AB 32 Scoping Plan and Other ARB Measures

No.	Measure Description	Project Consistency
Scoping Plan Measures		
T-1	Advanced Clean Cars	**No conflict**. State program that requires no action at the local or project level. Benefits to project-related employee vehicle travel will be realized.
T-2	Low Carbon Fuel Standard	**No conflict**. State program that requires no action at the local or project level. Benefits to project-related vehicle travel will be realized.
T-3	Regional Transportation-Related Greenhouse Gas Targets	**No conflict**. State program that requires no action at the project level. SCAG is responsible for implementing the SCS and is currently revising the SCS as part of the 2016 RTP/SCS. Benefits to project-related employee vehicle travel will be realized.
T-4	Vehicle Efficiency Measures 1. Tire Pressure 2. Fuel Efficiency Tire Program 3. Low Friction Oil 4. Solar Reflective Automotive Paint and Window Glazing	**No conflict**. State program that requires no action at the local or project level. Benefits to project-related car and truck travel will be realized.
T-7	Heavy-Duty Vehicle GHG Emission Reduction 1. Tractor-Trailer GHG Regulation 2. Heavy Duty Greenhouse Gas Standards for New Vehicle and Engines (Phase I)	**No conflict**. State and federal programs that require no action at the local or project level. Benefits to project-related truck travel will be realized.
E-1	1. Building Energy Efficiency – Electricity 2.Appliance Energy Efficiency Standards – Electricity	**No conflict**. State program that requires no action at the local or project level. Proposed Project includes building efficiency design that will reduce emissions from electricity consumption.
CR-1	1. Building Energy Efficiency – Natural Gas 2.Appliance Energy Efficiency Standards – Natural Gas	**No conflict**. State program that requires no action at the local or project level. Proposed Project includes building efficiency design that will reduce emissions from natural gas consumption.
E-3	33 Percent Renewable Portfolio Standard	**No conflict**. State program that requires no action at the local or project level. Benefits to project-related electricity and water consumption will be realized.
W-1	Water Use Efficiency	**No conflict**. The Proposed Project proposes water fixture and irrigation efficiency measures to reduce water use. Moreover, this is a state program that requires no action at the local or project level. Benefits will be realized at the project level.
H-5	1. Low Global Warming Potential Refrigerants for New Motor Vehicle Air-Conditioning Systems	**No conflict**. State program that requires no action at the local or project level. Benefits will be realized independently.

No.	Measure Description	Project Consistency
Other ARB Measures		
-	Renewable Portfolio Standard (50% by 2030) per SB 350	**No conflict**. See E-3. State program that requires no action at the local or project level. Benefits to project-related electricity and water consumption will be realized.
-	Pavley (AB 1493)	**No conflict**. See T-1 and T-2. State program that requires no action at the local or project level. Benefits to project-related employee car travel will be realized.
-	Heavy Duty (Tractor-Trailer) GHG Regulation	**No conflict**. See T-7. State and federal programs that require no action at the local or project level. Benefits to project-related truck travel will be realized.

T = Transportation Measures; E = Electricity Measures; W = Water Measures; H = High GWP Measures

Green LA, ClimateLA, and Sustainability pLAn

The City's Green LA Climate Action Plan (CAP) created a concrete set of objectives and actions designed to make Los Angeles a leader in confronting global climate change and reducing GHG emissions. The Green LA CAP identifies over 50 individual action items that will lead Los Angeles to lower GHG emission levels. The City's ClimateLA is the implementation program for the Green LA Plan, and describes each of these action items, providing a context, lead departments, a timeline for completion of each measure, and GHG reduction potential from each action item. These action items and measures aim to reduce emissions directly from municipal facilities and operations and create a framework to address citywide GHG emissions. The actions build on the City's leadership in developing and implementing sustainable environmental policy. The major focus areas include energy, water transportation, land use, waste, Port, airport, open space and greening, green economy, and adaptation. The Sustainable City pLAn builds on ClimateLA and Green LA, and accelerates the City's commitment to reducing GHG emissions. A summary of project consistency with major goals and action items included in Green LA, ClimateLA, and the Sustainable City pLAn is provided in Table 3.6-4. As shown below, the project would not conflict with major goals and action items within the City's Green LA CAP, ClimateLA implementation plan, or Sustainable City pLAn. Accordingly, the Proposed Project would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs, and as such, **impacts would be less than significant and no mitigation measures are required.**

Table 3.6-4. Project Consistency with Green LA and ClimateLA, and Sustainable City pLAn Goals, Actions, and Targets

No.	Goal or Action Description	Project Consistency
Goal	Green the Power From the Largest Municipal Utility in the United States	**No conflict.** Actions include increasing use of renewables to 20% by 2010 and to 35% by 2020. This is a regional action that requires no action at the project level and reductions will be realized over time (similar to statewide RPS).
Goal	Transform Los Angeles Into The Model of an Energy Efficient City	**No conflict.** Actions include reducing energy use by all City departments to the maximum extent feasible and completing energy efficiency retrofits of all City-owned buildings to meet a 20% or more reduction in energy consumption. The Proposed Project would add redundancy and capacity relative to existing conditions, but would involve the use of more energy-efficient pumps.
Action E7	Reduce energy use by all City departments to the maximum extent feasible.	**No conflict.** The Proposed Project would add redundancy and capacity, which would require additional energy use compared with existing conditions. However, the project would not preclude the Department of Public Works from achieving overall reductions in energy use through other projects.
Action E12	Maximize energy efficiency of wastewater treatment equipment.	**No conflict.** Energy efficiency has been incorporated into the project design through the use of variable frequency drives for the pumps, which adjust motor speeds to vary discharge flows, thereby allowing for efficient pump operation. In addition, the new pumps would be more energy-efficient than the existing pumps.
Goal	Decrease Per Capita Water Use	**No conflict**. Actions include meeting all additional demand for water resulting from growth through water conservation and recycling, reducing per capita water consumption by 20%, and implementing the City's innovative water and wastewater integrated resources plan that will increase conservation, and maximize use of recycled water, including capture and reuse of stormwater. The Proposed Project would require minimal amounts of potable water, primarily for cleaning and restroom facilities, and would be in compliance with all standards for water efficiency.
Target	Reduce number of annual sewer spill to fewer than 100 by 2025 and 67 by 2035.	**No conflict.** The Proposed Project would add redundancy and capacity to prevent sanitary sewer overflows.

EO S-03-05 and EO B-30-15

EO B-30-15 established an interim GHG reduction target of 40 percent below 1990 levels by 2030, and EO S-3-05 established a long-term goal of reducing statewide GHG emissions to 80 percent below 1990 levels by 2050. Achieving these long-term GHG reduction policies will require systemic changes in how energy is produced and used.

There a number of studies that discuss potential mechanisms for limiting statewide GHG emissions to meet the aggressive goals identified by EO B-30-15 and EO S-3-05. For example, ARB and other state agencies commissioned Energy + Environmental Economics (E3) in 2015 to develop feasible GHG reduction scenarios for 2030. Other studies include a report by the California Center for Science and Technology (2012), the California Department of Transportation's (2015) *California Transportation Plan 2040,* ARB's *First Update to the AB 32 Scoping Plan*, and a study published in *Science* that analyzes the changes that will be required to reduce GHG emissions to 80 percent below 1990 levels by 2050 (Williams et al. 2012). In general, these studies reach similar conclusions—deep reductions in GHG emissions can *only* be achieved with significant changes in electricity production, transportation fuels, and industrial processes (e.g., decarbonizing electricity production, electrifying transportation, utilizing alternative fuels for aviation).

The systemic changes that will be required to achieve EO B-30-15 and EO S-3-05, if they are legislatively adopted, will require significant policy, technical, and economic solutions. Some changes, such as the use of alternative fuels (e.g., biofuel) to replace petroleum for aviation, cannot be accomplished without action by the federal government. Similarly, achieving the reduction goals will require California to dramatically increase the amount of electricity that is generated by renewable generation sources and, correspondingly, advance the deployment of energy storage technology and smart-grid strategies, such as price-responsive demand and the smart charging of vehicles. Although the City has increased its efforts in all of the areas discussed above, most notably for renewable source electricity generation, a significant statewide redesign of California's electricity system is needed to accomplish GHG emissions reduction goals. Accordingly, in evaluating the project's emissions for consistency with EO S-3-05 and EO B-30-15, it is important to note that many of the broad-scale shifts needed to meet the reduction goals are outside of the control of the City and beyond the scope of the Proposed Project.

The long-term climate change policy and regulatory changes that will be enacted to meet 2030 and 2050 emissions reduction targets are unknown at this time. As a consequence, the extent to which the project's emissions and resulting impacts will be mitigated through implementation of statewide (and nationwide) changes is not known. However, some of the anticipated statewide actions (e.g., decarbonization, energy efficiency, alternative transportation) can be facilitated, at least to some extent, through implementation of specific GHG reduction measures in large-scale developments. The Proposed Project includes a variable frequency drive, which would optimize the energy efficiency of the pumps.

The Proposed Project would be constructed and fully operational prior to 2020, but would remain in operation over a long period of years. Project features are consistent with anticipated long-term statewide strategies to reduce GHG emissions and would help to facilitate substantial progress towards long term targets as adopted (SB 350) and proposed (Phase 2 trucks) state regulations are fully realized. Accordingly, the Proposed Project would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs, and as such, **impacts would be less than significant and no mitigation measures are required.**

2016-2040 RTP/SCS and Air Quality Management Plan

SCAG is the regional planning agency for Los Angeles, Orange, Ventura, Riverside, San Bernardino, and Imperial Counties. SCAG addresses regional issues related to transportation, the economy, community development, and the environment. SCAG's 2016-2040 RTP/SCS integrates land use and transportation strategies to meet and exceed required emission reductions per SB 375 of 8% by 2020, and 18% by 2035 and 21% by 2040 compared with the base year (i.e., 2005). The RTP/SCS includes setting forth a development pattern for the region integrates with the transportation network, measures, and policies to reduce GHG emissions from light-duty automobiles and trucks. The RTP/SCS must conform to the federal Clean Air Act.

Most emissions from typical development projects are generated by the transportation sector and the transportation sector is subject to the most robust regulatory program. For example, LCFS, Pavley I, and Pavley II are expected to reduce GHG emissions from passenger vehicles approximately 34 percent by 2020.[6] Emissions from heavy-duty trucks would decrease over time per adopted ("Phase 1") and pending ("Phase 2") GHG-reduction regulations from both the ARB and EPA.[7] Additionally, GHG intensity of buildings would decrease as the state and LADWP move towards the 50% renewable requirement per SB 350. The project proposes a land use that would not generate a substantial number of vehicle trips, and associated mobile source emissions would not conflict with or delay implementation of the SCS/RTP. This **impact is considered less than significant.**

Because sources of GHG emissions are frequently responsible for emitting criteria pollutants as well, an analysis of the project's potential for conflicts the SCAQMD Air Quality Management Plan is discussed below. SCAQMD is required to reduce emissions of criteria pollutants for which the Basin is in nonattainment status and develop reduction attainment plans. SCAQMD's most recent plan to achieve air quality standards is the 2012 AQMP, which outlines a comprehensive control strategy to meet PM2.5 and O_3 standards. Additionally, measures within AB 32 are aimed at GHG-emitting sources that are in most cases the same sources that emit criteria pollutants, including pollutants that contribute to the Basin's nonattainment status. The 2012 AQMP includes an analysis of the air quality co-benefits of AB 32. The SCAQMD relies on various emission reduction control strategies aimed primarily at stationary (permitted), area, and mobile sources. The mobile source strategy includes actions seeking further emission reductions from both on-road and off-road mobile sources, such as accelerated penetration of zero- and near-zero emission vehicles and early retirement of older vehicles. Some of the proposed actions rely on other agencies, including the state, to implement (SCAQMD 2013). As described in the Air Quality section of this EIR, the project would be consistent with the AQMP because it would result in emissions below regional and localized criteria pollutant thresholds to ensure that no violations of the National Ambient Air Quality Standards and California Ambient Air Quality Standards occur locally. Accordingly, the Proposed Project would not delay implementation of the AQMP. Therefore, the Proposed Project would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing emissions of GHGs, and as such, **impacts would be less than significant and no mitigation measures are required.**

[6] Pavley I and II require manufacturers to reduce per-mile GHG emissions starting in 2009. Pavley I required manufacturers to reduce emissions by about 30% by 2016; Pavley II sets a reduction target of 45% by 2020.

[7] Phase 1 and Phase 2 refer to the National Highway Traffic Safety Administration's HD Fuel Efficiency Improvement Program, which requires improvements in fuel efficiency for medium- and heavy-duty on-road vehicles.

3.6.4 Mitigation Measures

No mitigation measures are required.

3.6.5 Significant Unavoidable Adverse Impacts

No significant unavoidable adverse impacts would result from project implementation related to GHGs.

3.6.6 Cumulative Impacts

GHG emissions are exclusively cumulative impacts; there are no non-cumulative GHG emissions impacts from a climate change perspective. No single project, when considered in isolation, can cause climate change because a single project's emissions are not enough to change the radiative balance of the atmosphere. Because climate change is the result of GHG emissions and GHGs are emitted by innumerable sources worldwide, global climate change will have a significant cumulative impact on the natural environment as well as human development and activity. As such, GHGs and climate change are cumulatively considerable, even though the contribution may be individually limited (SCAQMD 2008). SCAQMD methodology and thresholds are thus cumulative in nature. As discussed above, the Proposed Project would not exceed the threshold of significance. Based on the project not exceeding the SCAQMD emissions threshold and the lack of conflict with GHG emissions reductions plans and policies, **the Proposed Project would not result in a cumulatively considerable impact related to GHGs.**

3.7 Hydrology and Water Quality

This section describes the regulatory setting and current conditions of the Project Site related to hydrology, water quality, tsunami, and sea level rise. The environmental setting information and analysis in this section are based on the *Hydrology Technical Memorandum* prepared by Watearth, dated August, 2016. This technical report is hereby incorporated by reference and included as Appendix H of this Draft Environmental Impact Report (EIR).

The *Hydrology Technical Memorandum* was prepared to provide recommendations for design and construction of the Venice Auxiliary Pumping Plant (VAPP or Proposed Project) at the Project Site. Thus, the recommendations presented in that report are incorporated into project design and construction and address on- and off-site hydrology and water quality impacts. As noted in the analysis below, with the implementation of best management practices, most direct and indirect impacts associated with hydrology and water quality during construction or operation of the Proposed Project would be less than significant. However, impacts related to inundation associated with tsunami and sea level rise are significant and unavoidable.

3.7.1 Regulatory Setting

This section provides an overview of the pertinent federal, state, and local policies governing hydrology, water quality, and sea level rise for the Proposed Project.

3.7.1.1 Federal

Clean Water Act

The federal Clean Water Act (CWA) of 1977 (33 U.S. Code Section 1251 et seq.), which amended the federal Water Pollution Control Act of 1972, established the basic structure for regulating discharges of pollutants into the waters of the United States (not including groundwater). The CWA delegates authority to the U.S. Environmental Protection Agency (EPA) to implement pollution control programs. Under the CWA, it is unlawful for any person to discharge any pollutant from a point source into navigable waters, unless a National Pollutant Discharge Elimination System (NPDES) permit is obtained and implemented in compliance. In addition, the CWA requires that states adopt water quality standards (WQS) for water bodies and that those standards be approved by EPA. Water quality standards consist of two components: designated beneficial uses for a particular receiving water body (e.g., wildlife habitat, agricultural supply, fishing), and water quality criteria necessary to support those uses.

Section 303: Impaired Water Bodies (303(d) list) and Total Maximum Daily Loads

Section 303(d) requires each state to identify and list impaired surface waters that do not meet or that the state expects will not meet state water quality standards. In California, the State Water Resources Control Board (SWRCB) and Regional Water Quality Control Boards (RWQCBs) are responsible for assessing water quality monitoring data for surface waters every two years to determine if they contain pollutants exceeding the levels established in water quality standards. For these waters, the RWQCBs are required to develop total maximum daily loads (TMDL) of pollutants for impaired water bodies and a program of implementation to meet the TMDLs. The TMDL must account for the pollution sources causing the water to be listed by the state. The TMDL is a

calculation of the maximum amount of a pollutant that a water body can receive while still meeting water quality standards. TMDLs also define an allocation of that load among the various sources of that pollutant (i.e., municipalities, other permitted entities, etc.). Additionally, the TMDL can act as a plan to reduce pollutant loading, which improves water quality. After implementation of a TMDL, it is anticipated that the problems that led to placement of a given pollutant on the Section 303(d) list would be remediated.

The SWRCB has combined its 303(d) list and the 305(b) report into the 2012 California Integrated Report. After approval of the 303(d) list portion of the California Integrated Report by the SWRCB, the complete California Integrated Report was submitted to the USEPA. The USEPA approved the 303(d) list portion of the California Integrated Report on July 30, 2015.

The SWRCB 303(d)-listed impaired waters that could potentially be affected by the Proposed Project are discussed and evaluated in Table 3.7-1.

Section 401: Water Quality Certification

Section 401 of the CWA requires an applicant for any federal permit that proposes an activity that may result in a discharge to waters of the United States to obtain certification from the state that the discharge will comply with other provisions of the CWA. In California, the authority to either grant water quality certification or waive the requirement is delegated by the SWRCB to the nine RWQCBs. After receiving the certification, applicants are required to meet effluent limitations and monitoring requirements necessary to ensure compliance with the federal license or permit. The 401 certification provides for the protection of the physical, chemical, and biological integrity of waters.

Section 402: National Pollutant Discharge Elimination System Permits

Section 402 of the CWA establishes the NPDES permit program to regulate the discharge of pollutants from point sources (storm drains, ditches, etc.) into waters of the U.S. In general, the NPDES permit program controls, minimizes, or reduces surface water impacts. In California, the SWRCB administers the NPDES program, and the RWQCBs have implementation and enforcement responsibilities. The NPDES program is applicable to all discharges to waters of the U.S., including stormwater associated with construction activities, industrial operations, municipal drainage systems, and point sources to protect surface water quality. CWA Section 402(p) requires that states develop and implement stormwater management programs to meet the requirements for stormwater discharges from construction activities, industrial operations, and municipal separate storm sewer systems (MS4 permit [see below]).

Stormwater discharges in California are commonly regulated through general and individual NPDES permits, which are adopted by the SWRCB or RWQCBs and are administered by the RWQCBs. Two types of the NPDES program stormwater permits would be relevant to the Project Site and are discussed in Section 3.7.1.2, NPDES, the Construction General Permit (discussed below) and MS4 Permit.

Section 404: Permits For Dredged or Fill Material

Under Section 404, the U.S. Army Corps of Engineers (USACE) and the EPA regulate the discharge of dredged and fill materials into the waters of the United States. These waters are primarily defined as navigable waterways or water features (including wetlands) that have a significant nexus to navigable waters. Project sponsors must obtain authorization from USACE for all discharges of dredged or fill materials into waters of the United States before proceeding with a proposed activity.

Individual Section 404 permits may only be issued for a least environmentally damaging practicable alternative. Compliance with CWA Section 404 requires compliance with several other environmental laws and regulations. The USACE cannot issue an individual permit or verify the use of a general permit until the requirements of the National Environmental Policy Act of 1969 (NEPA), Endangered Species Act (ESA), the Coastal Zone Management Act (CZMA), and the National Historic Preservation Act (NHPA) have been met. Additionally, no permit can be issued or verified until a water quality certification, or waiver of certification, has been issued pursuant to CWA Section 401.

Section 10 of Rivers and Harbors Act of 1899

The Rivers and Harbors Act is a primary federal law regulating activities that may affect navigation on the nation's waterways. Section 10 of the Rivers and Harbors Act grants USACE control over obstructions to navigable waters of the U.S. and gives the USACE exclusive authority to approve construction of smaller structures, such as wharves, booms, and bulkheads, as well as to approve dredging and filling operations.

The Proposed Project may require a Section 10 Permit from the USACE for the submerged diversion structure within the Grand Canal.

Federal Executive Order 11988—Floodplain Management

Executive Order 11988 requires federal agencies to recognize the value of floodplains and to consider the public benefits of restoring and preserving floodplains. Under this order, the USACE has the responsibility of reviewing flood protection projects that may affect navigable waters. USACE is required to take action and provide leadership to avoid development in the base floodplain; reduce the risk and hazard associated with floods; minimize the impact of floods on human health, welfare, and safety; and restore and preserve the beneficial and natural values of the base floodplain.

National Flood Insurance Act and Flood Disaster Protection Act

The National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973 were enacted to reduce the need for flood protection structures and to limit disaster relief costs by restricting development in floodplains. One of FEMA's duties is to administer the National Floodplain Insurance Program (NFIP) and to develop standards for fluvial and coastal floodplain delineation. The NFIP is a federal program enabling property owners in participating communities to purchase insurance as protection against flood losses in exchange for state and community floodplain management regulations that reduce future flood damages.

Federal Strategies to Address Sea Level Rise

Global climate change is occurring as evidenced by increasing mean atmospheric temperatures, melting ice caps and glaciers, extreme precipitation and drought cycles, and global sea level rise with a consequent increase in catastrophic events throughout the world. The scientific community has been quantifying the effects of climatic changes at global and local scales, while policymakers have been developing policies and strategies to reduce risks and to include climate change science in the existing regulatory frameworks.

Federal efforts to address sea level rise consists of a number of initiatives directing federal agencies to design plans to adapt to the future effects of climate change (Executive Orders 13514 and 13653) and a number of initiatives that specifically target sea level rise, like the US Army Corps of Engineers

(USACE) directive to include sea level rise when designing, planning, engineering, operating and maintaining projects.

The most recent effort is President Obama's January 2015 Executive Order 13960, which modifies Executive Order 11988, Floodplain Management, and recommends using a new flood standard that accounts for climate change in establishing flood elevation and hazard areas when federal funds are used to build, significantly retrofit, or repair structures.

3.7.1.2 State

Responsibility for the protection of water quality in California resides with the SWRCB and nine RWQCBs. The SWRCB establishes statewide policies and regulations for the implementation of water quality control programs mandated by federal and state water quality statutes and regulations. The RWQCBs develop and implement Basin Plans that consider regional beneficial uses, water quality characteristics, and water quality problems. The VAPP Project Site is within the jurisdiction of the Los Angeles RWQCB. The Los Angeles RWQCB and SWRCB implement a number of federal and state laws regarding water quality, the most important of which are the State of California's Porter-Cologne Water Quality Control Act and the federal CWA.

The Porter-Cologne Water Quality Control Act

The State of California's Porter-Cologne Water Quality Control Act (Division 7 of the California Water Code) provides the basis for water quality regulation within California. It includes the California Toxics Rule (CTR); the Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California (State Implementation Plan, or SIP); Inland Surface Water Quality Standards; the California Urban Water Management Act; and NPDES permits. The SWRCB administers water rights, water pollution control, and water quality functions throughout the state, while the RWQCBs conduct planning, permitting, and enforcement activities. The Porter-Cologne Water Quality Control Act authorizes the SWRCB to adopt, review, and revise policies for all waters of the state (including both surface and groundwater) and directs the RWQCBs to develop regional Basin Plans. Section 13170 of the California Water Code also authorizes the SWRCB to adopt Basin Plans on its own initiative.

The RWQCBs are required, by law, to develop, adopt, and implement a Basin Plan for the entire region. The principal elements of the Basin Plan are a statement of beneficial water uses that the RWQCBs will protect; water quality objectives needed to protect the designated beneficial water uses; and strategies and time schedules for achieving the water quality objectives. The water quality objectives are achieved primarily through the establishment and enforcement of waste discharge requirements (WDRs).

Water quality standards are set forth in the regional Basin Plan. Designated beneficial uses, along with water quality objectives to meet beneficial uses, compose the relevant water quality standards. Water quality objectives are achieved primarily through the establishment and enforcement of WDRs. All dischargers of waste to waters of the state are subject to regulation under the Porter-Cologne Water Quality Control Act. This includes both point- and nonpoint-source dischargers. All current and proposed discharges to land must be regulated under WDRs, waivers of WDRs, a basin plan prohibition, or some combination of these administrative tools. Discharges of waste directly to state waters would be subject to an individual or general NPDES permit, which also serves as a WDR.

The RWQCBs specifically designate beneficial uses for surface and groundwaters; set narrative and numerical objectives that must be attained or maintained to protect the designated beneficial uses and conform to the state's antidegradation policy; and describe implementation programs to protect all waters in the region. In cases where the Basin Plan does not contain a criterion for a particular pollutant, other criteria are used to establish a water quality objective. These may be applied from SWRCB documents (e.g., the Inland Surface Waters Plan, the Pollutant Policy Document) or from water quality criteria developed under Section 304(a) of the CWA, which requires development of criteria for water quality that accurately reflect the latest scientific knowledge (e.g., CTR).

Discharges from artificial conveyances, such as flood control channels and minor lakes that are part of the City's storm drain system, may not have designated beneficial uses or water quality objectives. For those waters that don't have specific beneficial uses or water quality objectives, the tributary rule[1] applies.

National Pollutant Discharge Elimination System

The SWRCB and RWQCBs implement, monitor, and enforce the NPDES permitting requirements within their jurisdictions. In general, the regulations require all communities with populations over 50,000 to develop programs for reducing pollutants carried by stormwater runoff into waters of the United States. The SWRCB and RWQCBs also develop and implement state or regional general permits regulating certain types of discharges, as applicable. These permits serve as the mechanism for enforcement of the program. As with WDRs, the SWRCB and RWQCBs can issue individual NPDES permits to cover individual dischargers, or general permits to cover a category of dischargers. General permits can be issued on a statewide basis by the SWRCB or on a regional basis by the RWQCBs.

Construction General Permit

Pursuant to CWA Section 402(p) and as related to the goals of the Porter-Cologne Water Quality Control Act, the SWRCB has issued a statewide NPDES General Permit for Stormwater Discharges Associated with Construction Activity (Order No. 2009-0009-DWQ, NPDES No. CAS000002, as amended by Order 2010-0014-DWQ and 2012-006-DWQ) (Construction General Permit), adopted September 2, 2009. Every construction project that disturbs one or more acres of land surface or that is part of a common plan of development or sale that disturbs more than one acre of land surface would require coverage under this Construction General Permit. To obtain coverage under this Construction General Permit, the landowner or other applicable entity must file Permit Registration Documents prior to the commencement of construction activity, which include a Notice of Intent (NOI) and Stormwater Pollution Prevention Plan (SWPPP), and mail the appropriate permit fee to the SWRCB.

Because the Project Site is less than one acre, the NPDES Construction General Permit (Order No. 2009-0009-DWQ, NPDES No. CAS000002) does not apply. Therefore, erosion and sediment control BMPs would be implemented in accordance with the MS4 Permit and City of Los Angeles Development Construction Model Program, as described further below.

[1] The "tributary rule" refers to any streams not specifically listed in the Basin Plan that are deemed to have the same beneficial uses and water quality objectives of the listed stream, river, or lake to which they are a tributary.

Municipal General Permit

CWA Section 402 mandates permits for municipal stormwater discharges, which are regulated under the NPDES General Permit for Municipal Separate Storm Sewer Systems (MS4 Permit). Phase I MS4 Permit regulations cover medium (serving between 100,000 and 250,000 people) and large (serving more than 250,000 people) municipalities. Phase II (Small MS4 Permit) regulations require that stormwater management plans/programs be developed by municipalities with populations smaller than 100,000, including non-traditional Small MS4s, which are facilities such as military bases, public campuses, and prison and hospital complexes.

MS4 Permits require that cities and counties develop and implement programs and measures, including BMPs, control techniques, system design and engineering methods, and other measures as appropriate, to reduce the discharge of pollutants in stormwater to the maximum extent possible. As part of permit compliance, these permit holders have created stormwater management plans for their respective locations. These plans outline the requirements for municipal operations, industrial and commercial businesses, construction sites, and planning and land development. These requirements may include multiple measures to control pollutants in stormwater discharge. During implementation of specific projects under the program, project applicants are required to follow the guidance contained in the stormwater management plans as defined by the permit holder in that location.

The SWRCB is advancing Low-Impact Development (LID) in California as a means of complying with municipal stormwater permits. LID incorporates site design, including among other things the use of vegetated swales and retention basins and minimization of impermeable surfaces, to manage stormwater to maintain a site's predevelopment runoff rates and volumes.

The City of Los Angeles is a permittee under the current MS4 Permit for Los Angeles County (Order No. R4-2012-0175), as described further under Section 3.7.1.3, Los Angeles County Municipal Stormwater NPDES Permit (MS4 Permit).

State Strategies to Address Sea Level Rise

A range of State policies recommend and mandate that projects and programs located in coastal areas take sea level rise into account. California is at the forefront of the effort to find tools and instruments to reduce the impact of sea level rise on people, infrastructure and properties including executive orders and guidance documents. In 2008, Governor Schwarzenegger issued Executive Order S-13-08 directing state agencies to prepare guidance on sea level rise and to address sea level rise in any state projects located in vulnerable areas. Since the Proposed Project is within the California Coastal Zone, the California Coastal Commission is the primary agency that provides sea level rise policy guidance for the Proposed Project as it pertains to consistency with the CA Coastal Act.

The California Climate Adaption Strategy

In 2009 the California Climate Adaptation Strategy (2009) recommended that state agencies design policies to adapt to sea level rise and that all levels of government act to minimize sea level rise risk for infrastructure, properties and people. The document recommended five strategies: (1) a state policy to avoid future hazards and protect critical habitat; (2) a mandate to state agencies to devise statewide guidance for protecting existing critical ecosystems, existing coastal development, and future investments; (3) a mandate to state agencies to prepare sea level rise and climate adaptation

plans; (4) support for regional and local planning that address sea level rise impacts, and (5) a mandate to complete a statewide sea level rise vulnerability assessment every five years.

In relation to specific projects, the California Adaptation Strategy recommends that state agencies should generally not plan, develop, or build any new significant structure in a place on sites where future significant protection from sea level rise, storm surges, or coastal erosion would be required. However, the document also points out that there is an obligation to protect vulnerable shoreline areas where developments of regionally significant economic, cultural, or social value are currently located (NRA, 2009; p. 75).

National Research Council

Following a 2012 report by the National Research Council (NRC, 2012) that analyzed recent trends and forecasts of local sea level rise, in 2013 the Coastal and Ocean Working Group of the California Climate Action Team (CO-CAT) provided a coherent estimate of sea level rise projections for California (CO-CAT, 2013), and recommended that when incorporating sea level rise (SLR) projections into planning and decision making for projects, state agencies use year 2000 as a baseline and adopt the following projections:

Time Period	North of Cape Mendocino sea level rise projections	South of Cape Mendocino sea level rise projections
By 2030	From -0.13 to 0.75 feet (from -4 to + 23 cm)	From + 0.13 to 0.98 feet (from +4 to + 30 cm)
By 2050	From -0.10 to 1.57 feet (from -4 to + 23 cm)	From +0.39 to 2.00 feet (from +12 to + 61 cm)
By 2100	From +0.3 to 4.69 feet (from +10 to + 143 cm)	From +1.38 to 5.48 feet (from +42 to + 167 cm)

The CA State Safeguarding California Plan

The 2014 Safeguarding California Plan (2014, p. 155) framed adaptation strategies to sea level rise as actions to safeguard ocean and coastal ecosystems and resources as an integrated system. The plan recommends that state agencies improve their management practices with the goal of increasing the capacity of coastal systems to withstand and recover from climate impacts. It recommends supporting efforts to better understand evolving trends that could impact coastal and ocean ecosystems, and better information sharing among agencies.

In relation to coastal projects, the Plan suggests that "The state should not build or plan to build, lease, fund, or permit any significant new structures or infrastructure that will require new protection from sea-level rise, storm surges or coastal erosion during the expected life of the structure, beyond routine maintenance of existing levees or other protective measures, unless there is a compelling need (e.g. coastal-dependent marine terminals or as that must necessarily be sited in areas at risk)."(Natural Resources Agency, 2014; p. 179)

It also adds that "If the state is building or planning to build, lease, or permit structures that will require additional new expenditures for sea level rise protection during the expected life of the new structures, the state should ensure that the project proponent:

a. Minimizes risks through siting, design and engineering;

b. Ensures viable funding sources for building, monitoring and maintaining the new sea level rise protections;

c. Ensures that any new protections must consider how risk changes over time, ensure s that actions to reduce risk in the short-term do not increase risk in the long-term; and ensures that any new protections are capable of being augmented over time;

d. Designs protection in a manner that maximizes conservation of natural resources and public access." (NRA, 2014; p. 179)

CA Executive Order B-30-15

More recently, Governor Brown's April 2015 Executive Order B-30-15 addressed climate change and sea level rise adaptation, stating that state agencies shall take climate change into account in their planning and investment decisions. The order requires agencies to ensure that priority is given to actions that build climate preparedness and reduce greenhouse gas emissions, provide flexible and adaptive approaches, protect the state's most vulnerable populations, and promote natural infrastructure solutions.

California Coastal Act

As sea level rise increases the risk of flooding, coastal erosion, and saltwater intrusion and constitutes a threat for the California Coastal Zone, its potential impacts fall directly within the California Coastal Commission (CCC)'s planning and regulatory responsibilities of implementing the California Coastal Act. Many possible responses to sea level rise, such as construction of barriers or armoring, could have adverse impacts on coastal resources and also fall under the Coastal Commission's purview.

To address how coastal projects should take sea level rise into account, in 2015 the CCC issued its Sea Level Rise Policy Guidance (CCC, 2015) and established three important principles.

1. The CCC is committed to recognize and address sea level rise in planning and permitting decisions, to use locally relevant sea level rise estimates based on the best available science, to recognize and address scientific uncertainty and to act according to the precautionary principle.
2. The goal of the CCC is to avoid significant coastal hazard risks to new development where feasible, and if not feasible to minimize such hazards to both redevelopments and new developments. The Commission is also committed to take into account social and economic needs of the people of the state and to ensure that property owners understand and assume the risks of new development in hazardous areas, and mitigate their impacts on coastal resources.
3. The CCC's decisions maximize the protection of public access, recreation, and sensitive coastal resources; and maximize natural shoreline values, avoid expansion and minimize the perpetuation of shoreline armoring. The CCC also protects public trust lands and requires mitigation of unavoidable significant impacts to coastal resources.

According to the guidelines, to comply with Section 30253 of the Coastal Act, projects must be planned, located, designed, and engineered for the changing water levels and for any impact associated with sea level rise that might occur over the life of the development.

The guidelines include important mandates for project design and suggest a five step process to integrate sea level rise considerations into project design:

1. Establish the projected sea level rise range for the proposed project that includes:
    a. defining the expected project life (the CCC suggests more than 100 years for critical infrastructure);
    b. Determine sea level rise ranges;
2. Determine how physical impacts from sea level rise may constrain the project site;
3. Determine how the project may impact coastal resources, considering the influence of sea level rise (the analysis should consider: public access, coastal habitats, natural landforms, agricultural resources, water quality and groundwater, scenic resources);
4. Identify project alternatives that avoid resource impacts and minimize risks to the project (in practice identify adaptation options);
5. Finalize project design (CCC, 2015).

3.7.1.3 Local and Regional

Los Angeles Basin Water Quality Control Plan (Basin Plan)

The preparation and adoption of water quality control plans (Basin Plans) is required by the California Water Code (Section 13240) as prescribed by the CWA. Section 303 of the CWA requires states to adopt water quality standards that "consist of the designated uses of the navigable waters involved and the water quality criteria for such waters based upon such uses." According to Section 13050 of the California Water Code, Basin Plans consist of a designation or establishment of beneficial uses to be protected, water quality objectives to protect those uses, and a program of implementation needed for achieving the objectives for the waters within a specified area. Because beneficial uses, together with their corresponding water quality objectives, can be defined per federal regulations as water quality standards, the Basin Plans are regulatory references for meeting the state and federal requirements for water quality control. Beneficial uses of waters within the project study area and downstream receiving waters are shown in Table 3.7-3 in Section 3.7.2.2, Water Quality and Beneficial Uses. The Basin Plan specifies the water quality objectives for the all inland surface waters and enclosed bays and estuaries (including wetlands) in the Region (Los Angeles RWQCB 1995). Table 3.7-4 in Section 3.7.2.2, Water Quality and Beneficial Uses, lists the water quality constituents described in the Basin Plan and their objectives.

Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles

Discharges of treated or untreated groundwater generated from permanent, temporary dewatering operations or other applicable wastewater discharges not specifically covered in other general or individual NPDES permits are currently regulated under a regional general permit, General Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties) (Order No. R4-2013-0095, NPDES No. CAG994004).

Construction dewatering wastes (except stormwater) are regulated as low-threat discharges to surface waters. An NOI and Report of Waste Discharge must be submitted to the Los Angeles RWQCB to comply with this General Permit. Based on the depth to groundwater, it is anticipated

that the Proposed Project would require groundwater dewatering during construction, and would be subject to the requirements of this General Permit.

Los Angeles County Municipal Stormwater NPDES Permit (MS4 Permit)

The current Municipal Separate Storm Sewer System (MS4) Permit for Los Angeles County (Order No. R4-2012-0175) was adopted on November 8, 2012, became effective December 28, 2012, and will expire on December 28, 2017. Order No. R4-2012-0175 is the fourth iteration of the stormwater permit for the MS4s in the Los Angeles region, which includes the Los Angeles County Flood Control District, county of Los Angeles, and 84 incorporated cities (including the city of Los Angeles) within the county watersheds, excluding the city of Long Beach. The permit contains requirements that are necessary to improve efforts to reduce the discharge of pollutants in stormwater runoff to the maximum extent practicable (MEP) and achieve water quality standards. This permit requires that runoff is addressed during the major phases of urban development (planning, construction, and operation) in order to reduce the discharge of pollutants from stormwater to the MEP, effectively prohibit non-stormwater discharges, and protect receiving waters.

The MS4 Permit also includes construction requirements for implementation of the following minimum construction site BMPs for erosion, sediment, non-stormwater management, and waste management on all construction sites under one acre.

Erosion Controls	Scheduling Preservation of Existing Vegetation
Sediment Controls	Silt Fence Sand Bag Barrier Stabilized Construction Site Entrance/Exit
Non-Stormwater Management	Water Conservation Practices Dewatering Operations
Waste Management	Material Delivery and Storage Stockpile Management Spill Prevention and Control Solid Waste Management Concrete Waste Management Sanitary/Septic Waste Management

The permit also requires the design and implementation of specific post-construction controls to mitigate stormwater pollution, prior to project completion, for all “new development” and “redevelopment” projects that meet certain criteria as specified in the permit. During operation of new development or redevelopment, the permit prohibits non-stormwater discharges from the development (with some conditional exceptions), and requires BMPs to eliminate discharges to the MEP. Stormwater effluent must meet water quality–based effluent limitations (WQBELs), or water quality standards for discharge, and must not cause or contribute to the exceedance of water quality standards for receiving waters, as identified in the Los Angeles Basin Water Quality Control Plan (Basin Plan); also refer to Tables 3.7-3 (beneficial uses) and Table 3.7-4 (water quality objectives) in Section 3.7.2.2, Water Quality and Beneficial Uses. The permit requires each permittee to implement a Planning and Land Development Program for all new development, which requires permittees to:

1. Lessen the water quality impacts of development by using smart growth practices such as compact development, directing development towards existing communities via infill or redevelopment, and safeguarding of environmentally sensitive areas.
2. Minimize the adverse impacts from stormwater runoff on the biological integrity of Natural Drainage Systems and the beneficial uses of water bodies in accordance with requirements under CEQA (California Public Resources Code Section 21000 et seq.).
3. Minimize the percentage of impervious surfaces on land developments by minimizing soil compaction during construction, designing projects to minimize the impervious area footprint, and employing LID design principles to mimic predevelopment hydrology through infiltration, evapotranspiration and rainfall harvest and use.
4. Maintain existing riparian buffers and enhance riparian buffers when possible.
5. Minimize pollutant loadings from impervious surfaces such as rooftops, parking lots, and roadways through the use of properly designed, technically appropriate BMPs (including source-control BMPs such as good housekeeping practices), LID strategies, and treatment control BMPs.
6. Properly select, design, and maintain LID and hydromodification control BMPs to address pollutants that are likely to be generated, reduce changes to pre-development hydrology, assure long-term function, and avoid the breeding of vectors.
7. Prioritize the selection of BMPs to remove stormwater pollutants, reduce stormwater runoff volume, and beneficially use stormwater to support an integrated approach to protecting water quality and managing water resources in the following order of preference:
    a. On-site infiltration, bioretention and/or rainfall harvest and use.
    b. On-site biofiltration, off-site ground water replenishment, and/or off-site retrofit.

City of Los Angeles Development Construction Model Program

The City of Los Angeles (City) Development Construction Model Program addresses NPDES Phase II requirements on construction sites within incorporated city lands. BMPs for construction (as well as source control and treatment) are detailed in the City's Reference Guide for Stormwater Best Practices (LADPW, 2000). The BMPs are consistent with those developed by the state and county, and include erosion and sedimentation control measures, site management practices, materials and waste management, and general preventive maintenance and inspection.

City of Los Angeles Low-Impact Development Ordinance and Manual

In November 2011, the City of Los Angeles adopted the Stormwater Low Impact Development Ordinance #181899 with the stated purpose of:

- Requiring the use of LID standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff
- Reducing stormwater/urban runoff while improving water quality
- Promoting rainwater harvesting
- Reducing off-site runoff and providing increased groundwater recharge
- Reducing erosion and hydrologic impacts downstream
- Enhancing the recreational and aesthetic values in our communities

The City of Los Angeles institutionalized the use of LID techniques for development and redevelopment projects. Subsequent to the adoption of the Stormwater LID Ordinance, the City prepared the Development Best Management Practices Handbook, Low Impact Development Manual, dated June 2011, to describe the required BMPs (City of Los Angeles, 2011).

Local Strategies to Address Sea Level Rise

University of Southern California Sea Grant Program

The University of Southern California Sea Grant Program conducted a sea level rise vulnerability study for the City of Los Angeles (Grifman et al., 2013) with the goal of analyzing the physical, social, and economic impacts of sea level rise on the City of Los Angeles, with a specific focus on City-owned assets like the port, power generation facilities, wastewater treatment facilities, and wastewater and stormwater conveyance infrastructure. According to the vulnerability assessment, the City's roads and water systems (wastewater, stormwater, and potable water), as well as the City's cultural assets, are vulnerable to impacts from the combined effect of sea level rise and storm surges. Parks and open space, while in vulnerable locations, are less vulnerable to flooding impacts since they can be restored relatively quickly. Port and City energy facilities also have relatively low vulnerability to sea level rise. However, City wastewater infrastructure is at risk. Specifically, wastewater pumping plants are at risk of being damaged during extreme wet weather events that inundate electrical components. Furthermore, such damage could result in wastewater spills with negative environmental and economic consequences.

Los Angeles Department of Public Works, Bureau of Sanitation

A climate change asset vulnerability study conducted by the Los Angeles City Bureau of Sanitation (LASAN) (USEPA, 2016) on its wastewater and stormwater facilities in 2015, resulted in findings that future storm surges, sea level rise, and tsunamis pose a quantifiable risk to LASAN assets and operations. The final report summarizing the findings of the study projects a 0.5 m (1.64 feet) rise in sea level in the Venice Beach Pumping Plant area by 2050 (based on NOAA estimates of 0.88mm/year sea level rise trends in the Los Angeles area). The study quantified the risk or asset vulnerability presented by this and other climate change effects, and identified and provided cost estimates for recommended adaptive measures that could reduce climate and sea level rise risks to LASAN. Recommended sea level rise adaptation measures include: installing temporary flood barriers, designing a wet weather plan specific to each installation, constructing perimeter walls, improving and protecting the back-up power of its plants, or using watertight enclosures to further protect electrical equipment, instrumentation and controls (USEPA, 2016).

Los Angeles Department of City Planning

The Los Angeles City Council recently adopted a motion that funds the Department of City Planning to conduct climate change and sea level rise studies as part of the update of the Venice Local Coastal Program, which will directly address future design measures that will help mitigate potential sea level rise impacts within Venice Coastal Zone.

3.7.2 Environmental Setting

This section describes the hydrology and water quality settings of the Proposed Project area. It is intended to assist the impact analysis and in designing necessary mitigation measures.

3.7.2.1 Watershed

The Project Site is located within the Marina del Rey subwatershed, which covers approximately 2.9 square miles in the coastal plain of the Los Angeles Basin (refer to Figure 3.7-1, Watersheds and Surface Waters). The Marina del Rey watershed is a small sub-watershed located in the larger, Santa Monica Bay watershed (Weston, 2014). Its tributary area is served by an MS4 that drains to Marina del Rey Harbor and is approximately 1,409 acres and consists of portions of the cities of Culver City and Los Angeles, as well as portions of the unincorporated County of Los Angeles (County). The Marina del Rey watershed is bordered by the Santa Monica Bay Watershed to the west and the Ballona Creek Watershed to the north and east. The Marina del Rey harbor is open to the Santa Monica Bay through the main channel and shares a common breakwater with Ballona Creek. The Marina del Rey watershed also includes the Venice Canals and the tributary area to the Ballona Lagoons, which discharge to the Marina del Rey Harbor, near the exit to the Santa Monica Bay. (Weston, 2014).

3.7.2.2 Surface Waters and Local Hydrology

Surface waters adjacent to the Project Site include the Grand Canal and Ballona Lagoon (refer to Figure 3.7-1, Watersheds and Surface Waters). The Grand Canal extends 2,000 feet north from Ballona Lagoon to the Washington Boulevard tide gates, and averages about 50 feet wide (Watearth, 2016). The Grand Canal is exposed to oceanic currents via the tidal gates at the mouth of Ballona Lagoon that connect to Marina Del Rey and Santa Monica Bay (Watearth, 2016). The Grand Canal and Ballona Lagoon are connected at the South Esplanade, approximately 150 feet southeast of the Project Site. Ballona Lagoon is a tidal channel situated on the Silver Strand Peninsula, adjacent to Marina del Rey Harbor (CWIS, 2016). Both the Ballona Lagoon and Grand Canal are direct tributaries to the Marina del Rey Harbor entrance and the Pacific Ocean. In addition, the lagoon channel is the source of water for the Venice Canals (located to the north of the Project Site) via the Grand Canal; tidal waters enter the lagoon at the southern end through tidal gates connected to the Marina del Rey harbor channel entrance (CWIS, 2016). The Grand Canal shares a tide gate with Ballona Lagoon as it empties into the Pacific Ocean at the Marina del Rey harbor channel entrance. Surface flows within the areas surrounding the Project Site drain via sheetflow or area storm drains to the Grand Canal.

Water Quality and Beneficial Uses

The Project Site discharges to the Grand Canal, which connects to Ballona Lagoon and then to Marina del Rey Harbor, located immediately to the south. Ballona Lagoon and Marina del Rey

Harbor are included on the 303(d) List for the water quality impairments shown below in Table 3.7-1. Multiple TMDLs are in effect for the Ballona Creek Watershed.

Table 3.7-1. Overview of Water Quality Impairments in Project Area

Water Body	Listed Impairments	Potential Sources	Estimated EPA TMDL Completion
Ballona Lagoon	Exotic Vegetation	Nonpoint Source	2019
	Habitat Alterations	Nonpoint Source	2019
	Hydromodification	Nonpoint Source	2019
	Reduced Tidal Flush	Nonpoint Source	2019
	Trash	Nonpoint Source	2019
Marina del Rey Harbor	Chlordane (tissue and sediment)	Nonpoint Source	EPA TMDL approval 2005
	Copper (sediment)	Nonpoint Source	EPA TMDL approval 2006
	DDT (tissue)	Nonpoint Source	EPA approved TMDL has made a finding of non-impairment for this pollutant
	Dieldrin (tissue)	Nonpoint Source	EPA approved TMDL has made a finding of non-impairment for this pollutant
	Fish Consumption advisory	Nonpoint Source	EPA TMDL approval 2005
	Indicator Bacteria	Nonpoint Source	EPA TMDL approval 2004
	Lead (sediment)	Nonpoint Source	EPA TMDL approval 2006
	PCBs (polychlorinated biphenyls) (tissue and sediment)	Nonpoint Source	EPA TMDL approval 2006
	Sediment Toxicity	Nonpoint Source	EPA TMDL approval 2005
	Zinc (sediment)	Nonpoint Source	EPA TMDL approval 2006

Source: SWRCB 2011.

The City of Los Angeles requested water quality sampling on June 5, 2015 before the project began. To establish baseline water quality conditions within the Grand Canal, water quality samples were obtained from three locations near the project area: Site 1 was at a culvert on Hurricane Street, Site 2 was at the existing Venice Pumping Plant (VPP) at the upstream incoming tide, and Site 3 was at the VPP station at the downstream outgoing tide. The following water quality parameters were determined for the baseline: acidity (pH), temperature, dissolved oxygen (DO), turbidity, and total suspended solids (TSS). A visual assessment for any floating hydrocarbons was also performed. The complete results of this study are included in the *Hydrology Technical Memorandum* prepared by Watearth, (Appendix K of Appendix H), including pH, Temperature, Dissolved Oxygen (DO), and Turbidity. In addition to the project sampling, water quality samples were collected as part of the Grand Canal West Bank Erosion Control Project between May 29th and July 17th, 2015. Complete water quality results from the Grand Canal West Bank Erosion Control Project are in Table 3.7-2.

Table 3.7-2. Project Area Water Quality Sampling Results

Location	Date	pH	Temperature (^{0}F)	DO	TSS (mg/L)	Turbidity (NTU)	Floatables (ug/L)

Source: Los Angeles Regional Water Quality Control Board Basin Plan, 1995.

The Basin Plan specifies the water quality objectives for the all inland surface waters and enclosed bays and estuaries (including wetlands) in the Region (Los Angeles RWQCB 1995). Table 3.7-4 lists the water quality constituents described in the Basin Plan and their objectives.

Table 3.7-4. Water Quality Objectives Provided in the Water Quality Control Plan for the Los Angeles RWQCB Basin Plan

Water Quality Constituent	Water Quality Objective
Ammonia	For inland surface waters not characteristic of freshwater, the four-day average concentration of un-ionized ammonia shall not exceed 0.035 mg/L and the one-hour average concentration shall not exceed 0.233 mg/L.
Bacteria	In marine waters designated REC-1 the fecal coliform concentration based on a minimum of not less than five samples for any 30-day period shall not exceed a geometric mean of 200/100 ml, nor shall more than 10 percent of the total number of samples taken during any 30-day period exceed 400/100 ml.
Bioaccumulation	Toxic pollutants shall not be present at levels that will bioaccumulate in aquatic life to levels that are harmful to aquatic life or human health.
Biochemical Oxygen Demand	Waters shall be free of substances that result in increases in the BOD, which adversely affect beneficial uses.
Biostimulatory Substances	Waters shall not contain biostimulatory substances in concentrations that promote aquatic growth to the extent that such growth causes nuisance or adversely affects beneficial uses.
Chemical Constituents	Surface waters shall not contain concentrations of chemical constituents in amounts that adversely affect any designated beneficial use.
Chlorine, Total Residual	Chlorine residual shall not be present in surface water discharges at concentrations that exceed 0.1 mg/L and shall not persist in receiving waters at any concentration that causes impairment of beneficial uses.
Color	Waters shall be free of discoloration that causes nuisance or negatively affects beneficial uses.
Exotic Vegetation	Exotic vegetation shall not be introduced around stream courses to the extent that such growth causes nuisance or adversely affects beneficial uses.
Floating Material	Waters shall not contain floating material in amounts that cause nuisance or negatively affect beneficial uses.
Methylene Blue Activated Substances (MBAS)	Waters shall not have MBAS concentrations greater than 0.5 mg/L in waters designated MUN.
Oil and Grease	Waters shall not contain oils, greases, waxes, or other materials in concentrations that cause nuisance, result in a visible film or coating on the surface of the water or on objects in the water, or otherwise negatively affect beneficial uses.
Oxygen, Dissolved (DO)	At a minimum, the mean annual dissolved oxygen concentration of all waters shall be greater than 7 mg/L, and no single determination shall be less than 5.0 mg/L, except when natural conditions cause lesser concentrations.
Pesticides	No individual pesticide or combination of pesticides shall be present in concentrations that adversely affect beneficial uses. There shall be no increase in pesticide concentrations found in bottom sediments or aquatic life.
pH	The pH of inland surface waters shall not be depressed below 6.5 or raised above 8.5 as a result of waste discharges. Ambient pH levels shall not be changed more than 0.5 units from natural conditions as a result of waste discharge.
Polychlorinated Biphenyls (PCBs)	The purposeful discharge of PCBs (the sum of chlorinated biphenyls whose analytical characteristics resemble those of Aroclor-1016, Aroclor-1221, Aroclor-1232, Aroclor-1242, Aroclor-1248, Aroclor-1254, and Aroclor-1260) to waters of the Region, or at locations where the waste can subsequently reach waters of the Region, is prohibited.
	Pass-through or uncontrollable discharges to waters of the Region, or at

Water Quality Constituent	Water Quality Objective
	locations where the waste can subsequently reach water of the Region, are limited to 70 pg/L (30 day average) for protection of human health and 14 ng/L and 30 ng/L (daily average) to protect aquatic life in inland fresh waters and estuarine waters respectively.
Radioactive Substances	Radionuclides shall not be present in concentrations that are deleterious to human, plant, animal, or aquatic life or that result in the accumulation of radionuclides in the food web to an extent that presents a hazard to human, plant, animal, or aquatic life.
Solid, Suspended, or Settleable Materials	Waters shall not contain suspended or settleable material in concentrations that cause nuisance or adversely affect beneficial uses.
Taste and Odors	Waters shall not contain taste- or odor-producing substances in concentrations that impart undesirable tastes or odors to fish flesh or other edible products of aquatic origin, or that cause nuisance, or otherwise negatively affect beneficial uses.
Temperature	The natural receiving water temperature of all regional waters shall not be altered unless it can be demonstrated to the satisfaction of the Regional Board that such alteration in temperature does not adversely affect beneficial uses.
Toxicity	All waters shall be maintained free of toxic substances in concentrations that produce detrimental physiological responses in human, plant, animal, or aquatic life.
Turbidity	Waters shall be free of changes in turbidity that cause nuisance or negatively affect beneficial uses. Increases in turbidity attributable to controllable water quality factors shall not exceed the following limits: where natural turbidity is between 0 and 50 NTU, increases shall not exceed 20%. Where natural turbidity is greater than 50 NTU, increases shall not exceed 10%.

3.7.2.3 Hydrology

Building Site Hydrology

The Project Site and three associated Laydown Areas (see Figure 2-2, Chapter 2 [Project Description] of this EIR) are currently vacant lots and the vegetation is mostly native vegetation within the intertidal zone and non-native above the intertidal zone. Their impervious cover is zero-percent. Elevations within the Project Site range from a low of approximately four feet in the southwestern portion of the site to a high of approximately nine feet near the center of the site. Elevations are similar for Laydown Areas 1 and 2. The area surrounding the Project Site is relatively low, only reaching heights of five feet. The approximate elevation of the bank area of the Grand Canal is five feet with a gradual slope eventually reaching one-foot above mean sea level. The elevation for Laydown Area 3 located off-site in the City of Culver City is approximately 95 feet. Rainfall and subsequent on-site stormwater runoff at the Project Site is comprised of overland sheet flow, which generally flows southwest to northeast towards the Grand Canal and/or to an off-site storm drain at Hurricane Street and Esplanade. Flows from Laydown Area 1 drain to the Ballona Lagoon, while flows from Laydown Area 2 flow to the Grand Canal. Flows from Laydown Area 3 flow to stormwater drains located along Jefferson Boulevard. None of these vacant parcels include water quality or stormwater controls, such as stormwater BMPs, LID features, or hydromodification management facilities. Stormwater detention and other flood control features are also not present on-site.

As shown in Table 3.7-5, existing conditions peak discharges from the Project Site are estimated at 72.87 cubic feet per second (cfs), 165.64 cfs, and 263.83 cfs for the two-year, 24-hour, ten-year, 24-hour, and 100-year, 24-hour design storm events, respectively. As shown in Table 3.7-5, the existing two-year peak flow is 0.06 cfs, the existing ten-year peak flow is 0.14 cfs, and the existing 100-year peak flow is 0.24 cfs. Similar flows are expected for the Laydown Areas 1 and 2. There are no known existing capacity issues associated with the stormwater receiving facility located in Hurricane Street, which receives flows from the Project Site. As described above, there are no storm drains serving Laydown Areas 1 or 2, while flows from Laydown Area 3 drain to Jefferson Boulevard.

Table 3.7-5. Existing Peak Discharges and Flows (cfs) for Project Site

Existing Conditions	2-year, 24-hour	10-year, 24-hour	100-year, 24-hour
Peak Discharges	72.87 cfs	165.64 cfs	263.83 cfs
Peak Flow	0.06 cfs	0.14 cfs	0.24 cfs
Source: Watearth, 2016			

Off-site flows into or through the Project Site and laydown areas are minimal. The drainage inlets in roadways adjacent to the Project Site and laydown areas include screens or grates to prevent or limit trash from entering the storm drain system and discharging to Grand Canal or Ballona Lagoon or Ballona Creek (within the Culver City area).

3.7.2.4 Grand Canal

The Grand Canal is part of the Venice Canals system, which is hydrologically connected to Santa Monica Bay and the Pacific Ocean via Ballona Lagoon and the Marina Entrance Channel. Local surface flow is directed into the canals from local streets and storm drains. As a coastal waterway, the Grand Canal is subject to diurnal tidal fluctuation. High tides, combined with significant rainfall events, also lead to local flooding problems. Tide gates are positioned at the Marina Entrance Channel (to the South), and at the Washington Street Bridge (to the North). The Grand Canal Esplanade right-of way is 21.3 meters (70 feet [ft]) in width, while the channel bottom is approximately 14.6 m (48 ft) in width and from zero to 1.7 meters (5.5 ft) in depth (Los Angeles Bureau of Engineers [LABOE], 2013).

The Grand Canal Esplanade right-of-way is comprised of submerged lands, as well as unpaved banks, and paved sidewalks. Ten-foot wide easements occur along both banks, which includes the banks and (five-foot wide) sidewalks. The banks are unlined, while the channel bottom ranges from gravelly to soft bottom mud with varying amounts of sand and gravel. Areas of exposed mud flat are extensive at low tide, but are restricted to a narrow, canal bottom/bank transition (LABOE, 2013).

3.7.2.5 Soils

No mapping is available from the Natural Resources Conservation Service for the study area. Based on soils observed in the wetland sample points, the soils on-site consisted of sandy clay and loams and fill (see Appendices D, *Jurisdictional Delineation* and G, *Geotechnical Engineering Report – Venice Auxiliary Pumping Plant* of this EIR). As noted in Appendix G of this EIR, artificial fill soils exist within the site as the result of previous construction and/or previous construction activities. In general, the depth of fill is expected to be approximately three to four feet. The fill materials generally consist of silty sand and sand with some construction debris. Alluvial sediments encountered in the borings contain primarily coarse-grained soils consisting of gravels, sands, and

silty sands with interlayered fine-grained soils consisting of silts and clays. Soil samples were not taken for the laydown areas since no construction activities are proposed there. It is expected that the on-site soils at these locations (Laydown Areas 1 and 2) would be similar in nature to that of the Project Site, while soils at Laydown Area 3 are unknown.

3.7.2.6 Floodplain

The Project Site (including Laydown Areas 1 and 2) is located in Zone X (areas outside the 1-percent annual chance floodplain) within the regulatory 500-year floodplain of the Grand Canal. The diversion structure is proposed to be located within the Grand Canal (below grade). The Flood Insurance Rate Map (FIRM) Panel shown in the exhibit is 6037C1752F. These panels were updated September 26, 2008. Areas shown within the shaded Zone X are the areas between the limits of the base flood and the 0.2-percent annual chance, or 500-year floodplain. This means the area is classified as a moderate flood hazard area.

3.7.2.7 Tsunami, Seiche, Sea Level Rise and Mudflow

Elevations within the Project Site range from a low of approximately four feet in the southwestern portion of the site to a high of approximately nine feet near the center of the site. Similar elevations occur within Laydown Areas 1 and 2. As such, the Project Site and Laydown Areas 1 and 2 are not located within a landslide/mudflow hazard zone. Similarly, Laydown Area 3, located in Culver City is not located within a landslide or mudflow hazard zone.

A tsunami is a series of traveling ocean waves of great length and long period, which are generated by disturbances associated with earthquakes in oceanic and coastal regions. The Project Site (including Laydown Areas 1 and 2) is approximately 0.2 mile east from the Pacific Ocean and is located within a designated tsunami hazard zone. Laydown Area 3 is not located within a tsunami hazard zone.

A seiche is an oscillation of a body of water. Seiches occur most frequently in enclosed or semi-enclosed basins such as lakes, bays, or harbors and may be triggered by strong winds, changes in atmospheric pressure, earthquakes, tsunami, or tides. The Project Site and Laydown Areas 1 and 2 are adjacent to Grand Canal and Ballona Lagoon, which are semi-enclosed water bodies. The Project Site is also approximately 0.2 mile west of the Marina del Rey Harbor, but is separated from the harbor by Grand Canal and Ballona Lagoon, residential structures, and streets. Laydown Area 3 is located in Culver City about 750 feet west of Ballona Creek, a channelized stormwater conveyance facility. The Venice, California area is expected to be exposed to the risk of sea level rise, combined with the increased effects of a 100-year storm event based on information in the United States Geological Survey (USGS) and University of Southern California (USC) studies (Watearth, 2016). The Project Site is also located near Ballona Lagoon, which is classified as a major channel. Major water bodies are exposed to more flux in tides and may therefore have an increased risk of flooding during a 100-year flooding event. Sea level rise is expected to occur by the Intergovernmental Panel on Climate Change (IPCC). Projections range from 18 centimeters (cm) (0.59 ft) at the lowest projection to 59 cm (1.94 ft) for the highest projection by the year 2100. The USGS has mapped out the inundation risk of the project area, which could experience the effects of sea level rise if flood levels inundate at 200 centimeters (16.6 ft). However, because of the proximity to Grand Canal, a risk of inundation at 150 centimeters (12.5 ft) must be taken into account (Watearth, 2016). Sea level rise is not expected to affect Laydown Area 3 located in Culver City.

3.7.3 Environmental Impact Analysis

3.7.3.1 Methodology

Impacts were analyzed qualitatively based on professional judgment in light of the hydrologic and hydraulic analyses prepared for project design. The analysis focused on issues related to surface water hydrology, flood hazards, and water quality. The key construction-related impacts were identified and evaluated qualitatively based on the physical characteristics of the Project Site and the magnitude, intensity, location, and duration of activities.

The surface water hydrology impact analysis considers changes in drainage patterns, changes in stormwater volumes and capacity, creation of new impervious surfaces, and changes in nearby water bodies. Information from the *Hydrology Technical Memorandum* (Appendix H of this EIR) provided the data.

Information from the *Hydrology Technical Memorandum* also provided data used in the flood risk impact analysis. The impact analysis considers changes in the drainage system and layout to characterize potential effects on flood risk.

Impacts of the Proposed Project on surface water quality were analyzed using available information on potential existing sources of pollution and current water quality conditions in the project area. These conditions were then compared to potential project-related sources of pollution during construction, such as sediments and other construction materials, and operation, such as operation and maintenance activities, trash, and storage of hazardous materials. The Proposed Project was analyzed for potential impacts on beneficial uses and water quality objectives (i.e., pollutants of concern) of receiving waters. Receiving waters with CWA Section 303(d) impaired water quality were identified, along with the impairment (pollutant/stressor) and an indication of whether the impairment has the potential to be further affected by the Proposed Project.

3.7.3.2 Screening Analysis

As noted in Section Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.7.3.3 Thresholds of Significance

Thresholds of significance used to analyze impacts are based on CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006).

According to Appendix G of the CEQA Guidelines, a project would normally have a significant impact on hydrology and water quality if it would:

HYDRO-1. Violate any water quality standards or waste discharge requirements;

HYDRO-2. Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on-site or off-site;

HYDRO-3. Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site;

HYDRO-4. Create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff;

HYDRO-5. Otherwise substantially degrade water quality;

HYDRO-6. Place within a 100-year flood hazard area structures that would impede or redirect floodflows;

HYDRO-7. Contribute to inundation by seiche, tsunami, sea level rise or mudflow.

This threshold has been modified to also address sea level rise, and potential tsunami impacts in combination with future conditions created by sea level rise.

According to the *L.A. CEQA Thresholds Guide* (2006), a project would normally have a significant impact on hydrology and water quality if it would:

Sedimentation

HYDRO-8. Constitute a geologic hazard to other properties by causing or accelerating instability from erosion; or

HYDRO-9. Accelerate natural processes of wind and water erosion and sedimentation, resulting in sediment runoff or deposition that would not be contained or controlled on-site.

Surface Water Quality

HYDRO-10. Result in discharges that would create pollution, contamination or nuisance as defined in Section 13050 of the California Water Code (CWC) (see definitions on page G.2-4 of the City's Thresholds) or that cause regulatory standards to be violated, as defined in the applicable NPDES stormwater permit or Water Quality Control Plan for the receiving water body.

Surface Water Hydrology

HYDRO-11. Cause flooding during the projected 50-year developed storm event, which would have the potential to harm people or damage property or sensitive biological resources;

HYDRO-12. Substantially reduce or increase the amount of surface water in a water body; or

HYDRO-13. Result in a permanent, adverse change to the movement of surface water sufficient to produce a substantial change in the current or direction of water flow.

3.7.3.4 Impacts and Mitigation

The assessment of impacts is based on the assumption that the Proposed Project would include the following:

- The City will reduce construction stormwater discharges to the maximum extent practicable in accordance with the Los Angeles County MS4 Permit for the landside portions of the Proposed Project. The following BMPs for erosion control, sediment control, non-stormwater

management, and waste management during construction will be implemented as part of the Proposed Project:

Erosion Controls	Scheduling Preservation of Existing Vegetation
Sediment Controls	Silt Fence Sand Bag Barrier Stabilized Construction Site Entrance/Exit
Non-Stormwater Management	Water Conservation Practices Dewatering Operations
Waste Management	Material Delivery and Storage Stockpile Management Spill Prevention and Control Solid Waste Management Concrete Waste Management Sanitary/Septic Waste Management

- Other standard operating procedures and BMPs for City construction projects will be implemented, including: BMPs for in water work, such as turbidity curtains and trash booms.
- The City will perform construction activities within the Grand Canal (a navigable water of the United States) in accordance with provisions of Section 404 (of the CWA), and Section 10 (of the RHA) permit from the USACE.
- The City will secure a Section 401 (of the CWA) Water Quality Certification from the LARWQCB for construction activities within the Grand Canal and will comply with conditions of that certification, including standard WDRs.
- The City will also comply with General Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties (NPDES)
- Consistent with Standard Urban Stormwater Mitigation Plan (SUSMP) standards, the Proposed Project design will include the following Low Impact Development (LID) features:
    - Lined Bioretention or Planter Box, with a vegetated filter strip as a pre-treatment BMP
    - All impervious cover on the Project Site would be disconnected from impervious surfaces and drain through the vegetated filter strip by overland flow

3.7.3.5 Construction Impacts

The analysis below describes the temporary and permanent impacts on hydrology and water quality anticipated as a result of construction of the Proposed Project. Construction activities with the potential to affect hydrology and water quality would generally include:

- Soil-disturbing activity (e.g., excavation, grading, fills), which can lead to erosion and sedimentation;

- Excavation within and along the slope of the Grand Canal, which could result in impacts that affect water quality in an impaired water body from sedimentation.
- Excavation in areas of high groundwater, which could result in impacts that affect groundwater quality or quantity from dewatering activities and direct exposure of groundwater to sediment and other contaminants;
- Use of construction-related hazardous materials, which could result in spills that would affect surface waters and infiltrate to groundwater aquifers;
- Generation of pollutants of concern during construction, such as sediment, trash, sanitary waste, dry and wet concrete waste, and chemicals, which could degrade water quality.

HYDRO-1. Would the project violate any water quality standards or waste discharge requirements?

Construction at the Project Site would begin with site clearing, shoring, and excavation. As described in Chapter 2, Project Description, excavation would occur in stages, with shoring installed at each stage to prevent soil collapse or groundwater seepage into the excavation area. Dewatering methods would be required at all times during construction, to promptly remove and dispose of all water from any source entering the excavation sites. A cofferdam would be constructed to ensure dry bedding conditions to construct underground diversion structure foundations. The cofferdam would have two cells, one on land and the other in the Grand Canal in order to minimize risk of inundation. The land cell would be constructed first followed by the Grand Canal cell. The wet well, valve vault, and inlet pipe would be constructed within the land cell. Once all equipment is constructed, backfilling and compacting would begin. Once construction on the land cell is complete, the Grand Canal cell would be excavated and the diversion structure would be constructed. Once the diversion structure is in place, a modular channel insert would be constructed in order to reduce the risk of spills. The final step would be to seal the junction structure, backfill, and compact. The land cell shoring steel would be removed as needed to a minimum of five feet below grade minimizing the possibility of settlement and the Grand Canal cell shoring can be removed. The channel trapezoidal bottom would be restored to existing conditions. Surface improvements would occur next. Construction above grade would include the electrical building that would be concrete or masonry construction.

Land Side Construction Activities

Construction activities associated with the Proposed Project such as grading and excavation, construction of below ground facilities, filling and compaction, utility installation and construction of above ground facilities and building could result in increased polluted stormwater runoff. In case of heavy rain or wind conditions, when the Project Site is excavated or otherwise disturbed by construction activities, the potential for erosion and sediment transport from the Project Site and laydown areas could increase, if the excavated area is not below grade (below ground surface). Stormwater runoff (or wind) could carry the exposed or eroded sediments to the storm drain system and ultimately to the Grand Canal, Ballona Lagoon, and Marina del Rey Harbor or Ballona Creek (the location of Laydown Area 3). Erosion and sedimentation affects water quality through interference with photosynthesis, oxygen exchange, and the respiration, growth, and reproduction of aquatic species. Additionally, other pollutants, such as nutrients, trace metals, and hydrocarbons, can attach to sediment and be transported downstream, which could contribute to degradation of water quality. As such, construction activities could violate water quality standards or waste discharge requirements and impacts would be potentially significant.

In addition to potential pollutant contributions from disturbed areas, the delivery, handling, and storage of construction materials and wastes, as well as the use of construction equipment, could introduce a risk for stormwater contamination that could affect water quality. Spills or leaks from heavy equipment and machinery can result in oil and grease contamination. Some hydrocarbon compound pollution associated with oil and grease can be toxic to aquatic organisms at low concentrations. Staging areas or building sites can also be the source of pollution because of the use of paints, solvents, cleaning agents, and metals during construction. Materials from soil excavation could contain hazardous materials that may be exposed to stormwater. Larger pollutants, such as trash, debris, and organic matter, are also associated with construction activities. Furthermore, concrete used for structures, footings, and other paving materials could be potential sources of water quality pollution if any of these materials were spilled or deposited on unprotected surfaces. Other potential effects include health hazards and aquatic ecosystem damage associated with introduction of bacteria, viruses, and vectors if waste management is not adequately implemented. As such, construction activities could violate water quality standards or waste discharge requirements and impacts would be potentially significant.

Erosion and sediment control BMPs would be required to be implemented to protect water quality. Erosion control, sediment control, non-stormwater management, and waste management construction BMPs shall be implemented to prevent pollutants from being discharged to waterways from stockpiles, material, equipment storage and use, trash, and other pollutant sources. Erosion and sediment control BMPs would be implemented in accordance with the MS4 Permit and City of Los Angeles Development Construction Model Program. The BMPs are consistent with those developed by the state and county, and include erosion and sedimentation control measures, site management practices, materials and waste management, and general preventive maintenance and inspection. These measures would prevent excavated and eroded soils, construction materials, or debris from being transported to receiving waters, which include the Grand Canal, Ballona Lagoon and Ballona Creek (associated with Laydown Area 3 in Culver City). As such, implementation of BMPs required by the MS4 Permit would reduce potential impacts to water quality to less than significant; no mitigation measures are required.

Construction activities are anticipated to require dewatering. As such, construction activities could violate water quality standards or waste discharge requirements and impacts would be potentially significant. However, compliance with the General Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties (Order No. R4-2013-0095, NPDES No. CAG994004) would ensure that the Proposed Project would not violate any water quality standards and would also reduce the potential for the Proposed Project to affect the quality of receiving waters during construction activities. Therefore, impacts would be less than significant; no mitigation measures are required.

As noted above, compliance with existing regulatory requirements, such as implementation of erosion and sediment control BMPs as required by the MS4 Permit and Dewatering Permit, would reduce impacts of the Proposed Project in regards to violation of a water quality standard or waste discharge requirement to **less than significant; no mitigation measures are required.**

In-Water Construction Activities

The construction of a temporary cofferdam in the Grand Canal would require installation of sheeting that would disturb existing sediments in the Grand Canal, which could impair water quality. In addition, once the cofferdam is in place, scour along the cofferdam could result, depending on tidal,

canal, or wave-induced current conditions. Construction of the cofferdam, placement of the diversion structure, and backfill and soil compaction within the Grand Canal would last approximately three months. Following its construction, the Grand Canal channel bottom would be restored to its original elevation and the diversion would not protrude into the water column.

Construction of the coffer dam could affect water quality if protection measures are not implemented. Scour and erosion control would be required as part of the cofferdam construction. Proposed sheeting in Grand Canal would result in short-term disturbance of localized sediments, which could adversely affect water quality by temporarily re-suspending sediments, thereby increasing turbidity. In addition, chemicals that are present in the sediments could be released to the water column during resuspension, which could temporarily degrade water quality. Suspended sediments in the water column can lower levels of dissolved oxygen, increase salinity, increase concentrations of suspended solids, and possibly release chemicals present in sediments into the water. The degree of turbidity resulting from the suspended sediments would vary depending on the disturbance to the sediments and would also depend on the methods used, the quality of equipment, and the care of the operator. In most cases, increased turbidity levels would be relatively short-lived and generally confined to within a few hundred yards of the activity. After initial high-turbidity levels, sediments would disperse and background levels would be restored. As such, construction activities could violate water quality standards or waste discharge requirements and impacts would be potentially significant.

The Proposed Project would be required to obtain a Section 10 permit from the USACE for dredging and placement of subsurface structures in navigable waters and a Section 404 permit (likely Nationwide Permit 33 [for cofferdams]) from the USACE for the discharge of dredged materials. In addition, the Proposed Project would be required to obtain a RWQCB water quality certification (Section 401 [see below]) for the federal permits from the USACE. A RWQCB water quality certification would specify methods for ensuring the protection of water quality during construction activities in Grand Canal, including water quality monitoring requirements. In addition, specific conditions would include the use of BMPs to minimize the discharge of construction materials from construction activities, control of floating debris, discharge of displaced water produced during construction to minimize discharge of pollutants to the Grand Canal, and provision of spill containment and cleanup equipment to control potential accidental spills.

Although temporary water quality impacts related to suspended solids in the water column would be expected, impacts related to resuspension of sediments would be reduced to a less than significant level with implementation of the appropriate regulatory permits, including the Section 401 Water Quality Certification. The Section 401 Water Quality Certification would require implementation of BMPs that would reduce water quality impacts associated with construction of the coffer dam. Common BMPs utilized may include use of silt curtains in addition to those previously identified.

With the adherence to USACE and RWQCB permit requirements associated with Sections 10, 401, and 404, **impacts associated with the Proposed Project related to violation of a water quality standard or waste discharge requirement would be less than significant and no mitigation measures are required.**

HYDRO-2. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on-site or off-site?

Land Side Construction Activities

The Project Site is relatively flat and would remain flat following construction activities. However, the Proposed Project requires shoring and excavation for construction of the below ground facilities. Shoring would be installed around the Project Site, after which excavation to a depth of approximately 25 feet and dewatering of the site would occur. Preliminary earthwork plans indicate that the Proposed Project would require approximately 10,000 cubic yards of soil to be excavated of which approximately 2,300 cubic yards would be stockpiled at Laydown Area 1. Approximately 7,700 cubic yards of soil would be stockpiled at Laydown Area 3.

Soil erosion is the process by which soil particles are removed from the land surface by wind, water or gravity. The rate of erosion increases when land is cleared or altered and left unprotected. Construction sites, if unprotected, can erode at rates in excess of one hundred times the natural background rate of erosion. Sediment resulting from excessive erosion is a pollutant. Stormwater runoff (or wind) could carry the exposed or eroded sediments to the storm drain system and ultimately to the Grand Canal, Ballona Lagoon, Marina del Rey Harbor, and Ballona Creek (for Laydown Area 3, located in Culver City). Erosion and sedimentation affects water quality through interference with photosynthesis, oxygen exchange, and the respiration, growth, and reproduction of aquatic species. Additionally, other pollutants, such as nutrients, trace metals, and hydrocarbons, can attach to sediment and be transported downstream, which could contribute to degradation of water quality. Although the Proposed Project does not entail altering the course of a stream or river, it could result in potentially significant impacts related to substantial erosion or siltation to on-site or off-site locations.

Compliance with existing regulations would reduce the potential for erosion, sediment transport, and pollutants in stormwater runoff to receiving waters from activities associated with the Project Site or Laydown areas. Construction erosion and sedimentation control measures, site management practices, materials and waste management BMPs would be implemented at the Project Site, as required by the NPDES MS4 Permit. Compliance with existing regulatory requirements, such as implementation of erosion and sediment control BMPs as required by the MS4 Permit would reduce impacts related to the Proposed Project's potential to substantially alter the existing drainage pattern of the site or area. **Therefore, impacts would be less than significant and no mitigation is required.**

In-Water Construction Activities

Water flowing in the Grand Canal would be diverted around the temporary cofferdam structure by the presence of the sheeting. Construction of the cofferdam could substantially alter the existing drainage pattern of the canal that would potentially result in erosion or siltation. The impacts of erosion or siltation from the cofferdam installation were previously described above and were determined to be potentially significant. Although temporary erosion and siltation impacts related to suspended solids in the water column would be expected, impacts related to resuspension of sediments would be reduced to a less than significant level with implementation of Section 401 Water Quality Certification requirements. The Section 401 Water Quality Certification would require implementation of BMPs (e.g., silt curtains) that would reduce water quality impacts associated with

construction of the cofferdam and water quality monitoring. Therefore, compliance with Section 401 Water Quality Certification requirements would ensure that **impacts related to the Proposed Project's potential alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on-site or off-site, would be less than significant; no mitigation is required.**

HYDRO-3. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site?

Land Side Construction Activities

Dewatering methods would be required at all times during construction, to promptly remove and dispose of all water from any source entering the Project Site. Since the amount and volume of dewatering is not known at this time, the Proposed Project could result in potentially significant impacts related to altering the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site. However, compliance with the General Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties (Order No. R4-2013-0095, NPDES No. CAG994004) would ensure that the Proposed Project would not result in flooding on-site or off-site during construction activities. In addition, the Proposed Project includes minimum construction BMPs included in the MS4 permit that ensure that surface runoff rates and amounts would not result in flooding to either on or off site areas. Therefore, compliance with General Waste Discharge Requirements for Discharges of Groundwater from Construction and Project Dewatering to Surface Waters in Coastal Watersheds of Los Angeles and Ventura Counties (Order No. R4-2013-0095, NPDES No. CAG994004), **would result in less than significant impacts. No mitigation measures are required**.

In-Water Construction Activities

Construction of the cofferdam could substantially alter the existing drainage pattern of the canal and as such, the Proposed Project could result in potentially significant impacts related to altering the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site. Alteration of the Grand Canal west bank and water flowing in the Grand Canal (tidal flow) would be diverted around the temporary cofferdam structure by the presence of the sheeting. A hydraulic analysis of the Grand Canal was performed to simulate the effects of the cofferdam and diversion structure obstructions during the construction phase of the Proposed Project. The cofferdam and diversion structure were modeled as blocked obstructions within the affected cross-sections of Grand Canal. The dimensions of the cofferdam are 95 feet in length by 23 feet wide, whereas the width of the Grand Canal in the vicinity ranges from approximately 65 to 70 feet. The existing and proposed conditions models were run with different flood conditions (dry, wet, extreme flood) to estimate the potential for water to overtop the banks of the Grand Canal and result in flooding. The model results indicate that although there are increases in starting water surface elevation for all three flood conditions, the flow would be contained within the channel banks for all flood conditions. As such, there would be no adverse impact to the Grand

Canal for rainfall events up to and including the 100-year, 24-hour storm event during the temporary construction of the cofferdam.

Based on the analysis above, construction of the temporary cofferdam would not substantially alter the existing drainage patterns or hydrology of the Grand Canal or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site and therefore**, impacts would be less than significant; no mitigation is required.**

HYRDO-4. Would the project create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

For both land side and in-water construction activities, no runoff impacts that would exceed the capacity of existing or planned stormwater drainage systems would occur during construction since the Proposed Project would include construction BMPs identified in the MS4 Permit. In addition, during construction, the off-site storm drain system at Hurricane Street and the laydown areas would be protected in place and construction BMPs would prevent any construction pollutants from entering the Grand Canal, Ballona Lagoon or Ballona Creek. Therefore, construction activities associated with the Proposed Project would not create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems nor would they provide substantial additional sources of polluted runoff. As such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-5. Would the project otherwise substantially degrade water quality?

As previously shown in Table 3.7-1, sediment toxicity, exotic vegetation, habitat alterations, hydromodification, reduced tidal flush, trash and other metals and hydrocarbons are listed as 303(d) impairments in Ballona Lagoon and Marina del Rey Harbor. Both land side and in-water construction activities could result in a discharge of contaminated sediments, removed vegetation, trash, and other metals and hydrocarbons. In addition, although no known contaminated sediments are located at the Project Site, excavated soils may become accidentally contaminated in the event of a construction-related spill and could enter the Grand Canal, Ballona Lagoon, and Ballona Creek (associated with Laydown Area 3 in Culver City). Combined, these activities and events could result in a potentially significant impact related to degraded water quality. However, the minimum construction BMPs identified in the MS4 Permit include a Spill Prevention and Control BMP in order to promptly contain and clean up spills, along with a Stockpile Management BMP to protect soil piles in place. As a result, there is a low risk of soil contamination from spills. To the extent feasible, native vegetative would be protected in place (only a portion of the west bank of the Grand Canal would be temporarily affected [see Figure 2-2 in Chapter 2, Project Description of this EIR]), which is a minimum construction BMP identified in the MS4 Permit. Vegetation that is removed would be managed according to the Solid Waste Management BMP to prevent the discharge of vegetation and trash from the Project Site into the adjacent waters. While t a cofferdam will be used to allow construction work to occur within the canal, the cofferdam would not result in reduced tidal flush, as flows would continue to pass around the cofferdam while in place (see discussion above). Therefore, construction of the Proposed Project would not otherwise substantially degrade water quality and as such, **impacts would be less than significant; no mitigation measures are required.**

HYDRO-6. Would the project place within a 100-year flood hazard area structures that would impede or redirect floodflows?

The Proposed Project is not located in a 0.1% flood hazard zone. Moreover, the hydraulic analysis performed to assess the flood risk of the temporary cofferdam in the Grand Canal determined that its construction would not impede or redirect flows or result in on- or off-site flooding. Therefore, the Proposed Project would not place within a 100-year flood hazard area structures that would impede or redirect floodflows and as such, **impacts would be less than significant; no mitigation measures are required.**

HYDRO-7. Would the project contribute to inundation by seiche, tsunami, sea level rise or mudflow?

The Proposed Project is not located in an area subject to mudflow and therefore, **no impacts would result and no mitigation measures are required**.

The Project Site is located in a designated tsunami hazard zone and therefore, construction workers, employees and visitors would currently be subject to this hazard. Low-lying coastal areas, harbor inlets, and the mouths of moderate-sized drainages are locations particularly at risk to the hazard of tsunami wave runup. Tsunami safety depends on numerous factors including the degree of the tsunami-hazardous zone urbanization, probability and extent of secondary disasters, readiness of the tsunami-hazardous zone for the emergency, etc. While Los Angeles has not experienced a major tsunami, a tsunami warning was issued for the coastline beaches in 2009 following the Samoan earthquake, in 2010 following the Chilean earthquake, and in 2011 following the earthquake in Japan (City of Los Angeles, 2016). The City of Los Angeles adopted the Tsunami Response Plan to address a tsunami evacuation response. If a tsunami evacuation is ordered, all City Emergency Operations Organizations (EOO) departments would be involved in support role activities and the City's Emergency Operations Center (EOC) would be activated at Level III, the highest level possible. In addition, when the City's EOC is activated, the County EOC and the Regional EOC is activated.

Since construction activities related to the Proposed Project would not contribute to inundation by tsunami given that this phenomena is generated by seismic activities or underwater landslides**, impacts would be less than significant; no mitigation measures are required.**

Risks associated with seiche within the Grand Canal or Ballona Lagoon would be dependent on a seismic event capable of displacing surface waters and resulting in subsequent flooding. Construction activities related to the Proposed Project would not contribute to this condition since seismic activity is the principle cause of this phenomena and therefore, **impacts would be less than significant; and no mitigation measures are required**.

State guidance projections for sea level rise to range from .13 feet at the lowest projection to 5.48 ft for the highest projection by the year 2100. Construction activities related to the Proposed Project are not anticipated to contribute to inundation caused by sea level rise (or storm-related flooding combined with sea level rise conditions) since these conditions are expected to occur after the anticipated two year construction period. Since the Proposed Project would not contribute to sea level rise given that this phenomenon is generated by climate change and global warming and will occur after the Proposed Project construction duration, **impacts would be less than significant and no mitigation measures are required.**

In December 2015, the California Supreme Court held in California Building Industry Association v. Bay Area Air Quality Management District, Case No. S213478, that CEQA generally does not require an analysis of how existing environmental conditions will affect a project's future users or residents and noted that CEQA may not require an analysis of the impacts of global warming, including sea level rise, on the project. However, as CEQA case law is in this area is continuing to evolve and State, regional and local efforts increase to understand the potential impacts climate change and sea level rise may have on public infrastructure , the City has decided to begin to address these issues.

HYDRO-8. Constitute a geologic hazard to other properties by causing or accelerating instability from erosion?

Impacts from erosion or siltation were previously described above and were determined to be less than significant. As noted above, compliance with existing regulatory requirements, including the MS4 Permit would mitigate these impacts. Therefore, the Proposed Project would not constitute a geologic hazard to other properties by causing or accelerating instability from erosion and as such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-9. Accelerate natural processes of wind and water erosion and sedimentation, resulting in sediment runoff or deposition that would not be contained or controlled on-site?

Impacts from erosion or siltation were previously described above and were determined to be less than significant. As noted above, compliance with existing regulatory requirements, including the MS4 Permit would mitigate these impacts. Therefore, the Proposed Project would not accelerate natural processes of wind and water erosion and sedimentation, resulting in sediment runoff or deposition that would not be contained or controlled on-site and as such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-10. Discharges associated with the project would create pollution, contamination or nuisance as defined in Section 13050 of the California Water Code (CWC) or that cause regulatory standards to be violated, as defined in the applicable NPDES stormwater permit or Water Quality Control Plan for the receiving water body.

Excessive erosion and sedimentation during construction are the most visible water quality impacts due to construction activities, as discussed in detail above. Other less visible water quality impacts are associated with discharge of pollutants such as metals, nutrients, soil additives, pesticides, construction chemicals, and other construction waste. No other pollutant discharges are anticipated from construction activities. Impacts to water quality were previously described above and determined to be less than significant with adherence to standard BMPs. Therefore, compliance with existing regulatory requirements, such as implementation of erosion and sediment control BMPs as required by the MS4 Permit would reduce discharges associated with project construction that would create pollution, contamination, or nuisance. As such, discharges associated with the project would not create pollution, contamination or nuisance as defined in Section 13050 of the California Water Code (CWC) or that cause regulatory standards to be violated, as defined in the applicable NPDES stormwater permit or Water Quality Control Plan for the receiving water body and therefore, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-11. Cause flooding during the projected 50-year developed storm event, which would have the potential to harm people or damage property or sensitive biological resources?

Impacts from flooding during the projected 50-year developed storm event area during construction were previously described above and were determined to be less than significant. In addition, a

hydraulic analysis of the Grand Canal was performed to simulate the effects of the cofferdam and diversion structure obstructions during the construction phase of the project and under various storm-event conditions (e.g., 100-year, 24-hour event). The results of the analysis determined that impacts would be less than significant and no mitigation was required. In addition, the analysis contained in Section 3.3, Biological Resources of this EIR determined that impacts related to biological resources would be less than significant with adherence to permit requirements and associated mitigation measures. Therefore, the Proposed Project would not cause flooding during the projected 50-year developed storm event, which would have the potential to harm people or damage property or sensitive biological resources and as such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-12. Substantially reduce or increase the amount of surface water in a water body?

As described above, construction of the cofferdam would temporarily increase the amount of surface water in Grand Canal. However, the hydraulic analysis of the Grand Canal concluded there was sufficient freeboard in the canal to support the 100-year, 24-hour storm event during the temporary construction of the cofferdam and that impacts would be less than significant. Therefore, the Proposed Project would not substantially reduce or increase the amount of surface water in a water body and as such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-13. Result in a permanent, adverse change to the movement of surface water sufficient to produce a substantial change in the current or direction of water flow?

As previously discussed above, construction activities would require temporary installation of a cofferdam in the Grand Canal to construct the diversion structure. However, the hydraulic analysis determined that the cofferdam would not result in a change to the movement of surface water nor would it produce a change in the current or direction of water flow and impacts would be less than significant. Therefore, the Proposed Project would not result in a permanent, adverse change to the movement of surface water sufficient to produce a substantial change in the current or direction of water flow and as such, impacts would be **less than significant; no mitigation measures are required.**

3.7.3.6 Operational Impacts

The analysis below describes the temporary and permanent impacts on hydrology and water quality anticipated as a result of the Proposed Project during operation. Operational activities with the potential to affect hydrology and water quality would generally include:

- Changes to, or interruptions in, the local drainage infrastructure as a result of the design potentially leading to localized or regional flooding or loss of groundwater recharge;
- Increases in directly connected impervious surface area as a result of the project leading to increases in the timing, rate, and/or volume of stormwater runoff, and, accordingly, flooding or erosion;
- Creation of substantial new sources of pollutants leading to new sources of contaminated runoff;
- Location of facilities within a designated floodplain or levee or dam failure inundation zone, exposing people and/or property to risks related to flooding, as well as effects resulting in changes in the location and direction of flood flows; or

- Location of facilities below the naturally occurring water table, with potential effects related to flooding of facilities, changes in groundwater quality and/or quantity, and new discharge of groundwater to surface water.

HYDRO-1. Would the project violate any water quality standards or waste discharge requirements?

Once the VAPP is constructed, the Project Site would be covered with up to 75% impervious cover with Public Facility uses and construction Laydown Area 1 would be covered with up to 81.2% impervious surfaces associated with parking for the VAPP Project Site and proposed Open Space. Public facilities generate pollutants that could impair water quality if not treated prior to discharge. Typical pollutants associated with public uses include but are not limited to suspended solids, total phosphorus, total nitrogen, total kjedahl nitrogen, copper, lead and zinc. The increase in impervious cover associated with the Project Site would increase the volume of runoff during a storm, which would more effectively transport pollutants generated during operation into receiving waters. Therefore, the Proposed Project could result in potentially significant impacts related to a violation of water quality standards or waste discharge requirements.

The Proposed Project includes LID features, Source Control and Treatment Control BMPs to reduce the discharge of pollutants. Treatment Control BMPs would also be incorporated into the design of on-site storm drain systems to treat runoff in accordance with the SUSMP standards, as required by the City. The Proposed Project would also include non-structural BMPs such as: storm drain stenciling and signage, properly designed outdoor materials storage areas, properly designed trash storage areas, proof of on-going BMP maintenance, and other items relevant to operations of the site. Implementation of site-specific source control and treatment control BMPs along with non-structural BMPs, in accordance with the SUSMP standards, would filter potential pollutants from runoff prior to discharge into receiving waters.

The most significant water quality benefit of LID is removal of stormwater runoff from the storm drain system or receiving waters. The first flush of stormwater runoff during a rainfall event typically contains higher concentrations of pollutants than later rainfall. By directing this runoff through LID features and providing retention, infiltration into the various layers of the LID feature and/or the native soils below the LID, and evapotranspiration, the pollutants do not reach the receiving body of water. Other pollutant removal processes achieved through LID include physical, chemical, and biological processes. Physical processes include filtering of sediment and pollutants, such as metals absorbed to the sediment. Degradation of fecal coliform bacteria also occurs by drying out and exposure to ultraviolet (UV) light from sun exposure. Biological processes include bioremediation and biodegradation. Phytoremediation, or pollutant removal by plants, includes pollutant uptake into and bioaccumulation within the plants, release of some pollutants from plants into the atmosphere, and breakdown of pollutants at the soil-plant root interface.

A water quality analysis of the Proposed Project was conducted to estimate the potential contribution of pollutants generated on the VAPP Project Site after implementation of source control and treatment control BMPs. Both the two-year design storm event and the 36-year continuous simulation modeling runs were used. Table 3.7-6 lists the Pre-Project and Post-Project Event Mean Concentration (EMC) for each pollutant modeled in the water quality analysis. As shown in Table 3.7-6, as a result of the Proposed Project, the various industrial pollutants increase. LID features under consideration include lined bioretention, planter box, and vegetated swale. The lined

bioretention, planter box, and vegetated swale are not effective alone in reducing fecal coliform and chemical oxygen demand (COD) contributions. As shown in Table 3.7-7 below, the vegetated swale does not perform to the maximum extent practicable and as such is not considered a viable option for this site. The lined bioretention or the planter box both have high pollutant removal efficiencies for most of the pollutants except COD, which shows a 40% reduction. In addition, while the lined bioretention or the planter box may have high pollutant removal efficiencies for fecal coliform, the discharge concentration would still be much higher in the developed condition compared to existing conditions. In order to reduce the discharge of pollutants to the maximum extent practicable, as required by the MS4 Permit, a treatment train or multiple BMPs are necessary.

Table 3.7-6. Pre-Project and Post-Project Event Mean Concentration Values for Project Site

	Pre-Project (Vacant)	Post-Project (Industrial)
Pollutant	EMC	EMC
TSS (mg/L)	164.7	229.4
COD (mg/L)	40.0	65.0
Total Copper (µg/l)	9.1	31.0
Total Lead (µg/l)	30.0	114.0
Total Zinc (µg/l)	38.8	565.6
Fecal Coliform (MPN/100 L)	2,174.8	653,070.4
Source: Hydrology Technical Memorandum, Watearth, August 2016.		

Table 3.7-7. Pollutant Removal by Various Biofiltration Practices

	% Removal		
Pollutant	Lined Bioretention	Planter Box	Vegetated Swale
Total Suspended Solids (TSS)	85	85	52
Chemical Oxygen Demand (COD)	40	40	40
Total Copper	66	66	26
Total Lead	63	63	13
Total Zinc	68	68	38
Fecal Coliform	81	81	30
Source: Hydrology Technical Memorandum, Watearth, August 2016.			

In order to further reduce the COD and fecal coliform concentrations from the site, a pre-treatment BMP is recommended. The water quality analysis modeled adding a vegetated filter strip as a pre-treatment BMP; results indicated the filter strip would further reduce the COD and fecal coliform concentrations from the site and any remaining pollutants. In addition, consistent with LID requirements, all impervious cover on the Project Site would be routed to drain through the vegetated filter strip by overland flow. Use of this pre-treatment BMP would also concentrate removal of sediment and other maintenance activities pollutants outside of the primary BMP. Applicable BMPs would be implemented in accordance with Los Angeles County NPDES MS4 Permit and associated SUSMP requirements, as required per Order R4-2012-0175. Therefore, with the implementation of these requirements the Proposed Project would not violate any water quality

standards or waste discharge requirements and as such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-2. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on-site or off-site?

Once the VAPP is constructed, the Project Site would be covered with up to 75% impervious cover and construction of Laydown Area 1 would be covered with up to 81.2% impervious surfaces. Implementation of the Project would alter the existing drainage pattern of the site, and increase peak flows and runoff volumes, resulting in increased erosion or siltation on-site or off-site and therefore, impacts are considered potentially significant. However, the increases in peak flows for the two-year, 10-year, and 100-year storm events would be managed through the use of LID features and MS4 drains. LID features under consideration include lined bioretention, planter box, and vegetated swale. LID features are required to retain 100-percent of the stormwater quality design volume (SWQDv) on-site through a combination of infiltration, evapotranspiration, and stormwater harvest and re-use unless it is demonstrated that it is technically infeasible to do so. The Proposed Project would implement a high removal efficiency biofiltration BMP within the Project Site sized to capture 1.5 times the runoff volume and to meet the minimum sizing requirements in the LID Manual. Therefore, the Proposed Project does not include changes to the existing storm drain system that would result in substantial erosion or siltation on site or off site. Thus, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-3. Would the project substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site?

Land Side Construction Activities

Once the VAPP is constructed, the Project Site would be covered with up to 75% impervious cover and construction Laydown Area 1 would be covered with up to 81.2% impervious surfaces. Implementation of the Proposed Project would alter the existing drainage pattern of the site, and increase peak flows and runoff volumes, resulting in increased flooding on-site or off-site and therefore, could result in potentially significant impacts. However, the increases in peak flows for the two-year, 10-year, and 100-year storm events would be managed through the use of LID features and MS4 drains. As shown in Table 3.7-8, proposed conditions peak discharges from the Project Site with implementation of the lined bioretention with underdrain are estimated at 72.8 cubic feet per second (cfs), 165.6 cfs, and 263.8 cfs for the two-year, 24-hour; ten-year, 24-hour; and 100-year, 24-hour design storm events, respectively. As shown in Table 3.7-8, the proposed two-year peak flow is 0.02 cfs, the existing ten-year peak flow is 0.05 cfs and the existing 100-year peak flow is 0.17 cfs. The proposed conditions peak flows in the Grand Canal with the implementation of the lined bioretention with underdrain are essentially no change from existing flows for the two-year, 24-hour; ten-year, 24-hour; and 100-year 24-hour events. The planter box and lined bioretention BMP option would also result in reduced peak flows from the site; 67-percent less than existing flows for the two-year, 24-hour event; seven-percent less for the ten-year, 24-hour event; and no change from the existing for the proposed 100-year, 24-hour event. (Watearth, 2016). As a result, the Proposed Project would not increase the rate or amount of surface runoff in a manner

that would result in flooding on-site or off-site and impacts would be **less than significant; no mitigation measures are required.**

Table 3.7-8. Proposed Peak Discharges and Flow

Proposed Conditions	2-year, 24-hour	10-year, 24-hour	100-year, 24-hour
Peak Discharges	72.8 cfs	165.6 cfs	263.8 cfs
Change from Existing	0	0	0
Peak Flow	0.02 cfs	0.05 cfs	0.17 cfs
Change from Existing	(0.04)	(0.09)	(0.07)

Source: Hydrology Technical Memorandum, Watearth, August 2016.

In-Water Construction Activities

Post construction, the diversion structure located in the Grand Canal would be below ground and would not protrude within the water column and as such, would not impede or redirect flows as demonstrated in the hydraulics analysis. Therefore, during operation, the Proposed Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on-site or off-site and as such, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-4. Would the project create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

Impacts to water quality and runoff during operation were previously described above and determined to be less than significant. The Proposed Project would use a high removal efficiency biofiltration BMP within the Proposed Project Site (located along the eastern side of the VAPP, adjacent to Esplanade) sized to capture 1.5 times the runoff volume and meeting the minimum sizing requirements in the LID Manual. The existing peak flows from the area contributing to the existing outfall at Hurricane Street would not increase due to the Proposed Project and pollutants would be reduced to the maximum extent practicable through the use of BMPs. Operational activities associated with the Proposed Project would not create or contribute runoff water that would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff during the operation phase. Consequently, operational activities are expected to result in **less than significant impacts on stormwater drainage capacity and polluted runoff**, **and no mitigation measures are required.**

HYDRO-5. Would the project otherwise substantially degrade water quality?

As previously shown in Table 3.7-1, sediment toxicity, exotic vegetation, habitat alterations, hydromodification, reduced tidal flush, trash, and other metals and hydrocarbons are listed as 303(d) impairments in Ballona Lagoon and Marina del Rey Harbor. During operation, the project would have the potential to discharge sediments, trash, and other metals and hydrocarbons. Typical pollutants associated with industrial uses include but are not limited to suspended solids, total phosphorus, total nitrogen, total kjedahl nitrogen, copper, lead, and zinc. The increase in impervious cover associated with the Project Site would increase the volume of runoff during a

storm, which would more effectively transport pollutants generated during operation into receiving waters and would be a potentially significant impact. However, the Project Site includes the required pervious surfaces (in the form of gravel and open space), which would accommodate the increased runoff (see analysis above) and would filter pollutants from water through a biofiltration BMP prior to discharge offsite. The BMPs under consideration include a lined bioretention with under drain or planter box, both with pre-treatment filter strips, which would remove the potential pollutants identified previously. Further, the gravel would serve to limit sediment erosion from the site. Operational activities associated with the Proposed Project would not otherwise substantially degrade water quality and therefore, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-6. Would the project place within a 100-year flood hazard area structures that would impede or redirect floodflows?

Impacts from placing structures within a 100-year flood hazard area during operation were previously described above and determined to be less than significant. As noted in the hydraulics analysis, the diversion structure would be installed in the Grand Canal, but would be entirely underground and would not protrude into the water column and therefore, would not impede or redirect floodflows. Therefore, the Proposed Project would not place within a 100-year flood hazard area structures that would impede or redirect floodflows and impacts would be **less than significant; no mitigation measures are required.**

HYDRO-7. Would the project contribute to inundation by seiche, tsunami, sea level rise or mudflow?

As previously discussed, the Proposed Project is currently located in a designated tsunami hazard zone and therefore employees and visitors would be subject to the risk of this hazard. Low-lying coastal areas, harbor inlets, and the mouths of moderate-sized drainages are locations particularly at risk to the hazard of tsunami wave run-up. Tsunami safety depends on numerous factors including the degree of the tsunami-hazardous zone urbanization, probability and extent of secondary disasters, readiness of the tsunami-hazardous zone for the emergency, etc. While Los Angeles has not experienced a major tsunami, a tsunami warning was issued for the coastline beaches in 2009 following the Samoan earthquake, in 2010 following the Chilean earthquake, and in 2011 following the earthquake in Japan (City of Los Angeles, 2016). The City of Los Angeles adopted a Tsunami Response Plan to address a tsunami evacuation response. If a tsunami evacuation is ordered, all City Emergency Operations Organizations (EOO) departments would be involved in support role activities and the City's Emergency Operations Center (EOC) would be activated at Level III, the highest level possible. In addition, when the City's EOC is activated, the County EOC and the Regional EOC is activated.

As discussed in Chapter 2, Project Description of this EIR, the existing VPP is the City's largest pumping plant, it and serves as a critical facility in the wastewater conveyance system receiving and conveying sewage from the communities of Topanga, Pacific Palisades, Brentwood, Santa Monica, Venice, Mar Vista, and parts of Los Angeles County. The control facility for the VPP is onsite, along with the wireless telemetry that controls the Marina and Washington Blvd. tide gates. The VPP receives wastewater from this tributary system via a Coastal Interceptor System (CIS) 48-inch force main, and continuously pumps the sewage flows to the Hyperion Treatment Plant. The Venice Dual Force Main, which will be construction by 2020, will augment and provide back-up conveyance capacity to Hyperion. The CIS runs parallel to the Grand Canal in the vicinity of the VPP. There is an

emergency sewer discharge pipe inside the Grand Canal through which in an emergency, sewage flows can be diverted to the Ballona Lagoon, a tidal channel on the Silver Strand Peninsula, that is connected through the Marina tide gate to the Pacific Ocean via the Marina del Rey Harbor.

In storm conditions, the VPP sewer system is affected by infiltration from storm drains and groundwater. Plant failure (possibly due to power outages from flooding) would lead to exceeded sewer capacity which would require emergency discharges and inundation into the Ballona Lagoon, the Grand Canal and the surrounding local streets. There have been several occasions when wet-weather flows have nearly exceeded the VPP pumping capacity resulting in near misses of wastewater spills into the Grand Canal and Ballona Lagoon. Locally, wastewater spills would affect human health and the environment, surrounding streets, as well as ESHA areas including the Ballona Lagoon and the Grand Canal.

The Sea Level Rise Vulnerability Study for the City of Los Angeles (Grifman et al. 2013), and the USEPA Los Angeles Sanitation Climate Resilience Evaluation and Awareness Tool (CREAT) Exercise Report for Wastewater Assets (USEPA, 2016) highlight two important issues related to City of Los Angeles sewers and wastewater pumping plants regarding climate change and sea level rise. First, wastewater pumping plants in the Venice Beach area are vulnerable to sea level rise because sea level rise conditions combined with 100-year storm surges could flood the wastewater pumping plants as shown in Figures 3.7-1 and 3.7-2, and cause electrical equipment to fail. Second, plant failures caused by flooding could contribute to inundation and result in wastewater spills with negative environmental consequences.

As discussed, the VPP and Proposed VAPP are also directly connected to the Pacific Ocean via Maria del Rey Harbor. A power outage as a result of inundation from storm surges and sea level rise conditions at the existing VPP and Proposed VAPP facility once constructed could result in wastewater releases into the Pacific Ocean. ,

Figure 3.7-1
Flood Risk to VAPP Due to Sea Level Rise and 100-Year Storm Surge
Venice Auxiliary Pumping Plant Project

Figure 3.7-1
Comparison of Flood Risk to VAPP Due to Sea Level Rise (SLR) and 100-Year Storm Surge at 0 cm, 50 cm, 100 cm, and 150 cm SLR Levels
Venice Auxiliary Pumping Plant Project

As shown in Figures 3.7-1 and 3.7-2, at a sea level rise of 50 cm (2050 to 2100), the Grand Canal and Ballona Lagoon which are adjacent to the VPP and proposed VAPP will inundate adjacent land areas during a 100-year flood event. Figure 3.7-1 shows that at a sea level rise level combined with a storm surge of 200 cm (16.6 ft), the existing VPP and the proposed VAPP and surrounding areas would likely be inundated during a 100-year storm event. The USEPA has projected a 50 cm (4.16 ft) rise in sea level in the Venice area by 2050 (based on NOAA estimates of 0.88mm/year sea level rise trends in the Los Angeles area) (USEPA, 2016). The California Coastal Commission estimates that sea level rise would range between 1.38 feet (42 cm) and 5.48 feet (167cm) by 2100.. Based on current observations, Los Angeles will likely be on the lower end of this range. While the Proposed Project may not be completely flooded during a 100-year storm event based on these projections, some part of the facilities and tide gates may be inundated. Should the Proposed Project fail or be nonfunctional due to local power outages, created by a storm event is causing flooding of the facilities, wastewater spills into the surrounding water bodies may occur as a result and contribute to the inundation . The Proposed Project and existing VPP could become completely inundated by sewage-contaminated water depending on the duration of the power outage. This could cause damage to the plant's electrical equipment and create local environmental and economic impacts.

The USEPA (2016) study of certain LA Sanitation wastewater assets identified potential measures that could reduce risks from climate change and sea level rise to LASAN facilities. Potential measures identified in the study include: installing temporary flood barriers, designing a wet weather plan specific to each installation, constructing perimeter walls, improving and protecting back-up power for pumping plant facilities, and using watertight enclosures to further protect electrical equipment, instrumentation and controls (USEPA, 2016).

In summary, due to its coastal location, the existing VPP and the Proposed VAPP are currently located in a tsunami hazard zone and are already vulnerable to inundation by tsunami impacts. Also, due to their location adjacent to tidal water bodies (i.e. the Pacific Ocean, Grand Canal and Ballona Lagoon), that could rise due to sea level rise and storm surges, the VPP and the Proposed VAPP are vulnerable to flooding from 100-year storm events. In the event of extended power outages during such a storm, this flooding could be exacerbated by any wastewater spills that might occur during operations due to any extended power outages. Therefore, the Proposed Project would contribute to inundation caused by tsunami and sea level rise during project operations, **and impacts are significant and unavoidable**.

In December 2015, the California Supreme Court held in California Building Industry Association v. Bay Area Air Quality Management District, Case No. S213478, that CEQA generally does not require an analysis of how existing environmental conditions will affect a project's future users or residents and noted that CEQA may not require an analysis of the impacts of global warming, including sea level rise, on the project. However, as CEQA case law is in this area is continuing to evolve and State, regional and local efforts increase to understand the potential impacts climate change and sea level rise may have on public infrastructure, the City has decided to begin to address these issues.

HYDRO-8. Constitute a geologic hazard to other properties by causing or accelerating instability from erosion?

Impacts from erosion or siltation were previously described above and were determined to be less than significant. Compliance with existing regulations would reduce the potential for causing or accelerating instability from erosion. Adherence to existing regulatory requirements, such as implementation of LID features, Source Control and Treatment Control BMPs would reduce the

impacts of the Proposed project related to causing or accelerating instability from erosion to **less than significant levels; no mitigation measures are required.**

HYDRO-9. Accelerate natural processes of wind and water erosion and sedimentation, resulting in sediment runoff or deposition that would not be contained or controlled on-site?

Impacts from erosion or siltation and runoff were previously described above and determined to be less than significant. Compliance with existing regulations would reduce the potential for sediment runoff or deposition that would not be contained or controlled on-site. Adherence with existing regulatory requirements, such as implementation of LID features, Source Control and Treatment Control BMPs would reduce impacts of the Proposed project related to accelerating natural processes of wind and water erosion and sedimentation to **less than significant levels; no mitigation measures are required.**

HYDRO-10. Discharges associated with the project would create pollution, contamination or nuisance as defined in Section 13050 of the California Water Code (CWC) (see definitions on page G.2-4 of the City's Thresholds) or that cause regulatory standards to be violated, as defined in the applicable NPDES stormwater permit or Water Quality Control Plan for the receiving water body.

Impacts to water quality were previously described above and determined to be less than significant. Compliance with existing regulatory requirements, such as implementation of LID features, Source Control and Treatment Control BMPs as required by the MS4 Permit would reduce discharges associated with project operation that would create pollution, contamination or nuisance as defined in Section 13050 of the CWC or that cause regulatory standards to be violated, as defined in the applicable NPDES stormwater permit or Water Quality Control Plan for the receiving water body to **less than significant levels; no mitigation measures are required.**

HYDRO-11. Cause flooding during the projected 50-year developed storm event, which would have the potential to harm people or damage property or sensitive biological resources?

Impacts from flooding during the projected 50-year developed storm event were previously described above and determined to be less than significant. The Proposed Project would not cause flooding during the projected 50-year developed storm event, which would have the potential to harm people or damage property or sensitive biological resources. A diversion structure would be installed in the Grand Canal for use during construction and would remain in place and be utilized post-construction. As noted in the hydraulics analysis, the diversion structure would be located under the Grand Canal and would not protrude into the water column and therefore, would not result in flooding. Therefore, impacts would be **less than significant; no mitigation measures are required.**

HYDRO-12. Substantially reduce or increase the amount of surface water in a water body?

Impacts to Grand Canal during operation were previously described above and were determined to be less than significant. Therefore, the Proposed Project would not substantially reduce or increase the amount of surface water in a water body; impacts would be **less than significant; no mitigation measures are required.**

HYDRO-13. Result in a permanent, adverse change to the movement of surface water sufficient to produce a substantial change in the current or direction of water flow?

Impacts to Grand Canal during operation were previously described above and determined to be less than significant. As noted in the hydraulics analysis, the diversion structure would be located under the Grand Canal and would not protrude into the water column and therefore, would not result in in permanent, adverse change to the movement of surface water sufficient to produce a substantial change in the current or direction of water flow. Impacts would be **less than significant; no mitigation measures are required.**

3.7.4 Mitigation Measures

The following mitigation measure will help address impacts to hydrology and water quality related to tsunami and sea level rise:

MM-HYDRO- 1: The City of Los Angeles Department of Sanitation shall prepare a Tsunami Response and Action Plan designed for the VPP/VAPP facility by 2020. At a minimum, the plan shall identify and implement specific measures related the VPP/VAPP which are designed to 1) reduce impacts to the facility in the event of a tsunami and/or with future sea level rise conditions and 2) identify what actions are needed at the VPP/VAPP facility and within the wastewater infrastructure system to accelerate the recovery period of the VPP/VAPP facility in the event that a tsunami or major storm event disabled the facilities. These measures shall be implemented at the VAPP by 2022. The action plan could include the following measures:

- Evaluate the potential for installing temporary flood barriers as needed when sufficient notice is given;
- Evaluate the use of watertight enclosures to further protect electrical equipment, instrumentation and controls before completing final design of the VAPP facility and other LA Sanitation wastewater facilities located within local coastal areas, as appropriate.

3.7.5 Significant Unavoidable Impacts

Project construction activities would not generate unavoidable adverse impacts to hydrology or water quality. Operation of the Proposed Project would contribute to inundation by tsunami or sea level rise, if a power failure resulted, and impacts to water quality would be significant and unavoidable.

3.7.6 Cumulative Impacts

The geographic scope for cumulative impacts on hydrology and water quality includes the Marina del Rey subwatershed. Implementation of the Proposed Project would include compliance with of all required laws, permits, ordinances and plans, such as the MS4 Permit, LID, SUSMP, and Construction General Permit requirements, that would reduce incremental effects to hydrology and water quality. The Proposed Project would not result in a substantial increase of impervious surfaces within the watershed and is required to include pervious surfaces to retain storm water drainage onsite. This increase in impervious surfaces with implementation of BMPs as required by the MS4 Permit would not lead to an increase in surface runoff or significant pollutant loadings. The areas surrounding the Proposed Project area are of similar urban pervious nature, and any future development would also

include compliance with of all required laws, permits, ordinances and plans, such as the MS4 Permit, LID, SUSMP, and Construction General Permit requirements in order to meet runoff requirements.

There are eight related projects surrounding the Project area that are also within the Marina del Rey subwatershed. These related projects generally consist of roadway improvements/repairs, stormwater and sewer infrastructure improvements, VPP generator improvements, and recreational development. The majority of these projects would occur within already developed areas and would not significantly contribute to increased runoff as result of increases in impervious surfaces. Other future developments within the urban and developed subwatershed would have similar effects as the Proposed Project. However, the past, current, and reasonably foreseeable future projects in the subwatershed would be required to implement similar measures when obtaining relevant permits, including compliance with the LID Manual and SUSMP requirements and implementation of minimum BMPs during construction. This would help reduce impacts to water quality and retain runoff, and to ensure that the incremental effects of individual projects do not cause a substantial cumulative impact related to water quality. For example, during operation, projects would be required to maintain water quality through development and implementation of LID BMPs.

Overall, potential impacts to hydrology and water quality associated with future development in the watershed and the region would not be cumulatively considerable with compliance with all applicable laws, permits, ordinances, and plans. As a result, potential impacts to hydrology and water quality from the Proposed Project in combination with the related projects would be less than cumulatively considerable.

3.8 Land Use and Planning

This section describes the affected environment and regulatory setting for land uses and planning related to the Project Site and surrounding area. It also describes the potential land use and planning impacts that would result from implementation of the Venice Auxiliary Pumping Plant (VAPP or Proposed Project). As noted in the analysis below, direct impacts associated with land use and planning during construction or operation of the Proposed Project would be less than significant and no mitigation measures are required. However, the Proposed Project would result in significant and unavoidable secondary impacts on surrounding land uses, related to construction noise and vibration, even with mitigation incorporated.

3.8.1 Regulatory Setting

3.8.1.1 California Coastal Act of 1976

The Coastal Act was enacted in 1976 by the California legislature, which established it as the primary law that governs the decisions of the California Coastal Commission (Commission). It was created in 1972 through the California Coastal Conservation Initiative and Proposition 20. The Coastal Act outlines standards for development within the Coastal Zone that seek to balance the right to develop with strong environmental policies aimed to protect coastal resources. The Coastal Zone is a distinct and valuable natural resource of vital and enduring interest to all the people and exists as a delicately balanced ecosystem. It encompasses 1.5 million acres of land and is bounded by the ocean on the west and an inland easterly boundary that traverses along the entire California coast.

The State of California's basic goals for the Coastal Zone are to (a) protect, maintain, and, where feasible, enhance and restore the overall quality of the coastal zone environment and its natural and artificial resources; (b) assure orderly, balanced utilization and conservation of coastal zone resources taking into account the social and economic needs of the people of the state; (c) maximize public access to and along the coast and maximize public recreational opportunities in the coastal zone consistent with sound resources conservation principles and constitutionally protected rights of private property owners; (d) assure priority for coastal-dependent and coastal-related development over other development on the coast; (e) encourage state and local initiatives and cooperation in preparing procedures to implement coordinated planning and development for mutually beneficial uses, including educational uses, in the coastal zone.

The Coastal Act is designed to empower local governments to create Local Coastal Programs (LCPs) as land use policy to govern decisions that determine the conservation and the best use of coastal resources. LCP's are usually incorporated into a city's general plan for areas within that jurisdiction's Coastal Zone. Until the Coastal Commission certifies an LCP, the Commission makes the final decisions on all development within a city within the Coastal Zone and has appellate authority. Chapter 3 of the Coastal Act includes the standards used by the Commission in the review of coastal development permits and LCPs. It governs all development along the Coast and mandates protection of public access, recreational opportunities, and marine and land resources.

Venice Coastal Zone

The Venice Coastal Zone is within the California Coastal Zone and is generally bounded by Marine Street on the north; the city/county boundary, Washington Boulevard and Via Marina on the south; Lincoln Boulevard and Via Dolce on the east; and the Pacific Ocean on the west.

3.8.1.2 City of Los Angeles General Plan

A general plan is required by the State of California to address the specified provisions of seven mandated elements land use, circulation, housing, conservation, open space, noise, and safety—to the extent that the provisions are locally relevant. The City of Los Angeles General Plan contains eleven elements, including a Framework, Air Quality, Health, and Service Systems/Public Recreation. Instead of a Circulation Element, the City of Los Angeles has a Mobility Element.

The City of Los Angeles General Plan is a comprehensive, long-term declaration of purposes, policies, and programs for the development of the city. It provides land use policies that meet the existing and future needs and desires of the community.

General Plan Framework Element

The General Plan Framework Element (GPFE) is a strategy for long-term growth that sets a citywide context to guide subsequent amendments to the City's community plans, zoning ordinances, and other pertinent programs. The GPFE responds to state and federal mandates to plan for the city's future. An Environmental Impact Report (EIR) that analyzes the GPFE and it's consistency with the California Environmental Quality Act (CEQA) was also prepared.

The Residential Citywide Design Guidelines (RCDG) are part of the City's GPFE and serve to implement the City's 10 Urban Design Principles (see Table 3.8-1). The RCDG do not supersede regulations in the Los Angeles Municipal Code (see discussion below). They contain options, solutions, and techniques to achieve the goal of excellence in new design. Through the Department of City Planning's Urban Design Studio and the Development Services Center, the RCDG and the 10 Urban Design Principles function as a design program for the City that helps communicate design expectations to applicants during the design phase of their projects. They facilitate the application of design objectives and encourages high-quality development that is appropriate to the context of the city's climate and urban environment. The 10 Urban Design Principles are a statement of the City's vision for the future of Los Angeles, providing guidance for new development and encouraging projects to complement existing urban form in order to enhance Los Angeles' built environment. The 10 Urban Design Principles are intended to apply to a variety of urban forms that exist within Los Angeles, from the most dense and concentrated city centers to suburban areas.

Land Use Element

The Land Use Element includes Community Plans that establish policy and standards for each of the 35 geographic areas in the city. Each community plan is focused on specific geographic areas of the city and, therefore, include more specific policies and programs than those developed for the city as a whole.

Community Plans are intended to promote an arrangement of land uses, streets, and services that will encourage and contribute to the economic, social and physical health, safety, welfare, and convenience of the people who live and work in the community. The Community Plans also guide

Table 3.8-1. The 10 Principles of Urban Design

1.	Develop inviting and accessible transit areas.
2.	Reinforce walkability, bikeability and well-being.
3.	Nurture neighborhood character.
4.	Bridge the past and the future.
5.	Produce great green streets.
6.	Generate public open space.
7.	Stimulate sustainability and innovation in our city.
8.	Improve equity and opportunity.
9.	Emphasize early integration, simple processes and maintainable solutions.
10.	Ensure connections.

Source: City of Los Angeles, 2009.

development by establishing the City's goals, policies, and development standards with the objective of creating a healthy and pleasant environment. Goals, objectives, policies, and programs are created to meet the existing and future needs of the community through 2010. The Community Plans are intended to coordinate development among the various parts of the city of Los Angeles and adjacent municipalities in a fashion both beneficial and desirable to the residents of their communities and compatible with infrastructure and public services. The City is currently in the process of updating a number of community plans.

Safety Element

Planning and preparedness are critical in mitigating the extent of the impacts of a disaster, through pre-disaster abatement, pre-disaster response preparation and post-disaster recovery plans. The state identifies local safety elements as key tools for assisting local jurisdictions in organizing their hazard mitigation, disaster response, and recovery efforts. The Safety Element of the City of Los Angeles General Plan provides a contextual framework and overview of the city's natural hazards (fire, flood, earthquake, landslides, and other hazards), hazard mitigation, and emergency response operations. The Safety Element also contains goals, objectives, policies, and City Emergency Operations Organization (EOO) programs.

To further address issues concerning seismic safety and resilience, the Mayoral Seismic Safety Task Force recently undertook an evaluation of buildings and water systems and telecommunication infrastructure. Their findings and recommendations are presented in the City of Los Angeles' Resilience by Design report. The intent of the report is to identify ways to protect residents' lives and the economy, improve response to earthquakes, and prepare for quick recovery from earthquakes.

Conservation Element

State law intends that conservation elements address "conservation, development, and utilization of natural resources including water and hydraulic force, forests, soils, rivers and other waters, harbors, fisheries, wildlife, minerals, and other natural resources." State general plan legislation was amended (1995) to require that preparation of the water portion of the general plan address water and land reclamation, water (including ocean) pollution, regulation and use of land in stream beds, erosion, watershed protection, flood control and rock, sand and gravel resources.

The Conservation Element of the City of Los Angeles General Plan surveys laws, requirements, and procedures that have been established for the protection of natural resources. It primarily is an informational document, which is designed to help readers understand the context, history, and opportunities for protection and improvement of the city's natural resources.

Open Space Element

The Open Space Element of the City of Los Angeles General Plan provides information to guide city citizens and decision makers with the identification, preservation, conservation, and acquisition of open space in the city of Los Angeles. The Open Space Plan includes the regulation of publically owned land as well as privately owned land for the public's benefit and protection from land misuse.

Plan for a Healthy Los Angeles

The Plan for a Healthy Los Angeles (Plan) is a new Health and Wellness Element of the City's General Plan. It focuses on public health and safety to address basic quality-of-life issues, including safe neighborhoods and healthy foods, which will help the City of Los Angeles achieve better health and social equity. In the Plan, existing health-oriented policies are promoted while new policies are created to make Los Angeles a healthier place to live, work and play.

Mobility Element

The Mobility Element of the General Plan (Mobility Plan 2035) was updated in 2015. The Mobility Plan 2035 provides the policy foundation for achieving a transportation system that balances the needs of all road users. As an update to the City's General Plan Transportation Element (last adopted in 1999), Mobility Plan 2035 incorporates "complete streets" principles and lays the policy foundation for how future generations interact with the streets in Los Angeles. The California legislature adopted AB 1358 in 2008, *The Complete Streets Act*, which requires local jurisdictions to "plan for a balanced, multimodal transportation network that meets the needs of all users of streets, roads, and highways, defined to include motorists, pedestrians, bicyclists, children, persons with disabilities, seniors, movers of commercial goods, and users of public transportation, in a manner that is suitable to the rural, suburban or urban context."

Complete streets are designed and operated to enable safe access for all users, including pedestrians, bicyclists, motorists, and transit riders. Some public benefits include improved transportation, a cleaner environment, and healthier neighborhoods. Complete streets offer safety, comfort, and convenience for all users. It enhances mobility and active transportation through multi modal connectivity and providing people the ability to utilize the public space to exercise, work, engage in community activities, interact with their neighbors, and beautify their surroundings. The City's transportation system will continue to evolve to fit the context of the time and situation.

Mobility Plan 2035 includes goals that define the City's high-level mobility priorities. Each of the goals contains objectives that are targets used to help measure the progress of the Plan and policies, broad strategies that guide the City's achievement of the Plan's five goals: (1) Safety First, (2) World Class Infrastructure (3) Access for All Angelenos (4) Collaboration, Communication and Informed Choices, and (5) Clean Environments & Healthy Communities.

The purpose of Mobility Plan 2035 is to present a guide to the further development of a citywide transportation system that provides for the efficient movement of people and goods. Mobility Plan 2035 recognizes that primary emphasis must be placed on maximizing the efficiency of existing and

proposed transportation infrastructure through advanced transportation technology, through reduction of vehicle trips, and through focusing growth in proximity to public transit. In addition, the Plan sets forth street designations and related standards. A listing of street types with descriptions and generalized cross sections for each designation is included in the *Complete Street Design Guide*. Mobility Plan 2035 recognizes the contribution of a proper mix of land uses to reduce vehicle trips. Uses that better serve the needs of the population closer to where they work and live reduces the number and distance of vehicle trips and decreases the amount of pollution from mobile sources.

Air Quality Element

The City's Air Quality Element accounts for economic and social growth and goals while achieving National and State Ambient Air Quality Standards. The Air Quality Element intends to keep population and economic growth in check to reduce environmental degradation and maintain a balance of urban systems with citywide elements, community plans, and neighborhood plans.

Noise Element

The Noise Element references the City's noise standards to address noise sources, mitigation strategies, and management programs. The Element also addresses the different federal, state, and City jurisdiction as it relates to automotive, aircraft, and nuisance noise. While regulation of vehicular noise is outside of a City's control, regulating land use, implementing federal and state regulations, and enforcing nuisance noise are within a city's authority and therefore, discussed in the Noise Element.

Service Systems/Public Recreation Element

The Public Recreation Plan emphasizes neighborhood and community recreational sites and parks. It includes policies and programs to meet the needs for community buildings, swimming pools, and tennis courts. The objectives for the Public Recreation Plan are based on recognized planning principles and the extent and nature of deficiencies in the City's recreational facilities and are as follows: (1) To provide a guide for the orderly development of the City's public recreational facilities, (2) To provide long-range standards for use in connection with new subdivisions, intensification of exiting residential development or redevelopment of blighted residential areas as described under general local recreation standards, (3) To develop and locate public facilities to provide the greatest benefit to the greatest number of people at the least cost and with the least environmental impact, (4) To provide a guide of priorities for the acquisition and development of public recreational facilities; and (5) To further refine and carry out the goals and objectives set forth in the Concept and Citywide Plan for recreation.[1]

3.8.1.3 City of Los Angeles Administrative Code

The City of Los Angeles Administrative Code is used to assist City offices, departments, and other governmental agencies with their functions, and serves as the official source for information about ordinances enacted by the City of Los Angeles that regulate administrative processes.

[1] Source: http://planning.lacity.org/Code_Studies/GeneralElement/PublicRecreationPlan.pdf. Accessed August 25, 2016.

Section 19.85 Public Works Improvements Arts Program

The mission of the City of Los Angeles Public Works Improvements Arts Program ("Program") is to:

> Provide publicly accessible works of art, arts and cultural facilities, and services for the cultural benefit of the city, its citizens and its visitors.

The Program was established to connect all City capital improvement projects with the opportunity to create art installed at facilities, enhance amenities, assist with the restoration of historic features, and provide community art services throughout the city. The Program is managed by the Department of Cultural Affairs (DCA) and it's General Manager.

The goals of the Program are:

- To provide appropriate forms of artistic and cultural expression in all City capital improvement projects;
- To integrate the work of artists into the design and planning of capital improvement projects;
- To ensure that the selected art programs serve the needs of the people using the capital improvement projects;
- To ensure that qualified artists of all genders and ethnic groups are represented;
- To provide a variety of arts and cultural activities; and
- To ensure the highest of level of artistic excellence.

All City capital improvement projects, whether funded by Council controlled or proprietary departments, must comply with this Program. The funds can be used for projects in many different ways. There is a formal consultation process that the sponsoring agency must go through that is determined by the Department of Cultural Affairs. Inter-agency consultations initiate the process.

All public art projects are reviewed by the Public Art Committee and recommended for approval by the Cultural Affairs Commission.

According to the Department of Cultural Affairs, the approval process consists of 1) completing the Application for Approval of Public Artwork, and gathering requested supporting materials; 2) submitting an application to the Public Art Division; 3) scheduling dates to present the art project to the Public Art Committee and Cultural Affairs Commission; 4) appearing before the Public Art Committee to receive feedback and be recommended for approval to the Cultural Affairs Commission; and 5) appearing before the Cultural Affairs Commission to receive a conceptual and/or final approval.[2]

There is an option for an Exemption to this Section of the LAMC that allows for Public Works Projects to pay the 1% of the total project budget to the Department of Cultural Affairs, in lieu of using the funds for public art on the Project Site.

3.8.1.4 City of Los Angeles Municipal Code

The City of Los Angeles Municipal Code (LAMC) includes standards for different land uses and identifies land uses that are allowed in various zoning districts. Specifically, it consolidates and coordinates all existing zoning regulations and provisions in order to designate, regulate, and restrict locations and land uses.

Section 12.09.5 "RW2" Residential Waterways Zone

Section 12.09.5 of the LAMC is the "RW2" Residential Waterways Zone established by Ordinance No. 138,095. It established regulations that make possible the utilization of certain lots fronting on navigable public canals or waterways, or separated therefrom only by a public street, which make up, or are a portion of, a sizable system of recreational waterways when such lots are predominantly those which were recorded prior to June 1, 1946.

Because of exceptional past history, present conditions, the proximity of such lots to recreational water areas, and their usual location in areas which enjoy optimum climatic conditions, the best development of the property may require variation from some of the standard housing requirements necessary or desirable to the rest of the city.

Section 99.00 Los Angeles Green Building Code

Section 99 of the LAMC is the Los Angeles Green Building Code (LAGBC) and adopts by reference the California Green Building Standards Code (CAL Green Code). This code applies to the construction of all new buildings, all building alterations with a building permit valuation of over $200,000, and all building additions. This includes construction, alteration, replacement, repair, use and occupancy, and demolition of all structures connected to applicable buildings.

Venice Local Coastal Program

Section 30500 of the California Coastal Act establishes that Local Coastal Programs (LCP) govern decisions that determine the short- and long-term conservation and protection of coastal resources. A LCP specifies appropriate location, type, and scale of new or changed uses of land and water within the California Coastal Zone and also addresses planning and land use conformity with Coastal Act goals and policies. A Venice LCP was created to serve as a basic planning tool used by the City of Los Angeles to guide development in the Venice Coastal Zone, in partnership with the Coastal Commission. The Venice LCP was intended to contain the policies for future development and protection of coastal resources in the community of Venice.

The Venice LCP was adopted by the Los Angeles City Council and then was submitted to the Coastal Commission for their review for consistency with Coastal Act requirements. The Venice LCP included a Venice LCP Land Use Plan and the Venice Specific Plan to implement the plan. Both documents are used locally by the City of Los Angeles Department of City Planning to regulate development within the Venice Coastal Zone. Per the CA Coastal Act, a Venice Local Coastal Program (LCP) was presented to the California Coastal Commission in 2001. The Venice Land Use Plan was certified but the Venice Implementing Ordinance (Venice Specific Plan) was ultimately not certified. As a result, determinations for Coastal Development Permits (CDPs) are split, with applicants within the Dual Jurisdiction Zone processing their case through both the City of Los Angeles and the CA Coastal Commission while applicants within the Single Jurisdiction Zone were allowed to choose whether to process their case through the City of Los Angeles or the CA Coastal Commission. Currently, the City of Los Angeles does not have a certified Local Coastal Program for the Venice Coastal Zone.

Venice Coastal Zone Specific Plan (Venice Specific Plan)

Ordinance No. 172,897 established the Venice Specific Plan and created eight sub-areas within the Venice community. The Venice Specific Plan is intended to comply with the California Coastal Act of 1976 for development within the Venice Coastal Zone. The purpose of the Venice Specific Plan is to implement the policies and goals of the California Coastal Act and to address the unique conditions within the Venice Coastal Zone that must be consistent with the Los Angeles General Plan. It regulates all development, including use, height, density, setback, buffer zone, and other factors in order that it be compatible in character with the existing community and to provide for the consideration of aesthetics and scenic preservation and enhancement, and to protect environmentally sensitive areas.

Venice Local Coastal Program Land Use Plan

The Venice Local Coastal Program Land Use Plan (Venice LCP-LUP) is intended to serve as the Local Land Use Plan of the Venice LCP. It was prepared to comply with the California Coastal Act of 1976 for development within the Venice Coastal Zone and was certified by the California Coastal Commission in June 2001. The purpose of the Venice LCP-LUP is to define goals and land use policies for compliance with the California Coastal Act. It is intended to restore the overall quality of the Venice Coastal Zone environment and its natural and man-made resources and assures that public coastal access and public recreation areas are provided as required per the Coastal Act.

3.8.1.5 Land Use Entitlements for Project

The VAPP includes the construction of a new pumping plant with a two-story electrical building and control facility, three submersible pumps, and an associated valve and metering vault. It also includes the improvement of an adjacent vacant lot (128 Hurricane Street) that will contain eight parking spaces, open space, and the potential for public art (see Figure 2-2 in Chapter 2, Project Description, of this EIR). The design of the building and accessory uses include encroachment of a structure over six feet into the rear yard and eight parking spaces. This project is considered a Public Facilities use, which is not allowed by right in a RW2-1 zone or in a Medium Residential land use designation. The VAPP will need several land use entitlement approvals in order to be constructed. The City is evaluating various options: (1) Venice Specific Plan Project Compliance; (2) Public Benefits Project Compliance with Alternative Compliance; (3) RW2-1 Adjustment for Open Space; (4) and a Conditional Use for Parking. A local Coastal Development Permit and a state Coastal Development Permit are also required.

Venice Specific Plan Project Permit

The Venice Specific Plan Project Permit Compliance Review determination is issued for projects within the a Venice Coastal Zone. Venice Specific Plan projects are those projects located within the Venice Coastal Zone. The Director of Planning is the Approval Authority for a Venice Specific Plan Project Permit Compliance Review and must make findings of consistency with the Venice Specific Plan Findings. The Venice Specific Plan Project Permit Compliance Review is processed in compliance with Section 11.5.7 of the LAMC.

Public Benefits Project Permit Compliance

The Proposed Project has the option to pursue a Public Benefits Project Permit. The Proposed Project has uses that are applicable and can be permitted via a Section 14.6 Public Facility Public Benefits Project permit, with Alternative Compliance. Proposed uses, such as the Proposed Project, are permitted in any R zone (residential), provided these uses meet the performance standards or alternative compliance measures approved for the uses. Section 14.6 Public Facility Public Benefits Project indicates the following:

> Public utilities and public services uses and structures in the R zone include Performance Standards that provide for height, yards, setbacks, scale, landscaping, and open space, especially with the main buildings similar to other properties in the neighborhood. Signage, noise levels adjacent to residential uses should not be used at times or in a manner that would be disturbing to neighbors. Public telephones should not be located to encourage unwanted loitering. Sufficient off-street parking should be provided. The proposed use should be designed to minimize loitering on or near the site. The project should provide safe vehicular ingress and egress with no increase in traffic level of service to accommodate expected usage by the public and/or occupants of the facility, especially police and fire safety. Lighting should not reflect into nearby residential areas. Walls, fences, or other visible security devices should be similar to what is in the surrounding neighborhood. Graffiti should be monitored and removed immediately from site.

Adjustment for Yards

Section 12.28 of the LAMC authorizes a Zoning Administrator to grant adjustments to yard requirements. Although the Proposed Project has the option to pursue a Public Benefits Project Permit, it will be required to comply with the LAMC Section 12.09.5 RW2-1 Residential Waterways Zone yard requirements. Since the Proposed Project has an encroachment of over six feet within the rear yard, a YardAdjustment can remedy this issue, thereby bringing the Proposed Project into compliance with this requirement. A Yard Adjustment is appealable to the Area Planning Commission.

Conditional Use Permit for Parking

Parking on the Project Site will be located on the vacant lot located at 128 Hurricane Street. Per the Venice Specific Plan, the Proposed Project will require at least five on-site project automobile parking spaces. Since the parking would be located on an adjacent lot within 750 feet of the VAPP Project Site, a Conditional Use Permit for Parking will be required. The total number of parking spaces that will be provided on the 128 Hurricane Street lot is eight.

The initial decision on a Conditional Use application requires City Planning Commission consideration and is appealable to the City Council and/or Mayor. The Planning Commission has a range of findings it can make, including approval in whole or in part with or without conditions, or denial of the application. In addition, a public hearing must be held and three Findings of Approval must be granted and include the following: (1) That the project will enhance the built environment in the surrounding neighborhood or will perform a function or provide a service that is essential or beneficial to the community, city, or region; (2) That the project's location, size, height, operations, and other significant features will be compatible with and will not adversely affect or further degrade adjacent properties, the surrounding neighborhood, or the public health, welfare, and safety; and (3) That the project substantially conforms with the purpose, intent, and provisions of the General Plan, the applicable community plan, and any applicable specific plan.

3.8.1.6 Proposed Project Coastal Development Permits

The Proposed Project must obtain a local Coastal Development Permit and a state Coastal Development Permit from the California Coastal Commission. Coastal Development Permits are regulatory permits that projects located in the California Coastal Zone utilize to ensure compliance with the California Coastal Act. Coastal Development Permit authority for the Proposed Project is delegated to the California Coastal Commission, since the Venice Coastal Zone does not have a California Coastal Commission certified Local Coastal Program. For public infrastructure projects and those projects constructed in the public right of way, the City Engineer at the Los Angeles Department of Public Works, Bureau of Engineering, makes findings of consistency with the policies of the Coastal Act at a local level and has the authority to issue local Coastal Development Permits. For private projects, to support the planning entitlements process, the Department of City Planning, through the Venice Specific Plan and the Venice Coastal Land Use Plan, also evaluate consistency with the Coastal Act and have the authority to issue local Coastal Development Permits. For the Proposed Project, the Departments of Public Works and City Planning will work together to ensure that the Proposed Project is consistent with the Coastal Act, Venice Specific Plan, and Venice Coastal Land Use Plan.

3.8.2 Environmental Setting

This section describes the environmental setting or conditions related general plan land use, zoning, and applicable plans. The information in this section is used in preparing the evaluation and conclusions of the impact analysis as well as determining the required mitigation measures.

As described in Chapter 2 (Project Description), the Project Site comprises three undeveloped vacant Residential lots, zoned RW2-1. All three lots are owned by the City of Los Angeles and located next to the existing Venice Pumping Plant (VPP). The site addresses are 3813 and 3817 South Esplanade and 128 Hurricane Street (Laydown Area 1). The three lots are not contiguous and are separated by Hurricane Street and Canal Court (see Chapter 2, Figure 2-2, Project Location Map, of this EIR).

There are three construction Laydown Areas that will be used for materials and equipment storage and for construction staging during the anticipated 2-year construction period. Laydown Area 1 is located at 128 Hurricane Street, which is already part of the Project Site. Laydown Area 2 is comprised of two lots that are located at 3819 and 3821 Via Dolce across the Venice Grand Canal, east of the Project Site and is accessed from Via Dolce. Laydown Area 3 is located at 9940 Jefferson Boulevard in Culver City, which is approximately 7 miles west of the Project Site. Laydown Area 3 is owned by the City of Los Angeles.

The Project Site is highly urbanized within the Ballona Lagoon West sub-area of Venice, north of Ironside Street. It contains a mix of residential, open space, and public facility land uses. The Proposed Project is considered infill development. North and west of 3813 and 3817 South Esplanade are single- and multi-family residential uses. To the east is the Venice Canal System, which is designated as open space. To the south is the VPP, which is a public facilities land use.

The 128 Hurricane Street lot is bounded by the Ballona Lagoon to the south, Hurricane Street to the north, multi-family residential to the west, and Canal Court and the VPP to the east.

Laydown Areas 1 and 2 are bounded by single- and multi-family residences to the north, south, and east and by multi-family residences and the Grand Canal to the west.

Laydown Area 3 in Culver City is located within a light industrial/commercial area and adjacent to educational uses (i.e., West Los Angeles College).

3.8.2.1 General Plan Zoning and Land Use Designations

Zoning

Los Angeles Municipal Code

The Project Site and Laydown Areas 1 and 2 are located in the RW2 Zone. This designation includes lots that front on navigable public canals or waterways that may have historical significance, unique present conditions, close proximity to recreational water areas, and are located in areas that enjoy optimum climatic conditions. The RW2 Zone has the following requirements:

- **Use** - Residential and Accessory Uses
- **Area** – No building or structure shall be erected or maintained nor shall any building or structure be enlarged unless the following yards and lot areas are provided and maintained in connection with such building, structure or enlargement:
- **Front Yard** – 15 feet
- **Side Yards** – not less than ten percent of the width of the lot, but in no event of less than three feet in width.
- **Rear Yard** – There shall be a rear yard of not less than 15 feet in depth. Notwithstanding any provisions of this article to the contrary, the rear lot line is that line opposite and most distant from the lot line separating the narrowest canal frontage of the lot from the navigable public canal or waterway.
- **Lot Area** – Every lot shall have a minimum width of 28 feet and a minimum area of 2,300 square feet. The minimum lot area per dwelling unit shall be 1,150 square feet.
- **Open Space** – Same as required in "RW1" Zone – Section 12.08.5 C.5.

Culver City Municipal Code

Laydown Area 3 in Culver City is zoned Industrial General (IG). Per the Culver City Municipal Code, this designation is applied to areas appropriate for a wider variety of industrial uses than the Light Industrial (IL) District, including outdoor activities, but no heavy industry. The IG Zoning District is consistent with the Industrial land use designation of the General Plan.

Land Use Designation

Venice Community Plan

The Land Use designation for the Project Site and Laydown Areas 1 and 2 is Multiple Family Residential. This is defined as all multiple-family residential development of five or more units.

Culver City General Plan

Laydown Area 3 in Culver City has a land use designation of Industrial. The General Plan indicates that this designation is intended to strengthen and protect successful existing uses, while encouraging desirable and creative new development, including manufacturing and industrial, but excluding heavy industrial.

Development Standards and/or Principles

The following identifies land use and development regulations applicable to the Project Site, based upon its current general plan land use designations and zoning within the applicable plans. This information is included here in order to determine later in the analysis if the Proposed Project would be consistent with these requirements and if not, what land use and zoning actions would be needed. It should be noted that the information below does not address development standards or principles associated with Laydown Areas 2 or 3 since these sites would only be used temporarily for construction activities and once the Proposed Project is constructed, returned to their original use and condition (currently vacant lots).

Los Angeles Green Building Code

The Los Angeles Green Building Code (LAGBC) applies to the non-residential construction of all new buildings, all building alterations with a building permit valuation of over $200,000, and all building additions. This includes construction, alteration, replacement, repair, use and occupancy, and demolition of all structures connected to applicable buildings. The Los Angeles Green Building Code requires mandatory design elements in Planning and Design, Energy Efficiency, Water Efficiency & Conservation, Material Conservation and Resource Efficiency, and Environmental Quality.

Venice Community Plan

The following design guidelines are identified for land use designations and zoning for Multiple Family Residential.

Site Planning - All multiple-family residential development of five or more units should be designed to the extent feasible around a landscaped focal point or courtyard.

Design - The design of all buildings shall be of a quality and character that improves community appearances by avoiding excessive variety or monotonous repetition. This can be accomplished through:

- Requiring the use of articulations, recesses, surface perforations, and/or porticoes to break up long, flat building facades.
- Utilizing complementary building materials on building facades.
- Incorporating varying design to provide definition for each floor.
- Integrating building fixtures, awnings, or security gates, into the design of building(s).
- Screening of all roof top equipment and building appurtenances from view.
- Requiring decorative, masonry walls to enclose trash.

Venice Coastal Zone Specific Plan

The Project Site is located in the Ballona Lagoon West Bank Sub-area of Venice north of Ironside Street, generally bounded by Driftwood Street on the north; Via Marina on the south; Ballona Lagoon on the east; and Strongs Drive, Canal Court, and Pacific Avenue on the west. The following are applicable Development Standards from the Venice Specific Plan.

Height - Within 60 feet of the mean high tide of the Ballona Lagoon or inland side of the Esplanade (City right-of-way), whichever is furthest from the water as determined by a licensed surveyor, Venice Coastal Development Projects shall not exceed a maximum height of 30 feet. Beyond 60 horizontal feet, one additional foot in height is permitted for each two additional horizontal feet to a maximum height of 38 feet. No portion of any structure (including Roof Access Structures, roof deck railings, and Architectural Features) shall exceed the 30 foot height limit within 60 horizontal feet of the mean high tide line of Ballona Lagoon or the inland side of the Esplanade, whichever is furthest from the water.

Lagoon Buffer/Setback/Yards - Lots located north of Ironsides Street:

1. All Venice Coastal Development Projects shall be set back an average of 15 feet but not less than ten feet from the lot line nearest to the water.
2. An open, permeable yard with an area of at least 15 times the lot width and a minimum of 450 square feet shall be maintained between the property line that faces the water and the front of any structure. No building extensions, including stairs and balconies, shall be allowed in the required permeable yard area, except for ground level permeable decks that do not exceed 18 inches in height.
3. The combined height of any decks, railings, garden walls, and fences situated within the required permeable yard shall not exceed six feet above the elevation of the adjacent public walkway.
4. The sideyard shall be consistent with LAMC requirements, but shall not be less than 3 1/2 feet.

Fill - No Fill shall be permitted in the lagoon and buffer area, except for the minimum amount necessary for habitat restoration and public access.

Drainage - Prior to issuance of a building permit for a new Venice Coastal Development Project or an expansion of the existing building footprint by more than ten percent, the applicant shall submit drainage plans to the Department of Building and Safety for its approval. All drainage for new construction shall be directed away from Ballona Lagoon. The applicant and all successors in interest shall maintain the approved Venice Coastal Development Project consistent with the drainage plans approved by the Department of Building and Safety.

Lot Consolidation - Ballona Lagoon West residentially-zoned lots are allowed a maximum of two residentially-zoned lots to be consolidated provided the Venice Coastal Development Project conforms with the following applicable development standards:

- Buildings shall be designed with visual breaks or Architectural Features, including balconies or terraces, with a change of material or a break in the plane for every 20 feet in horizontal length and every 15 vertical feet. Residential buildings shall provide habitable space on the Ground Floor, a ground level entrance, and landscaping and windows fronting the street.
- For residential Venice Coastal Development Projects, front porches, bays and balconies shall be provided to maximize architectural variety.

Venice Specific Plan Findings of Consistency

Venice Specific Plan Findings of Consistency are required to grant a Project Permit Compliance Review in the Venice Coastal Zone. The Approving Authority, the Director of Planning must make each of the Findings:

- That the Venice Coastal Development Project is compatible in scale and character with the existing neighborhood, and that the Venice Coastal Development Project would not be materially detrimental to adjoining lots or the immediate neighborhood;
- That the Venice Coastal Development Project is in conformity with the certified Venice Local Coastal Program;
- That the applicant has guaranteed to keep the rent levels of any Replacement Affordable Unit at an affordable level for the life of the proposed Venice Coastal Development Project and to register the Replacement Affordable Units with the Los Angeles Department of Housing;
- That the Venice Coastal Development Project is consistent with the special requirements for low- and moderate-income housing units in the Venice Coastal Zone as mandated by California Government Code Section 65590 (Mello Act).

Venice Local Coastal Program Land Use Plan

The Venice LCP-LUP notes the following for the Ballona Lagoon West Sub-area North of Ironside Street in which the Project Site is located:

Height - The maximum allowable building height for the Project Site is 30 feet within 60 horizontal feet of the mean high tide line of Ballona Lagoon, Grand Canal or the inland side of the Esplanade (City right-of-way), whichever is furthest from the water. Beyond 60 horizontal feet, one foot in additional height is permitted for each two additional horizontal feet to a maximum height of 38 feet. It also notes the following:

- All building heights shall be measured from the elevation of the fronting right-of-way, except on lagoon lots where all building heights shall be measured from the average existing natural grade.
- No portion of any structure (including roof access structures, roof deck railings and architectural features) shall exceed the 30-foot height limit within 60 horizontal feet of the mean high tide line of Ballona Lagoon, Grand Canal, or the inland side of the Esplanade (City right-of-way).
- Notwithstanding other policies of this LUP, chimneys, exhaust ducts, ventilation shafts, and other similar devices essential for building function may exceed the specified height limit in a residential zone by five feet.

Lot Consolidation - Concerning lot consolidation, the LCP notes that no more than two lots may be consolidated in the Ballona Lagoon West sub-area north of Ironsides Street in which the Project Site is located and provided that:

- No building or structure shall be constructed on what were more than two contiguous lots prior to lot consolidation with the exception of subterranean development that is entirely below street elevation.
- Building facades shall be varied and articulated to provide a pedestrian scale which results in consistency with neighboring structures on small lots. Such buildings shall provide habitable space on the ground floor, a ground level entrance and landscaping and windows fronting the street. No increase in the number of units shall result from the lot consolidation.
- Front porches, bays and balconies shall be provided to maximize architectural variety.

Use - Two units per lot including duplexes.

Density - One unit per 1,500 square feet of lot area.

Esplanade - The Esplanade (City right-of-way) shall be maintained and improved in order to provide for continuous public pedestrian access along Ballona Lagoon and the Grand Canal waterway.

Grand Canal and Lagoon Buffer/Setback - In order to provide a setback for public access, visual quality, and to protect the biological productivity of the canals, an average setback of 15 feet, but not less than 10 feet, shall be maintained in the front yard adjacent to the property line nearest the water.

Yards - Minimum side yard of 3 ½ feet. An open, permeable yard of at least 450 square feet for a 30-foot wide lot, and at least 600 square feet for a 40-foot wide lot, shall be maintained between the lagoon/canal property line and the front of any structure. A minimum 10-foot front yard setback, with a required 15-foot setback average, shall provide the required permeable front yard area. No building extensions, including stairs and balconies, shall be placed in or over the required permeable front yard area with the exception of permeable decks. The total combined height of any deck, deck railings, garden walls and/or fences situated within the required permeable front yard area shall not exceed 6 feet above the elevation of the adjacent public walkway.

3.8.2.2 Applicable Goals, Objectives, and Policies

Table 3.8-2 contains applicable project-related goals, objective, and policies associated with plans and programs governing the Project Site.

Table 3.8-2. Proposed Project Consistency with Applicable Plans and Goals, Objectives, and Policies

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Venice Local Coastal Program		
Policy I.A.1. Residential Development.	The maximum densities, building heights and bulks for residential development in the Venice Coastal Zone shall be defined by the Land Use Plan Maps and Height Exhibits (Exhibits 9 through 16), and the corresponding land use categories and the development standards as described in this LUP. Refer to Policies II.C.10 for development standards for walk streets and to Policies II.A.3 and 4 for parking requirements. b. Residential Lot Consolidations. In order to preserve the nature and character of existing residential neighborhoods, lot consolidations shall not be permitted in the Venice Canals and Silver Strand residential neighborhoods. No more than two lots may be consolidated in the Ballona Lagoon West, Ballona Lagoon (Venice Grand Canal) East, Southeast Venice, Milwood, North Venice and Oxford Triangle neighborhoods and on walk streets. Lot consolidations of not more than three lots shall be permitted in the Oakwood and Marina Peninsula residential neighborhoods. Lot consolidations may be permitted only subject to the following limitations: i. No building or structure shall be constructed on what were more than two contiguous lots prior to lot consolidation with the exception of subterranean development that is entirely below street elevation. ii. Building facades shall be varied and articulated to provide a pedestrian scale which results in consistency with neighboring structures on small lots. Such buildings shall provide habitable space on the ground floor, a ground level entrance and landscaping and windows fronting the street. No increase in the number of units shall result from the lot consolidation. iii. Front porches, bays and balconies shall be provided to maximize architectural variety.	No. The Proposed Project includes the consolidation of two lots, adjacent to the Venice Pumping Plant (VPP). The building's scale, massing, and design would complement the adjacent neighborhood's architecture and design. There would be no habitable space on the ground floor because the building would be used as an electrical and Control Room structure. A ground-level entrance and landscaping would be provided. Windows (including some faux windows) would be provided on both levels of the two-story building fronting the street and building's south side.
Policy I.A.5. Preserve and Protect Stable Multi-Family Neighborhoods	Preserve and protect stable multi-family residential neighborhoods and allow for growth in areas where there is sufficient public infrastructure and services and the residents' quality of life can be maintained and improved.	No. The Proposed Project would be designed in a manner that preserves and protects the multi-family residential neighborhood by following the Residential Citywide Design Guidelines and providing a high-quality building and landscaping design that complements the massing, scale, and architecture of the neighborhood. Although the building would function as an electrical and Control Room for the VPP and Venice Auxiliary Pumping Plant (VAPP), its appearance would be

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
		residential in nature. In addition, the provision of Open Space along the eastern portion of the VAPP and at 128 Hurricane Street, would introduce new green space within this area of the Venice community and would contribute to the resident's quality of life by providing passive recreation activities and unobstructed views of the Venice Grand Canal and Ballona Lagoon.
Policy I.A.7. Multi-Family Residential – Low Medium II Density	Accommodate the development of multi-family dwelling units in the areas designated as "Multiple Family Residential" and "Low Medium II Density" on the Venice Coastal Land Use Plan. The following is a summary of the Venice Specific Plan density and development standards for properties within the Ballona Lagoon West subarea North of Ironside Street: **Use:** Two units per lot including duplexes **Density:** One unit per 1,500 square feet of lot area **Esplanade:** the Esplanade (City right-of-way) shall be maintained and improved in order to provide for the continuous public pedestrian access along Ballona Lagoon and the Venice Grand Canal waterway. **Venice Grand Canal and Lagoon Buffer/Setback:** In order to provide a setback for public access, visual quality, and to protect the biological productivity of the canals, an average setback of 15 feet, but not less than 10 feet, shall be maintained in the front yard adjacent to the property line nearest the water. **Yards:** Minimum side yard of 3 ½ feet. An open, permeable yard of at least 450 square feet for a 30-foot wide lot, and at least 600 square feet for a 40-foot wide lot, shall be maintained between the lagoon/canal property line and the front of any structure. A minimum 10-foot front yard setback, with a required 15-foot setback average, shall provide the required permeable front yard area. No building extensions, including stairs and balconies, shall be placed in or over the required permeable front yard area with the exception of permeable decks. The total combined height of any deck, deck railings, garden walls and/or fences situated within the required permeable front yard area shall not exceed 6 feet above the elevation of the adjacent public walkway. **Height:** Not to exceed 30 feet within 60 horizontal feet of the mean high tide line of Ballona Lagoon, Venice Grand Canal or inland side of the Esplanade (City right-of-way), whichever is furthest from the water. Beyond 60 horizontal feet, one foot in additional height is permitted for each two additional horizontal feet to a maximum height of 38 feet. No portion of any structure (including roof access structures, roof deck	No. Although the Proposed Project is designated as RW2–1 (Residential Water Ways Zone) and the City of Los Angeles General Plan as Residential/Medium Residential, the proposed use (Public Facility) qualifies as a Public Benefits Project, per Article 4, Section 14.00 of the Los Angeles Municipal Code (LAMC). The LABOE will comply with the design criteria and development standards of Venice Specific Plan and the Residential Citywide Design Guidelines. The Open Space proposed along the east side of the VAPP would meet the front yard requirement along the Venice Grand Canal. The Proposed Project can meet the permeable Open Space requirement through a LAMC RW2-1 Zone Adjustment for Yards. This is needed to comply with rear yard setback requirements due to the facility's design which would include transformers that encroach into the rear yard more than the maximum 6 feet permitted. Similarly, there are Los Angeles Department of Water and Power (LADWP) facilities proposed to be located along Canal Court, which may not be able to meet local fencing requirements, due LADWP transformer design specifications. The building height (32 feet) would comply with building requirements. During construction of the Coastal Interceptor Sewer (CIS) diversion structure in the Venice Grand Canal, some fill derived from the canal would need to be stockpiled and then backfilled to cover the structure and to re-contour the western bank of the canal, which is proposed to be re-vegetated with native plants.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
	railings and architectural features) shall exceed the 30-foot height limit within 60 horizontal feet of the mean high tide line of Ballona Lagoon, Venice Grand Canal or inland side of the Esplanade (City right-of-way), whichever is furthest from the water. Notwithstanding other policies of this LUP, chimneys, exhaust ducts, ventilation shafts and other similar devices essential for building function may exceed the specified height limit in a residential zone by five feet. **Fill:** No fill shall be permitted in the lagoon. No fill may be placed in the lagoon buffer except for the minimum amount necessary for habitat restoration and public access.	
Policy I.D.1. Canals and Ballona Lagoon Waterways.	The Venice estuaries and wetlands including the Ballona Lagoon, Venice Canals, and Venice Grand Canal south of Washington Boulevard, are designated in the Land Use Plan as natural and coastal recreational resources, and are rezoned to the "Open Space" designation. Adjacent Use/Development: The only permitted development adjacent to the canals and lagoon shall be habitat restoration, single-family dwellings, public parks and walkways, subterranean or surface public parking lots, maintenance activities and emergency repairs. Surface public parking lots shall be permitted only where sufficient access and roadway capacity exists to accommodate such parking. New construction along the Canals, and Ballona Lagoon shall comply with standards for setbacks, noise barriers, landscape plan, pervious surfacing with drainage control measures to filter storm run-off and direct it away from environmentally sensitive habitat areas, buffer areas in permanent open space, land dedication for erosion control, and wetland restoration including off-site drainage improvements. For more details refer to the provisions contained in Policy Group I.A., Residential Land Use and Development Standards, and Policies IV.C.1 and IV.C.2, Stormwater Runoff and Circulation.	No. The Proposed Project entails development of a Public Facility on two lots designated in the General Plan as Medium Residential. As noted above, the Proposed Project qualifies as a Public Benefits Project, per the LAMC and therefore, would be considered a permitted use, if approved. The Proposed Project also includes restoration of a portion of the western bank of the Venice Grand Canal associated with installation of the CIS diversion structure. A Open Space along the eastern side of the Proposed Project adjacent to the Venice Grand Canal would provide both a buffer and serve as water quality treatment feature to capture and treat runoff from the site. As noted above, the site also includes drainage and water quality features designed to capture, contain, and treat stormwater runoff, consistent with applicable plans and policies.
Policy I.D.3. Views of Natural and Coastal Recreation Resources.	The scale of development shall comply with height limits, setbacks and standards for building massing specified in Policy Groups I.A and I.B, Residential and Commercial Land Use and Development Standards of this LUP, in order to protect public views of highly scenic coastal areas and vista points, including, but not limited to, the canals, lagoon, jetty, pier, Ocean Front Walk, walk streets and pedestrian oriented special communities.	No. As noted above, the Proposed Project qualifies as a Public Benefits Project and has been designed consistent with Venice the Residential Citywide Design Guidelines, and with design standards contained within the Venice Specific Plan. The building's massing, scale, design, and height would complement the adjacent residential neighborhood.
Policy V.A.1. General	Public services shall consider the competing needs of residents and visitors for use of roadways, existing parking, service systems, domestic water, public restrooms, etc., and shall allocate resources to expand the	No. The Proposed Project entails the construction of a critical facility necessary for the safe operation of the CIS and VPP and in order to reduce the potential for a catastrophic sewage spill into the Venice

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
	use of these existing facilities and create new facilities where necessary in a manner that they do not adversely affect residents. Public works projects shall be reviewed for consistency with the Coastal Act and the Venice Land Use Plan through the coastal development permit process as required by the Coastal Act.	Grand Canal, Ballona Lagoon, or adjacent street network. The Proposed Project would be constructed on three vacant lots owned by the City. Two of the lots would be consolidated and one is proposed for Open Space and parking for use by the adjacent residents. The analysis contained in the Draft Environmental Impact Report (EIR) determined that all impacts would be less than significant, except short-term noise and vibration and Greenhouse Gases. In addition, the Proposed Project would be required to obtain a Coastal Development Permit.
Policy V.A.3. Infrastructure	New sewer, storm drain, and water lines shall be installed using the least environmentally disturbing method feasible. The City of Los Angeles Department of Public Works shall develop a comprehensive citywide Storm Water Management Program, as discussed further in Implementation Strategy of Policy IV.C.1 of this LUP, to control stormwater run-off from new public and private developments and, where feasible, to remove pollutants from that run-off. Development of infrastructure shall precede or be constructed concurrently with the construction of developments or in lieu-fee should be paid.	No. The Proposed Project entails the construction of a critical facility necessary for the safe operation of the CIS and VPP and in order to reduce the potential for a catastrophic sewage spill into the Venice Grand Canal, Ballona Lagoon, or adjacent street network. The Proposed Project is part of a comprehensive Los Angeles Bureau of Sanitation (LABOS) and LABOE effort to upgrade and enhance critical sewage conveyance and pumping facilities throughout the city of Los Angeles in order to provide required redundancy and enhance safety.
Policy I.E.2. Scale.	New development within the Venice Coastal Zone shall respect the scale and character of community development. Buildings which are of a scale compatible with the community (with respect to bulk height, buffer and setback) shall be encouraged. All new development and renovations should respect the scale, massing, and landscape of existing residential neighborhoods. Lot consolidations shall be restricted to protect the scale of existing neighborhoods. Roof access structures shall be limited to the minimum size necessary to reduce visual impacts while providing access for fire safety. In visually sensitive areas, roof access structures shall be set back from public recreation areas, public walkways, and all water areas so that the roof access structure does not result in a visible increase in bulk or height of the roof line as seen from a public recreation area, public walkway, or water area. No roof access structure shall exceed the height limit by more than ten (10') feet. Roof deck enclosures (e.g. railings and parapet walls) shall not exceed the height limit by more than 42 inches and shall be constructed of railings or transparent materials. Notwithstanding other policies of this LUP, chimneys, exhaust ducts, ventilation shafts and other similar devices essential for building function may exceed the specified height limit in a residential zone by five feet.	No. As noted above, the Proposed Project qualifies as a Public Benefits Project, and has been designed consistent with the Residential Citywide Design Guidelines and the Venice Specific Plan. A high-quality design is proposed for the electrical building and would complement the scale, massing, design, and architecture of the adjacent residential neighborhood. A lot consolidation is proposed for the two contiguous lots adjacent to the existing VPP. The height of the electrical building would be 32 feet, which although above the 30-foot maximum includes roof access structures, etc. Exhaust ducts and other ancillary facilities associated with the building, except the heating and cooling mechanism (proposed to be constructed outside and at grade), would be contained within the building.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy I.E.3. Architecture	Varied styles of architecture are encouraged with building facades which incorporate varied planes and textures while maintaining the neighborhood scale and massing.	No. The proposed design of the electrical building would be developed to complement the scale, massing, design, and architecture of the adjacent residential neighborhood.
Policy I.F.3. Venice Canals	The historic integrity of the Venice Canals shall be preserved. The canals are deemed to be significant as an early example of community recreational planning in a coastal marshlands area. Included in the historic district are the six canals, their associated sidewalks and a number of pedestrian and vehicular bridges. The Venice Canals are listed on the National Register of Historic Places as an historic district (August 30, 1982). Additionally, the City of Los Angeles Cultural Heritage Commission declared the Venice Canal System a Los Angeles City Historic-Cultural Monument (HCM No. 270, August 2, 1983).	No. The Proposed Project would preserve the historical integrity of the Venice Canals, including the Venice Grand Canal and Ballona Lagoon. During project construction, temporary work within the Venice Grand Canal would be required to construct the CIS diversion structure. Subsequent to construction, this portion of the western bank of the canal would be restored with native plant communities. No impacts are anticipated to the Grand Canal or Ballona Lagoon. The Office of Historic Preservation would be consulted to ensure that the Proposed Project is compatible with the Venice Canals. Additionally, the Proposed Project would undergo design review by the City's Case Management Division and the Department of City Planning's Urban Design Studio in order to ensure that it is compatible with and does not adversely affect the Grand Canal and Ballona Lagoon.
Policy I.F.6. Archaeological Resources	Significant archaeological resources shall be protected from permanent loss. A preliminary cultural resources record search to determine the existence of significant archeological sites shall be required for developments which require more than minimal grading. Mitigation plans for the protection of such resources shall be required. If, during construction, any archaeological resources are discovered, work shall be stopped to prevent further disturbance of the resources, and the proper authorities shall be immediately notified.	No. The analysis contained in the Draft EIR indicates that impacts to Cultural Resources would be less than significant and no mitigation measures are required. Standard regulatory requirements would require the cessation of construction activities in the event Cultural Resources are discovered.
Policy II.A.3. Parking Requirements.	Public Utility Facility not having a Business Office on the premises: 2 spaces; plus 1 space for each 500 square feet of floor area. Parking shall be provided pursuant to a detailed parking study that demonstrates that the project will provide adequate parking to meet the needs of the development without causing negative impacts to coastal access or access to public recreational facilities.	No. The Proposed Project includes a total of eight parking spaces, five for on-site parking and three relocated off-site parking spaces. The Proposed Project requires a total of five on-site parking spaces. A total of four spaces are required to comply with the Venice Specific Plan and one parking space is required to comply with Beach Impact Zone Parking requirements. These spaces are allowed off-site, located within 750 feet of the property per LAMC 12.21 A.4 (g) and would be located on 128 Hurricane Street with a recorded covenant. Since the proposed parking area is R-zoned, a Conditional Use for Parking (LAMC 12.24) would be required to allow a parking lot on the R-zoned lot. Also since the parking would be removed and replaced with a red curb and/or a driveway along the southerly boundary of the Proposed Project along Hurricane Street, three spaces would be relocated on the 128 Hurricane Street lot. It should be noted that the Draft EIR

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
		determined that impacts associated with parking during operation of the Proposed Project would be less than significant and therefore, no mitigation measures are required.
Policy II.A.4. Parking Requirements in the Beach Impact Zone	Any new and/or any addition to commercial, industrial, and multiple-family residential development projects within the Beach Impact Zone shall provide additional (in addition to parking required by Policy II.A.3) parking spaces for public use or pay in-lieu fees into the Venice Coastal Parking Impact Trust Fund. Beach Impact Zone (BIZ) Parking Impact Trust Fund criteria: a. Commercial and industrial projects in the BIZ shall provide one additional parking space for each 640 square feet of floor area of the ground floor. Up to 50% of the total number of these additional parking spaces required in this section may be paid for in lieu of providing the spaces. c. All in-lieu fees shall be paid into the Venice Coastal Parking Impact Trust Fund to be administered by the City of Los Angeles Department of Transportation for improvement and development of public parking facilities that support public access to the Venice Coastal Zone. d. In no event shall the number of BIZ parking spaces (over and above those spaces required by the parking requirements set forth in Policy II.A.3) required for projects of three or more dwelling units, or commercial or industrial projects, be less than one (1) parking space for residential projects and two (2) parking spaces for commercial and industrial projects.	No. See response immediately above.
Policy II.A.9. Protection of Public Parking	The following policies shall be implemented and enforced in order to protect and enhance public parking opportunities provided on public rights-of-way and in off-street parking areas. b. Street Ends. It is the policy of the City to not permit privatization of street ends. Public parking opportunities shall be protected and encouraged at improved and unimproved street-ends that abut Ocean Front Walk and/or the beach. c. Rights-of-Way. In order to maintain and increase the public parking supply, the City shall maximize and protect the availability of public parking opportunities on city streets that currently accommodate vehicular traffic.	No. See response immediately above.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy II.C.1. General Non-Vehicular Coastal Access Policy	Pedestrian and bicycle access ways are identified on Exhibit 19. Pedestrian Access and Bicycle Trails shall be developed, protected and maintained, and new development adjacent to the coast and coastal waterways shall be required to provide public access in a manner that is consistent with the policies of the Coastal Act.	No. The Proposed Project would introduce a new public Coastal Access point at 128 Hurricane Street that includes walking trails that lead to the coastal waterway. Public access to the coast and coastal waterways would not be removed as a result of the Proposed Project. The Esplanade walking trail adjacent to the Project Site would be maintained and protected consistent with the CA Coastal Act.
Policy II.C.2. Venice Grand Canal Pedestrian Access.	The three existing public rights-of-way from the Venice Grand Canal to Strongs Drive and Pacific Avenue shall be improved and appropriately signed. South of Washington Boulevard, the public walkways that provide public pedestrian access along both sides of Venice Grand Canal shall be improved and appropriately signed.	No. With the exception of temporary closure of the Esplanade between the northern project boundary and eastern terminus of Hurricane Street during construction of the CIS diversion structure within the Grand Canal, access to this portion of the canal would not be inhibited. It should be noted that Open Space located along the eastern portion of the VAPP site is proposed and would provide pedestrians with additional access and viewing point of the Venice Grand Canal. Signage indicating the Open Space is accessible to the public would be included.
Policy II.C.3. Ballona Lagoon Enhancement Plan (Pedestrian Access).	Pedestrian access and interpretative overlooks to the Ballona Lagoon shall be enhanced without invading the privacy of adjoining residents. The existing public walkway on the east bank of Ballona Lagoon, and the overlook on the southern end of the lagoon near Via Marina, shall be maintained and protected for public access. (Refer also to Policy IV.B.1).	No. Both of the Open Space proposed along the eastern boundary of the VAPP, fronting the Grand Canal and the vacant lot located at 128 Hurricane Street, which faces the Ballona Lagoon, would be accessible to the public.
Policy II.C.11. Encroachment into Walk Street Right-of-Way	Encroachments into City right-of-way shall be limited to grade level uses including gardens, patios, landscaping, ground level decks and fences. The gardens/patios in the right-of-way, between the fences and the buildings, shall be permitted to provide a transitional zone between the public path ways and private dwellings. To create a defensible space, the planting along the walk streets shall not impede the view of walkways by the residents and the view of the gardens by the pedestrian. Creative use and arrangement of permeable paving materials shall be encouraged. Any fence, wall or hedge erected in the public right-of-way shall not exceed 42 inches in height as measured from the existing grade of the public right-of-way. The use of decorative fence patterns such as split rail, picket and rustic is encouraged. New fences shall be located in line with existing fences on the same side of the street.	No. The Proposed Project does not include encroachment into the City right-of-way. The Open Space provided along the eastern boundary of the VAPP would serve as a buffer between the facility and the Grand Canal. Landscaping within this area would be limited to native species, turf or other permitted groundcovers or landscaping materials. The provision of this space would also be consistent with the hydrology and water quality design intended to capture, retain, and treat stormwater runoff originating from the Project Site. Portions of the surface areas of the VAPP would utilize decomposed granite, which would serve as a permeable paving material. Fencing materials used would follow City requirements, except the location in which LADWP facilities are proposed (along Canal Court) since these require certain design standards intended to protect the public and these facilities from vehicle damage.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy III.A.1. General	New recreational opportunities should be provided, and existing recreational areas, shown on Exhibits 19a through 21b, shall be protected, maintained and enhanced for a variety of recreational opportunities for both residents and visitors, including passive recreational and educational activities, as well as active recreational uses. a. Recreation and visitor-serving facilities shall be encouraged, provided they retain the existing character and housing opportunities of the area, and provided there is sufficient infrastructure capacity to service such facilities. b. Acquisition, expansion and improvement of parks and facilities throughout the Venice Coastal Zone shall be encouraged and accelerated, subject to the availability of funds. c. Where feasible and compatible with the surrounding neighborhood, recreational uses shall be located in conjunction with other new public facilities, such as public parking lots.	No. As noted above, Open Space is proposed and would include the eastern boundary of the VAPP adjacent to the Grand Canal and a vacant lot located at 128 Hurricane Street and fronting Ballona Lagoon. These two areas would provide passive recreation opportunities for area residents and visitors. The facilities would be maintained by the LABOS. Limited parking for non-motorized vehicles (e.g., bicycles) is proposed for 128 Hurricane Street, although the exact number of spaces has not been determined.
Policy III.D.1. General	Existing bodies of water, including the Venice Canals, Venice Grand Canal south of Washington Boulevard, Ballona Lagoon, and the Pacific Ocean and beaches, shall remain open to the public for recreational uses, as specified in this LUP.	No. The Proposed Project would not inhibit public use of the Grand Canal, the Ballona Lagoon, or the Pacific Ocean.
Policy III.D.5. Educational and Passive Recreational Use of Waterways	Educational use of coastal waterways by schools and other groups shall be encouraged. Passive educational and recreational opportunities shall be maintained and enhanced via a public walkway along the Venice Grand Canal and lagoon wetlands. The City shall establish observation areas with seating and shade, subject to the availability of sufficient space and funding, to provide opportunities for passive recreation in the lagoon and canals in such a manner as to provide public access, consider the privacy of adjacent residences, and to protect public views.	No. As noted above the two Open Space areas located along the eastern boundary of the VAPP and on the vacant lot located at 128 Hurricane Street would provide passive recreation and viewing areas of the Grand Canal and the Ballona Lagoon. The design of these spaces would also consider the privacy of adjacent residences and would provide expansive public views of the scenic resources.
Policy III.D.6. Venice Canals Parks	New parks, with parking to the rear, shall be considered on some of the City-owned lots on the canals, provided that such facilities are compatible with the existing residential use of the area.	No. See response immediately above. It should be noted that the Open Space proposed along the eastern boundary of the VAPP does not include sufficient space for parking. The vacant lot located at 128 Hurricane Street would provide an alternative location for parking spaces that would be removed along Hurricane Street.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy IV.A.2. Permitted Uses	Uses permitted in or adjacent to the canals shall be implemented in a manner to protect the biological productivity of marine resources and maintain healthy populations of marine organisms. Such uses as open space, habitat management, controlled nature study and interpretation, and passive public recreation use of walkways for birdwatching, photography, and strolling shall be encouraged and promoted.	No. The analysis contained in the Draft EIR determined that both construction and operational-related impacts to biological resources, with the incorporation of mitigation, would be less than significant. Pending construction of the CIS diversion structure, a portion of the western bank of the Grand Canal would be restored with native plant communities, which would result in direct benefits to local wildlife. The provision of two Open Space areas located along the eastern boundary of the VAPP, fronting the Grand Canal, and the vacant lot located at 128 Hurricane Street, fronting Ballona Lagoon, would provide passive recreation, birdwatching, photography, and strolling opportunities.
Policy IV.A.3. Venice Canals Landscape Buffer.	To protect the marine habitat, a one and one-half to two-foot-wide safety landscape buffer strip shall continue to be provided and maintained between the canal banks and sidewalks. Landscaping in the buffer strip shall consist of native coastal strand marshland or wetland vegetation as specified in the Venice Canals Rehabilitation Plan approved by Coastal Commission Coastal Development Permit 5-91-584.	No. Pending construction of the CIS diversion structure, a portion of the western bank of the Venice Grand Canal would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584. The restored area would extend from the northern boundary of the VAPP to the eastern terminus of Hurricane Street.
Policy IV.A.4. Venice Canals Setback and Yard Area	In order to provide a setback for access, to protect visual quality and the biological productivity of the canals, and to limit water runoff, a setback with an average depth of 15 feet (and a minimum depth at any point of 10 feet) shall be provided and maintained in the front yard areas of private residences (adjacent to the canal property line). This setback shall provide a permeable yard with an area at least 15 feet times the width of the lot line at the canal side. (See also Policy I.A.4a for details).	No. The Proposed Project must comply with the Venice Specific Plan Setbacks and Yard requirements. The Proposed Project can meet the permeable Open Space requirement but would need a RW2-1 zone Adjustment for Yards to comply with rear yard setback requirements due to the facility's design, which would include transformers taller than the maximum 6 feet that encroach into the rear yard. The LABOE however, proposes to provide an Open Space buffer approximately 15 feet in width between the Esplanade and VPP. This area would be serve a dual use purpose including Open Space for passive recreation and viewing of the Grand Canal and to capture, retain, and treat stormwater runoff originating from the VAPP. As noted above, pending construction of the CIS diversion structure, a portion of the western bank of the Venice Grand Canal would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584. The restored area would extend from the northern boundary of the VAPP to the eastern terminus of Hurricane Street.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy IV.B.1. Ballona Lagoon	b. Permitted Uses. Only uses compatible with preservation of this habitat shall be permitted in and adjacent to the lagoon. Uses permitted in or adjacent to the lagoon shall be carried out in a manner to protect the biological productivity of marine resources and maintain healthy populations of marine organisms. Such uses as open space, habitat management, controlled nature study and interpretation, and passive public recreation such as birdwatching, photography, and strolling shall be encouraged and promoted. No fill shall occur in Ballona Lagoon unless it is consistent with Coastal Act Section 30233 and is the least environmentally damaging alternative. No untreated runoff shall be directed into the lagoon.	No. The Open Space proposed at the vacant lot at 128 Hurricane Street would be used for passive recreation uses. It would also provide opportunities for birdwatching, photography, and strolling along the Esplanade. As noted in the analysis contained in the Draft EIR, implementation of the Proposed Project would result in less-than-significant impacts to biological resources during construction and operation, with the inclusion of mitigation measures. In addition, all runoff would be captured, retained, and treated on-site and would not be allowed to enter the Ballona Lagoon. Similarly, no fill is proposed within the lagoon.
Policy IV.B.3. Ballona Lagoon Development Standards.	The setbacks and height of buildings adjacent to the lagoon shall continue to be limited as provided in Policies I.A.4b, c, and d so that development is compatible with the continuance of the environmentally sensitive habitat.	No. The Proposed Project does not include the development of buildings adjacent to the Ballona Lagoon, only passive Open Space uses, which are compatible with the Environmentally Sensitive Habitat. Moreover as noted in the analysis contained in the Draft EIR, implementation of the Proposed Project would result in less-than-significant impacts to biological resources during construction and operation, with the inclusion of mitigation measures.
Policy IV.B.4. Lagoon and Venice Grand Canal Zoning.	The lots beneath the waterways of the Ballona Lagoon and Venice Grand Canal south of Washington Boulevard shall be rezoned as Open Space (OS). This zone protects recreational and scenic uses of the coastal area while providing for other uses which would benefit the public without significant impairment of the recreational and residential uses.	No. The Proposed Project does not propose any changes to the OS zone of the Grand Canal and therefore would not be incompatible with it, as indicated in the analysis contained in the Draft EIR. Moreover, the construction of the CIS diversion structure within the Grand Canal would be temporary and would not protrude above the bottom of the canal and into the water column and would not be visible to area residents or visitors, thereby protecting scenic views.
Policy IV.B.7. Venice Grand Canal Rehabilitation.	The Venice Grand Canal between Hurricane Street and Washington Boulevard shall be restored and maintained in order to improve water quality, aquatic habitat, and public pedestrian access along the waterway in a manner that is sensitive to the privacy of adjoining residents.	No. As noted above, pending construction of the CIS diversion structure, a portion of the western bank of the Venice Grand Canal, between the northern property boundary of the VAPP north to Washington Blvd., would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584.
Policy IV.C.1. Stormwater Runoff	All new public and private development, substantial rehabilitation, redevelopment or related activity, which discharges stormwater runoff into the Ocean, Ballona Lagoon, Venice Grand Canal south of Washington Boulevard or the Venice Canals shall be designed and conducted in compliance with the County-wide Municipal National Pollution Discharge Elimination System (NPDES) Stormwater Permit, issued by the California Regional Water Quality Control Board (RWQCB), the RWQCB approved Standard Urban Stormwater Mitigation Plan, and the NPDES General	No. The Proposed Project includes the provision of required Best Management Practices (BMPs) and low impact development (LID) features to address on-site hydrology and water quality conditions and potential impacts. The Project Site (including Open Space areas) would be designed to convey, capture, and treat stormwater runoff originating from these sites and to ensure that it does not enter off-site areas, including the Grand Canal or Ballona Lagoon. Stormwater would not drain into any adjacent waterways, it would be self-contained on

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
	Permit for Stormwater Discharges Associated with Construction Activity, issued by the State Water Resources Control Board (SWRCB), where applicable. Methods to improve water quality, such as the mitigation of the first-flush stormwater runoff entering coastal waterways, shall be imposed as conditions of development by the City of Los Angeles in accordance with SWRCB and RWQCB recommendations and regulations, and the Santa Monica Bay Restoration Project Action Plan in order to protect, restore, and where feasible, enhance the water quality and habitat of these waterways.	the Project Site. It should also be noted that the analysis contained in the Draft EIR determined that impacts related to hydrology and water quality would be less than significant with the implementation of mitigation measures.
Policy IV.C.2. Water Quality	Prior to issuance of building permits for all developments adjacent to the canals area, Venice Grand Canal and Ballona Lagoon, a grading and drainage plan indicating that low flow surface runoff is prevented from traveling directly from the lot into the coastal waterways by one or more of the following methods are recommended: Installation of green strip filters or equivalent pollution-reducing devices in all new private and public parking areas adjacent to the canals and lagoon; upgrading of existing illicit storm drain connections with French drains; surface runoff directed to an existing storm drain; lot sloped to drain toward the alley; and, front yards adjacent to the canals and lagoon shall be required to have a permeable surface, or where the surface is not permeable, provide a drainage system to prevent runoff directly into the lagoon or canals. An engineering and soils report to determine suitability of soils for french drains may be required.	No. See response directly above. In addition, runoff capture features are proposed on-site and a bioswale (Open Space area) is proposed along the eastern boundary of the VAPP adjacent to the Venice Grand Canal, which would prevent runoff from entering this waterbody. In addition, the green space proposed at 128 Hurricane Street would be developed to include similar stormwater runoff capture and treatment features to ensure that these flows do not enter Ballona Lagoon.
Policy IV.D.1. Venice Canals Habitat	The Venice Canals have been identified by the Least Tern Recovery Team as a foraging habitat for the Least Tern. Development within or adjacent to the canals that might affect this foraging habitat shall not be permitted.	No. As noted in the analysis contained in the Draft EIR, implementation of the Proposed Project would result in less-than-significant impacts to biological resources (including Least Tern) during construction and operation, with the inclusion of mitigation measures.
Policy IV.D.2. Ballona Lagoon Habitat	The Ballona Lagoon has been identified by the Least Tern Recovery Team as a critical habitat for the Least Tern for feeding. Development within or adjacent to the lagoon that might adversely impact the quality of this foraging habitat shall not be permitted.	No. See response directly above.
Policy IV.E.1. Maintenance	The banks, waterways and public walkways of the Venice Canals, Ballona Lagoon and Venice Grand Canal south of Washington Boulevard shall be periodically maintained by the City or other appropriate entity, to keep these areas free of accumulated trash and wastes, thereby maintaining the biological, water quality, recreational and aesthetic resources of these areas.	No. Both construction and operational-related waste would be disposed of properly within the VAPP. In addition, pending completion of the CIS diversion structure within the Venice Grand Canal, the western bank of the canal would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584. This is anticipated to have a beneficial impact on local wildlife by providing additional foraging habitat.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy IV.F.1	Diking, dredging and fill shall be permitted only in conjunction with an approved restoration plan and maintenance activity consistent with Coastal Act Section 30233. No construction shall be permitted on sandy beaches, except for construction in conjunction with approved recreational, ecological, and erosion control facilities. No fill shall be permitted in coastal waterways or below the seven foot contour for structures adjacent to the lagoon unless it is consistent with Coastal Act Section 30233 and is the least environmentally damaging alternative.	No. Construction of the CIS diversion structure would be required within the Grand Canal and would be accomplished via a temporary coffer dam. Once completed, the diversion structure would be located underground and beneath the canal and would not protrude into the water column. Dredged material would be collected and stored within one of the Laydown areas or at a landfill. A portion of the fill material would be returned to the site and used to cover the diversion structure located in the canal and to re-contour the western bank of the canal in the area used to access it, from the northern boundary of the VAPP to the eastern terminus of Hurricane Street. Once the diversion structure is completed, the western bank of the canal would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584.
Policy IV.G.1. Flood Setback	Potential flood hazard to residents along the west bank of the Ballona Lagoon and the east bank of the Venice Grand Canal shall be alleviated by increasing the development setback in the Silver Strand area and along the banks of the Venice Grand Canal and Ballona Lagoon (see Policies I.A.4 and 7), and by controlling erosion along the banks by the use of native flora.	No. As noted above, a portion of the western bank of the Venice Grand Canal would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584, which would assist in reducing erosion. In addition, the analysis contained in the Draft EIR determined that impacts associated with erosion would be less than significant with adherence to standard regulatory compliance measures and the implementation of mitigation measures.
Policy IV.G.2. Hazard Mitigation for New Construction.	Special development standards shall be developed for those areas within the Venice Coastal Zone which present potential flood and liquefaction hazards.	No. The analysis contained in the Draft EIR determined that no flooding would result during either construction or operation of the Proposed Project and that impacts associated with liquefaction hazards would be less than significant with the implementation of mitigation measures.
Policy V.A.4. Conservation Programs.	Conservation programs for public works services within the Venice coastal zone shall be encouraged and developed.	No. The restoration of a portion of the western bank of the Venice Grand Canal would assist the City in accomplishing this policy objective by replanting this area with native coastal plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584, which would assist in reducing erosion and enhancement of native habitat.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
General Plan Framework		
Infrastructure and Public Services – Wastewater Collection		
Goal 9A	Adequate wastewater collection and treatment capacity for the city and in basins tributary to City-owned wastewater treatment facilities.	No. The Proposed Project is intended to provide additional reliability and redundancy to the VPP. It would allow regular service and maintenance to occur without jeopardizing human and environmental health as a result of sewage spills from the VPP into the adjacent Grand Canal, Ballona Lagoon, or adjacent street network. The facility would also be planned and designed to consider future risks associated with global climate change, including sea-level rise, which could affect operation of the existing VPP.
Objective 9.2	Maintain the wastewater collection and treatment system, upgrade it to mitigate current deficiencies, and improve it to keep pace with growth as measured by the City's monitoring and forecasting efforts.	No. See response immediately above. It should be noted that the analysis contained in the Draft EIR determined that the Proposed Project would not induce growth and does not include land uses that are growth-inducing by nature, such as residential, commercial, and industrial.
Policy 9.2.4	Continue to implement programs to upgrade the wastewater collection system to mitigate existing deficiencies and accommodate the needs of growth and development.	No. See response immediately above.
Safety Element		
Goal 1	A city where potential injury, loss of life, property damage and disruption of the social and economic life of the city due to fire, water related hazard, seismic event, geologic conditions or release of hazardous materials disasters is minimized.	No. The Proposed Project is intended to provide additional reliability and redundancy to the VPP. It would allow regular service and maintenance to occur without jeopardizing human and environmental health as a result of sewage spills from the VPP into the adjacent Grand Canal, Ballona Lagoon, or adjacent street network. The facility would also be planned and designed to consider future risks associated with global climate change, including sea-level rise, which could affect operation of the existing VPP.
Policy 1.1.2	Disruption reduction. Reduce, to the greatest extent feasible and within the resources available, potential critical facility, governmental functions, infrastructure and information resource disruption due to natural disaster. [All EOO programs involving mitigation of disruption of essential infrastructure, services and governmental operations systems and prepare personnel for quickly reestablishing damaged systems implement this policy.]	No. As noted above, the VPP is a critical City facility and currently has no mechanism to by-pass sewage flows from the CIS and therefore, must remain operational continuously. In the event of a natural disaster, the provision of additional pumps and associated redundancy would likely allow the facility to operate, thereby reducing the potential for catastrophic system failure and emergency discharges of sewage to the Grand Canal, Ballona Lagoon, or adjacent street network.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy 1.1.3	Facility/systems maintenance. Provide redundancy (back-up) systems and strategies for continuation of adequate critical infrastructure systems and services so as to assure adequate circulation, communications, power, transportation, water and other services for emergency response in the event of disaster related systems disruptions. [All EOO programs that involve provision of back up systems and procedures for reestablishment of essential infrastructure, services and governmental operations which are disrupted implement this policy.]	No. The Proposed Project is intended to provide additional reliability and redundancy to the VPP. It would allow regular service and maintenance to occur without jeopardizing human and environmental health as a result of sewage spills from the VPP into the adjacent Grand Canal, Ballona Lagoon, or adjacent street network. The facility would also be planned and designed to consider future risks associated with global climate change, including sea-level rise, which could affect operation of the existing VPP.
Policy 1.1.4	Health/environmental protection. Protect the public and workers from the release of hazardous materials and protect city water supplies and resources from contamination resulting from accidental release or intrusion resulting from a disaster event, including protection of the environment and public from potential health and safety hazards associated with program implementation. [All EOO hazardous materials hazard and water pollution mitigation programs implement this policy.]	No. See response immediately above.
Conservation Element		
Objective:	Protect important cultural and historical sites and resources for historical, cultural, research, and community educational purposes.	No. The Venice Canal System is identified as City of Los Angeles Historic Cultural Monument No. 270 and is part of the Venice Historic Canal District (ZI–2370). The Grand Canal and Ballona Lagoon are located immediately adjacent to the Proposed Project. The analysis contained in the Draft EIR determined that no impacts to cultural resources, related to the Grand Canal or Ballona Lagoon would result with implementation of the Proposed Project. It should be noted however, that the City's Case Management Division and Urban Design Studio would assist with the design review of the Proposed Project. Additionally, the Office of Historic Preservation would be consulted to ensure that it is compatible with and does not adversely affect these Historic Resources.
Policy:	Continue to protect historic and cultural sites and/or resources potentially affected by proposed land development, demolition or property modification activities.	No. See response immediately above.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Open Space Element		
Goal:	To conserve unique natural features, scenic areas, cultural and appropriate historical monuments for the benefit and enjoyment of the public.	No. See response immediately above. As noted above, the Proposed Project would include the provision of two Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas are required by the Venice Specific Plan and would provide passive recreation areas to adjacent residents and visitors and would directly benefit the public.
	To conserve and/or preserve those open space areas containing the city's environmental resources, including air and water.	No. See response immediately above.
Objective:	To emphasize the importance of, and to preserve open space and natural features in private and public development.	No. See response immediately above.
Policies:	Ecologically important areas are generally considered open space and shall be so designated. The following shall apply: (a) to the extent feasible, ecologically important areas should be kept in a natural state; (b) in the event a project is proposed within an ecologically important area, an environmental impact report shall be prepared	No. The Proposed Project is not located within an Environmentally Sensitive Habitat Area, but is located immediately adjacent to one (i.e., Grand Canal and Ballona Lagoon). Per the requirements of the California Environmental Quality Act (CEQA), an EIR has been prepared for the Proposed Project. As noted above, the analysis contained in the Draft EIR determined that impacts to biological resources, including Environmentally Sensitive Habitat Areas, would be less than significant during both construction and operation, with the implementation of mitigation measures.
	Small parks, public and private, should be located throughout the city. Not only should recreation activities be provided, but an emphasis shall be placed on greenery and openness.	No. As noted above, the Proposed Project would include the provision of two green Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas are required by the Venice Specific Plan would provide passive recreation areas to adjacent residents and visitors and would directly benefit the public.
	Where development is allowed in ecologically important areas, the intensity of development should be kept at a minimum consistent with reasonable use of the land. All measures should be taken to protect these areas including buffering ecologically important areas from conflicting or detrimental uses.	No. The Proposed Project is not located within an Environmentally Sensitive Habitat Area but is located immediately adjacent to the Venice Grand Canal and Ballona Lagoon. As noted above, the analysis contained in the Draft EIR determined that impacts to biological resources, including Environmentally Sensitive Habitat Area, would be less than significant during both construction and operation, with the implementation of mitigation measures.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Mobility Element		
Objective:	Reduce the pollutant load of stormwater runoff to meet Total Maximum Daily Load standards.	No. The Proposed Project includes the provision of required BMPs and LID features to address on-site hydrology and water quality conditions and potential impacts. The Project Site (including Open Space areas) would be designed to convey, capture, and treat stormwater runoff originating from these sites and to ensure that it does not enter off-site areas, including the Grand Canal or Ballona Lagoon. It should also be noted that the analysis contained in the Draft EIR determined that impacts related to hydrology and water quality would be less than significant with the implementation of mitigation measures.
Policy 2.3 Pedestrian Infrastructure:	Recognize walking as a component of every trip, and ensure high-quality pedestrian access in all site planning and public right-of-way modifications to provide a safe and comfortable walking environment.	No. During construction of the CIS diversion structure within the Grand Canal, a portion of Esplanade, extending from the northern boundary of the VAPP to the eastern terminus of Hurricane Street, would be closed temporarily to the public, although adequate existing alternative access is available along Canal Court between Esplanade and Galleon Street.
Policy 5.5 Green Streets:	Maximize opportunities to capture and infiltrate stormwater within the City's public right-of-ways.	No. The Proposed Project includes the provision of required BMPs and LID features to address on-site hydrology and water quality conditions and potential impacts. The Project Site, especially the Open Space areas, would be designed to convey, capture, and treat stormwater runoff originating from these sites and to ensure that it does not enter off-site areas, including the Grand Canal or Ballona Lagoon. It should also be noted that the analysis contained in the Draft EIR determined that impacts related to hydrology and water quality would be less than significant with the implementation of mitigation measures.
Health Element		
Policy 2.2 Healthy Building Design and construction:	Promote a healthy built environment by encouraging the design and rehabilitation of buildings and sites for healthy living and working conditions, including promoting enhanced pedestrian-oriented circulation, lighting, attractive and open stairs, healthy building materials and universal accessibility using existing tools, practices, and programs.	No. The Proposed Project would include the construction of a high-quality building design that is attractive and complements the scale, massing, character, and architecture of the adjacent residential neighborhood. The building would be required to adhere with applicable building design standards, including the Venice Specific Plan and the Residential Citywide Design Guidelines, and LID design features would be also be required.
Policy 2.10 Social Connectedness:	Acknowledge the mental and physical health benefits of social connectedness by promoting and valuing public spaces, social interaction, relationship building, and resilience in community and urban design.	No. As noted above, the Proposed Project would include the provision of two Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas would provide passive recreation areas for adjacent residents and visitors and would encourage social interaction and connectedness by providing a communal gathering space.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Objective:	Increase the number of neighborhood and community parks so that every Community Plan Area strives for 3 acres of neighborhood and community park space per 1000 residents (excluding regional parks and open spaces)	No. The Proposed Project would add additional Open Space to the community. As noted above, the Proposed Project would include the provision of two Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas would provide passive recreation areas for adjacent residents and visitors. The provision of these spaces would assist the community in achieving its Community Plan Area goals.
Objective:	Increase access to parks so that 75% of all residents are within a ¼ mile walk of a park or open space facility	No. See response immediately above.
Venice Community Plan		
GOAL 1.	A SAFE, SECURE, AND HIGH QUALITY RESIDENTIAL ENVIRONMENT FOR ALL COMMUNITY RESIDENTS	No. The Proposed Project would include the construction of a high-quality building design and landscaping that are in keeping with the massing, scale, character, and architecture of the adjacent neighborhood. In addition, it would include the provision of safety features, including fencing, gated entry, security cameras, and nighttime lighting.
Objective 1-1	To provide for the preservation of the housing stock and its expansion to meet the diverse economic and physical needs of the existing residents and projected population of the Plan area to the year 2010.	No. The Project Site is currently vacant and does not include residential uses. Although its current General Plan Land Use designation permits the development of such uses, the construction of Public Benefits Project uses would not substantially affect the potential expansion of the housing stock within the community. Although the community is largely built out, there are additional parcels within the community that could be redeveloped with more intense residential development, provided that the applicable zoning permits these uses and intensities.
Policy 1-1.1:	Protect the quality of the residential environment and the appearance of communities with attention to site and building design.	No. The Proposed Project would include the construction of a high-quality building design and landscaping that complements the massing, scale, character, and architecture of the adjacent neighborhood. The Proposed Project would also be subject to design review by the City's Case Management Division and the Urban Design Studio. Additionally, the Office of Historic Preservation would be consulted to ensure that the proposed use is compatible with the Venice Canals, a City-designated historic resource.
Policy 1-1.3:	Protect existing single-family residential neighborhoods from new out-of-scale development and other incompatible uses.	No. See response immediately above.
Objective 1-3	To preserve and enhance the varied and distinct residential character and integrity of existing residential neighborhoods	No. See response immediately above.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Policy 1-3.1	Seek a higher degree of architectural compatibility and landscaping for new infill development to protect the character and scale of existing residential neighborhoods.	No. See response immediately above.
b	Sufficient land for a variety of industrial uses with maximum employment opportunities which are environmentally sensitive, safe for the work force and which have minimal adverse impact on adjacent uses.	No. The Proposed Project entails construction of a Public Facility and does not include Industrial uses. In addition, the current zoning and General Plan Land Use designations do not permit such uses to be constructed on-site. A total of two employees (per shift) would be employed on-site and would work three separate eight-hour shifts. As such, at any given time, these two employees would be on-site to operate and monitor the VAPP and VPP. As noted in the analysis contained in the Draft EIR, the Proposed Project would result in less-than-significant impacts during operation and only short-term impacts related to noise and vibration and greenhouse gases during construction, which is anticipated to last 18 months.
Objective 3-2:	To assure mitigation of potential negative impacts generated by industrial uses when they are located in proximity to residential neighborhoods and to improve the aesthetic quality of industrial uses.	No. See response immediately above. As noted above, the Proposed Project would include the construction of a high-quality building design and landscaping that complements the massing, scale, character, and architecture of the adjacent neighborhood. The Proposed Project would also be subject to design review by the City's Case Management Division and Urban Design Studio. Additionally, the Office of Historic Preservation would be consulted to ensure that the proposed use is compatible with the Venice Canals, a City-designated historic resource.
Policy 3-2.1:	Encourage new industrial uses adjacent to residential neighborhoods to mitigate their impact on the residential neighborhoods to the extent feasible.	No. See response immediately above.
Goal 4	Adequate recreation and park facilities which meet the needs of the residents in the plan area	No. The Proposed Project would add additional green space to the community. As noted above, the Proposed Project would include the provision of two Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas would provide passive recreation areas for adjacent residents and visitors. The provision of these spaces would assist the community in achieving its Community Plan Area goals.
Objective 4-2	To provide facilities for specialized recreational needs by utilizing existing public lands such as flood control channels, utility easements, or Department of Water and Power property.	No. See response immediately above.
Policy 4-2.1:	Flood control channels and other appropriate public lands should be considered for open space and recreational purposes.	No. See response immediately above.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Objective 4-3:	To ensure the accessibility, security and safety of parks by their users, particularly families with children and senior citizens.	No. As noted above, the Proposed Project would include the provision of two Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas would provide passive recreation areas for adjacent residents and visitors. The provision of these spaces would consider such issues as accessibility, security (including lighting), and safety of patrons, including families with children and senior citizens. The Open Space and any design elements would be subject to design review by the City's Case Management Division and the Urban Design Studio. Additionally, the Office of Historic Preservation would be consulted to ensure that the proposed use is compatible with the Venice Grand Canal and the Ballona Lagoon, a City-designated Historic Resource.
Policy 4-3.1:	Provide local residents and visitors alike adequate access to local recreational facilities.	No. See response immediately above.
Policy 4-3.2:	Ensure that parks are adequately illuminated for safe use at night.	No. See response immediately above.
Goal 5	A community with sufficient open space in balance with new development to serve the recreational, environmental, health and safety needs of the community and to protect environmental and aesthetic resources.	No. As noted above, the Proposed Project would include the provision of two Open Space areas, located along the eastern boundary of the VAPP and at a vacant lot at 128 Hurricane Street. These Open Space areas would provide passive recreation areas for adjacent residents and visitors. The provision of these spaces would assist the community in achieving its Community Plan Area goals. They would also allow unobstructed views of scenic resources, including the Grand Canal and Ballona Lagoon. In addition, the analysis contained in the Draft EIR determined that impacts to biological resources would be less than significant during both construction and operation, with the inclusion of mitigation measures.
Objective 5-1	To preserve existing open space resources and where possible develop new open space.	No. See response immediately above.
Policy 5-1.1	Encourage the retention of passive and visual open space which provides a balance to the urban development of the community.	No. See response immediately above.
Policy 5-1.2	The City should encourage continuous efforts by federal, state and county agencies to acquire vacant land for publicly-owned open space.	No. The Proposed Project would facilitate the acquisition of additional vacant land for publicly-owned Open Space at 128 Hurricane Street. This lot would be used for public parking and Open Space that would lead to the Esplanade Walking Trail.
Policy 5-1.3	Protect significant environmental resources from environmental hazards.	No. As noted above, the VPP is a critical City facility and currently has no mechanism to by-pass sewage flows from the CIS and therefore, must remain operational continuously. In the event of a natural disaster or unexpected emergency, the provision of additional pumps

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
		and associated redundancy would likely allow the facility to operate, thereby reducing the potential for catastrophic system failure and emergency discharges of sewage to the Grand Canal, Ballona Lagoon, or adjacent street network.
Policy 5-1.4	Protect and maintain unique open space areas, including the Venice Canals, Venice Grand Canal, Ballona Lagoon and beaches.	No. With the exception of temporary construction within the Grand Canal associated with the CIS diversion structure, the Grand Canal would not be permanently affected and would maintain its unique Open Space area. The proposed CIS diversion structure would be constructed underground beneath the Grand Canal and would not protrude into the water column, nor would it be visible from the water surface.
GOAL 12	A system of safe, efficient and attractive bicycle and pedestrian routes	No. The Proposed Project does include a bicycle or pedestrian route on 128 Hurricane that leads to the Ballona Lagoon Esplanade Trail. Also, the Proposed Project would include new Coastal Access and Open Space accessible to this new walkway. However, a portion of Esplanade from the northern boundary of the VAPP to the eastern terminus of Hurricane Street would be temporarily closed to the public during construction of the CIS diversion structure in the Venice Grand Canal. Alternate existing access would be available via Canal Court at Esplanade and Galleon Street.
Objective 12-1	To promote an adequate system of safe bikeways for commuter, school and recreational use.	No. See response immediately above.
Policy 12-1.2	Identify bicycle routes along major and secondary arterials in the community.	No. The Proposed Project does not include the provision of bicycle or pedestrian routes. However, it should be noted that the project would not preclude the development of designated bicycle routes along major and secondary arterials in the community.
Policy 12-1.3	Assure that local bicycle routes are linked with the routes of neighboring areas of the city.	No. See response immediately above.
Objective 12-2	To promote pedestrian-oriented access and routes that are safe, efficient and attractive for commuter, school and recreational use, and facilitate economic activity and access to transit facilities.	No. A portion of Esplanade from the northern boundary of the VAPP to the eastern terminus of Hurricane Street would be temporarily closed to the public during construction of the CIS diversion structure in the Venice Grand Canal. Alternate existing access would be available via Canal Court at Esplanade and Galleon Street.
Policy 12-2.1	Encourage the safe utilization of easements and/or rights-of-way along flood control channels, public utilities, railroad rights-of-way, and streets wherever feasible for the use of bicycles and/or pedestrians.	No. While construction of the Proposed Project will impact the use of the sidewalk along the Grand Canal by bicycles and pedestrians, an alternate route along Canal Court at Galleon Street will be provided during the construction phase. Pedestrian and bicycle access will be restored when construction is complete. Also, when the Proposed

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
		Project is complete, the development of the 128 Hurricane Street lot will provide additional new Open Space with pedestrian access adjacent to the Ballona Lagoon, leading to the Ballona Lagoon Esplanade Trail.
Policy 12-2.2	Require the installation of sidewalks in all new roadway construction and in significant reconstruction of existing roadways.	No. The Proposed Project does not include new roadway construction or significant reconstruction of existing roadways; however, the southerly boundary of the VAPP site would include improved sidewalks.
Objective 12-3	To protect, maintain and improve pedestrian access to coastal resources including the system of walk streets.	No. The Proposed Project includes improvement of Coastal Access at 128 Hurricane Street by introducing new Open Space with additional pedestrian access leading to the Ballona Lagoon Esplanade Trail. During construction, temporary closure of the Esplanade, from the northern boundary of the VAPP to the eastern terminus of Hurricane Street, would be required. However, existing alternate access along Canal Court at Esplanade and Galleon Street would be maintained, which would provide the public with adequate access options to the Grand Canal and Ballona Lagoon and associated Esplanade and interpretive trails.
Policy 12-3.1	Implement all the policies and programs pertaining to pedestrian access to coastal resources contained in the Venice Coastal Zone Land Use Plan.	No. See response immediately above. The Proposed Project would not hinder pedestrian access to Coastal Resources, as contained in the Venice Coastal Zone Land Use Plan.
Goal 13	A sufficient system of well designed and convenient onstreet parking and off-street parking facilities throughout the plan area	No. The Proposed Project will provide a total of eight parking spaces at the 128 Hurricane Street lot. A total of four parking spaces would be provided to serve employees, one space for the Beach Impact Zone parking requirement, and relocated parking spaces, which would be removed from the southerly boundary of the Proposed Project along Hurricane Street between Canal Court and Esplanade and relocated to 128 Hurricane Street. Two existing non-public off-street parking spaces at the VPP would be maintained inside the existing VPP. The analysis contained in the Draft EIR determined that impacts related to the relocation of existing public parking spaces at the eastern terminus of Hurricane Street would result in less-than-significant parking impacts and no mitigation measures would be necessary.
Objective 13-1	To provide an adequate supply of parking at appropriate locations in accordance with Citywide standards and community needs.	No. See response immediately above.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Goal 17	Preservation and restoration of cultural resources, neighborhoods and landmarks which have historical and/or cultural significance	No. The Proposed Project would include the construction of a high-quality building design and landscaping that would complement the massing, scale, character, and architecture of the adjacent neighborhood. The Proposed Project would also be subject to design review by the City's Case Management Division and the Urban Design Studio. Additionally, the Office of Historic Preservation would be consulted to ensure that the proposed use is compatible with the architectural styles of the Venice Canals, a City-designated historic resource.
Objective 17-1	To ensure that the Community's historically significant resources are protected, preserved and enhanced.	No. See response immediately above.
Goal 18	Preservation of the scenic and visual qualities of coastal areas.	No. See response immediately above. In addition, the Proposed Project would include the provision of two Open Space areas. One space would be located along the eastern boundary of the VAPP adjacent to the Venice Grand Canal. The other would be located at a vacant lot at 128 Hurricane Street, adjacent to the Ballona Lagoon. Both Open Space areas would help to preserve the scenic and visual qualities of coastal areas by providing expansive view opportunities of the Grand Canal and Ballona Lagoon. In addition, the analysis contained in the Draft EIR determined that visual impacts associated with the Proposed Project would be less than significant with the inclusion of mitigation measures.
Policy 18-1.1	The location and amount of new development should maintain and enhance public access to the coast.	No. The Proposed Project would require temporary closure of Esplanade, from the northern boundary of the VAPP to the eastern terminus of Hurricane Street during construction of the CIS diversion structure within the Grand Canal. During construction, existing alternate access along Canal Court at Esplanade and Galleon Street would be maintained to provide the public with adequate access options to the Grand Canal and Ballona Lagoon and associated Esplanade and interpretive trails.
Policy 18-1.2	The protection of estuaries and wetlands and the restoration and protection of the Venice Canals	No. As noted above, pending completion of the CIS diversion structure within the Venice Grand Canal, the western bank of the canal would be restored with native plant communities, consistent with Coastal Commission Coastal Development Permit 5-91-584. In addition, runoff originating from the Proposed Project would be captured on-site, retained, and treated and no flows would be allowed to enter either the Grand Canal or Ballona Lagoon.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
Design Principles for New Development	Any development occurring in the Venice Coastal zone is regulated by the Venice LUP and the Venice Coastal Zone Specific Plan. 1. Development will be guided by the following design principles: a. New development will be located in areas best served by existing road and utility systems. b. The design of new development will mitigate the impact of the new traffic generated on coastal recreation access roads. c. New development will be concentrated to preserve identified coastal resource values (i.e., wetlands, view corridors). e. Views of distinctive visual resources (e.g., bluffs, wetlands) will not be significantly disturbed. h. Open space buffer areas between new development, identified wetlands and support areas will be established.	No. As noted above, the Proposed Project qualifies as a Public Benefits Project and must comply with the Venice Specific Plan Development Standards, which include findings of consistency with the Venice Coastal Land Use Plan. The Proposed Project would consist of a high-quality design and landscaping that is consistent with the scale, massing, character, and architecture of the adjacent neighborhood. The Proposed Project also includes the provision of two Open Space areas. One would be located along the eastern boundary of the VAPP adjacent to the Grand Canal, while the other would be located at 128 Hurricane Street on a vacant lot. They would serve as buffer areas between the VAPP and these wetland resources and would provide expansive views of the Grand Canal and Ballona Lagoon. Moreover, the analysis contained in the Draft EIR determined that biological resources, traffic and transportation, and view-related impacts would be less than significant with the implementation of mitigation measures.
Coastal visual Resources	1. Protect existing views of the wetlands from the surrounding public streets and open space areas. 4. Landscaping and plant materials should be used to screen and soften visually obtrusive elements.	No. The analysis contained in the Draft EIR determined that Proposed Project impacts related to views would be less than significant with the implementation of mitigation measures. As noted above, the Proposed Project would include two Open Space areas that would provide expansive views of the Grand Canal and Ballona Lagoon, thereby protecting views of the wetlands. In addition, the building design and landscaping would be high-quality and would consider such elements as screening and softening visually obstructive elements.
Hazards Areas	3. Future development must be based on thorough site specific geologic and soils studies including specific geotechnical studies related to mitigation of liquefaction and lateral spreading. 4. All future development shall utilize earthquake-resistant construction and engineering practices particularly those intended for high density of human occupancy. Preliminary engineering mitigation and structural setbacks shall be designed for a bedrock acceleration of 0.5 g and high potential for liquefaction, unless a reliable geologic survey indicates otherwise. 5. Consider the effect of seismic sea waves in land use planning and development sitting.	No. The analysis contained in the Draft EIR determined that Proposed Project impacts related to geology and soils and hazards, including seismic sea waves and liquefaction, would be less than significant with the implementation of mitigation measures.
Public Works	1. Public works improvements in the study area shall be designed to protect sensitive habitat resources, accommodate new development permitted in the area and provide for future public access needs. 4. Installation of new sewer and water lines will be accomplished via the least environmentally disturbing method.	No. The analysis contained in the Draft EIR determined that Proposed Project impacts related to biological resources would be less than significant with the implementation of mitigation measures. As noted above, during construction of the CIS diversion structure within the Grand Canal, access along the Esplanade, between the northern

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
	5. Water conservation technology should be employed in the installation and operation of additional water service.	boundary of the VAPP and the eastern terminus of Hurricane Street, would not be available. During construction, there would be adequate existing access to both the Grand Canal and Ballona Lagoon along Canal Court at Esplanade and Galleon Street. Installation of new sewer and water lines would be made via adjacent connections and would be installed in a manner that would not be environmentally disturbing and would adhere to City requirements. The Proposed Project would include xeriscape landscaping and crushed granite or rock in outside surface areas, except for the two Open Space areas (described above). Water conservation measures required by the City would be implemented, as applicable.
Recreation and Park Facilities and Open Space	2. Ensure that parks, beaches and canals are adequately illuminated for safe use at night where appropriate. 4. Coordinate with the Department of Recreation and Parks and the Police Department to ensure adequate police patrons and the utilization of "defensible space" in the design of recreation and park facilities. 9. Target the provision of parks and recreation facilities in areas with the greatest deficiencies.	No. The two Open Space areas proposed along the eastern boundary of the VAPP and vacant lot at 128 Hurricane Street would be planned and designed in a manner that considers safety, including lighting. As noted above, the proposed Open Spaces would assist the Community Plan Area in achieving its Open Space and park acreage goals.
Community Design and Landscaping Guidelines		
Street Lighting	3. Any new street lighting or pedestrian lighting system built in the public right-or way must be designed to currently adopted City standards. Equipment must be tested and approved by the Bureau of Street Lighting. 4. New lighting systems will be designed to minimize glare and "light trespass".	No. As noted in the analysis contained in the Draft EIR, project impacts related to lighting (including glare) were determined to be less than significant with mitigation measures.
Venice Coastal Zone Specific Plan		
Section 10. A. Ballona Lagoon West Bank	1. Height. Within 60 feet of the mean high tide of the Ballona Lagoon or inland side of the Esplanade (City right-of-way), whichever is furthest from the water as determined by a licensed surveyor, Venice Coastal Development Projects shall not exceed a maximum height of 30 feet. Beyond 60 horizontal feet, one additional foot in height is permitted for each two additional horizontal feet to a maximum height of 38 feet. No portion of any structure (including Roof Access Structures, roof deck railings and Architectural Features) shall exceed the 30 foot height limit within 60 horizontal feet of the mean high tide line of Ballona Lagoon or the inland side of the Esplanade, whichever is furthest from the water.	No. See response above provided for Policy I.A.7. Multi-Family Residential – Low Medium II Density.

Plan Goal, Policy Or Objective Number	Applicable Goal, Policy, or Objective	Conflict with Applicable Plan, Policy, or Regulation?
	b. Lots located north of Ironsides Street: (1) All Venice Coastal Development Projects shall be set back an average of 15 feet but not less than ten feet from the lot line nearest to the water. (2) An open, Permeable yard with an area of at least 15 times the lot width and a minimum of 450 square feet shall be maintained between the property line that faces the water and the front of any structure. No building extensions, including stairs and balconies, shall be allowed in the required Permeable yard area, except for ground level Permeable decks that do not exceed 18 inches in height. (3) The combined height of any decks, railings, garden walls and fences situated within the required Permeable yard shall not exceed six feet above the elevation of the adjacent public walkway. (4) The sideyard shall be consistent with LAMC requirements, but shall not be less than 3 1/2 feet.	No. See response above provided for Policy I.A.7. Multi-Family Residential – Low Medium II Density. In addition, as noted above, the Proposed Project would include an Open Space area located along the eastern boundary of the VAPP adjacent to the Grand Canal and which would extend from the northern boundary to the eastern terminus of Hurricane Street. Moreover, electrical building would be constructed adjacent to Canal Court, approximately 50 feet west of Esplanade. The intervening areas would be comprised of hatches uses to access the submersible pumps and would include landscaping and permeable surfaces. The building design does not include any decks, railing, or garden walls. A RW2-1 Zone Yard Adjustment will be needed because the transformers in the rear yard encroach over 6 feet. Fencing would not exceed four feet above the elevation of the adjacent public walkway (Canal Court).
	3. Fill. No Fill shall be permitted in the lagoon and buffer area, except for the minimum amount necessary for habitat restoration and public access. 4. Drainage. Prior to issuance of a building permit for a new Venice Coastal Development Project or an expansion of the existing building footprint by more than ten percent, the applicant shall submit drainage plans to the Department of Building and Safety for its approval. All drainage for new construction shall be directed away from Ballona Lagoon. The applicant and all successors in interest shall maintain the approved Venice Coastal Development Project consistent with the drainage plans approved by the Department of Building and Safety.	No. See response above provided for Policy I.A.7. Multi-Family Residential – Low Medium II Density. In addition, per City requirements drainage plans would be submitted to the Department of Building and Safety. As noted above, the analysis contained in the Draft EIR determined that project impacts related to hydrology and water quality were less than significant with the mitigation measures.

3.8.3 Environmental Impact Analysis

3.8.3.1 Methodology

Potential significant impacts associated with the Proposed Project were based upon a review and assessment of applicable land use and zoning documents (see Table 2-1 [Chapter 2, Project Description]) of this EIR for a list of required permits), including the City of Los Angeles Municipal Code, the Venice Specific Plan, the City of Los Angeles General Plan Safety Element and Land Use Element (Venice Community Plan), and the Venice Local Coastal Program Land Use Plan. Permits and/or planning entitlements that may be pursued for this project include Public Benefits Project Permit review, Venice Specific Plan Project Permit Compliance review, Conditional Use for Parking, RW2-1 zone Adjustment for Yards, and California Coastal Commission Coastal Development Permit. City of Culver City requirements concerning the temporary use of Laydown Area 3 for soil stockpiling are also considered and evaluated.

Based upon these documents, an analysis was prepared to determine if the Proposed Project is consistent with the land use designations and zoning, as well as the applicable goals, objectives, and policies. Table 3.8-2 contains the results of the analysis and indicates if the Proposed Project would be "inconsistent." If an "inconsistent" determination is indicated, impacts related to land use and planning are not necessarily considered potentially significant since the overall context and intent must also be considered. Therefore, the discussion below identifies potential project-related impacts and the measures that would be required to mitigate these, if they are found to be potentially significant.

3.8.3.2 Screening Analysis

As noted in Section Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.8.3.3 Thresholds of Significance

According to Appendix G of the CEQA Guidelines, a project would normally have a significant impact on land use and planning if it would:

PLNG-1. Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?

According to the *L.A. CEQA Thresholds Guide*, a determination of significance shall be made on a case-by-case basis, considering the following factors:

PLNG-2. Whether the proposal is inconsistent with the adopted land use/density designation in the Community Plan, redevelopment plan, or specific plan for the site;

PLNG-3. Whether the proposal is inconsistent with the General Plan or adopted environmental goals or policies contained in other applicable plans;

PLNG-4. The extent of the area that would be impacted, the nature and degree of impacts, and the type of land uses within that area; and

PLNG-5. The number, degree, and type of secondary impacts to surrounding land uses that could result from implementation of the Proposed Project.

3.8.3.4 Construction Impacts

As noted in Table 2-1 (see Chapter 2, Project Description, of this EIR), there are land use entitlements and discretionary actions that would need to be obtained prior to the construction of the Proposed Project and therefore, it is assumed that these would be secured in advance of any construction activities. Similarly, as noted in Table 3.8-2, there are applicable goals, objectives, and policies that must be considered in approving the Proposed Project. These plans have been established in order to protect the environment and adjacent sensitive land uses and to ensure that the Proposed Project is consistent with the neighborhood's character and scale. As such, this section discusses the potential impacts that could occur during construction related to land use and zoning. As noted below, with compliance with applicable planning and zoning requirements, all impacts can be reduced to less than significant levels and no mitigation measures are required.

PLNG-1. Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.

As shown in Figures 3.1-3B (see Section 3.1, Aesthetics of this EIR) and described in Chapter 2 (Project Description), the Proposed Project would include a two-story electrical and control building, three submersible pumps, and an associated valve and metering vault. The building would be constructed along the westerly boundary of Project Site, would be approximately 32 feet in height, 50 feet in length, and 2,500 square feet (both levels combined) in area. The Project Site is zoned RW2-1 (Residential Waterways Zone), which allows for residential uses.

Laydown Area 2 is comprised of two lots, one located on private property and one owned by the County of Los Angeles. Laydown Area 1 is located on public land owned by the City of Los Angeles. Laydown Areas 1 and 2 are zoned RW2-1 (Residential Waterways Zone), which are intended for residential uses. Laydown Area 3 is located off-site in Culver City, seven miles east of the Project Site, and is intended for industrial uses.

Proposed building finishes include architectural stamped concrete, reveals, and impressions; metal awnings over each of the exterior doors and sustainable roofing (Sika Décor or similar); and painted surfaces with colors that blend in with the surrounding neighborhood. Windows would be located on the second level of the occupied space where employees work. It also includes the improvement of an adjacent lot that would contain a total of eight parking spaces, an option for public art, and open space. The design of the building and accessories include encroachment over six feet into the rear yard. The Proposed Project is considered a Public Facilities use, which is not allowed by right in a RW2-1 zone or in a Medium Residential land use designation.

The Proposed Project qualifies as a Public Benefits Project under the public utilities and public services use per LAMC Article 14, Section 14.00(b). Additional discretionary actions such as an Specific Plan Adjustment for Yards, Conditional Use for Parking would have to be processed with the Public Benefits Project Permit. Therefore, the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project and impacts are **less than significant**. No mitigation is required.

As noted previously, although the Venice LCP-LUP has been adopted by the City of Los Angeles, the Venice LCP-LUP has not been certified by the California Coastal Commission. Therefore, the VCP land use designation of Medium Residential and Open Space apply to the Project Site and Venice Grand Canal, respectively. Section 12.04.05.B.1(a) of the LAMC states that parks and recreation facilities, including bicycle trails, walking trails, nature trails used for park and recreation purposes; natural resource preserves including waterways; marine and ecological preserves, sanctuaries and habitat protection sites are all compatible with the Open Space land use designation.

The Open Space land use designation would not be affected since construction activities in the Venice Grand Canal associated with the diversion structure would be temporary, constructed below the canal, and would not protrude into the water column. Similarly, Laydown Areas 1 and 2 would only be used during construction of the Proposed Project and no permanent uses associated with the VAPP (excepting parking at Laydown Area 1) would be constructed on these parcels. As such, their current zoning of RW2 and General Plan land use designations of Medium Residential would not need to be changed. Therefore, neither construction of the diversion structure in the Venice Grand Canal nor use of Laydown Areas 1 and 2 would conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project and impacts would be less than significant. No mitigation is required.

Construction of the Proposed Project would require the use of machinery, materials, and personnel. These activities would require an area large enough to perform these operations safely and efficiently. As such, two temporary street closures would be required for the duration of the construction period; Hurricane Street between Canal Court and Esplanade; and Canal Court, extending from the VAPP's northern property boundary to Esplanade (see Figure 2-2, Project Location Map, in Chapter 2 of this EIR). The Proposed Project would be required to obtain a Temporary Street Closure permit from the Bureau of Street Services prior to construction to reduce impacts. This would ensure that the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project and therefore, impacts would be **less than significant** and no mitigation is required**.**

Construction activities within the Venice Grand Canal are under supervision of the U.S. Army Corps of Engineers and would be required to obtain applicable permits. Therefore, the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project. Impacts would be **less than significant** and no mitigation is required.

Construction of the diversion structure within the Venice Grand Canal would also require a number of preparation activities, including shoring, excavation, and construction of the temporary coffer dam. These activities would require work within the Venice Grand Canal and a portion of its western bank (see Figure 2-2, Project Location Map, in Chapter 2 of this EIR). Similarly, construction of the VAPP would entail the construction and installation of both above and belowground facilities, including the two-story electrical building and control facility and three submersible pumps and associated valve and metering vault. These activities within the Venice Grand Canal and Project Site

would be required to obtain necessary permits (see Table 2-1 in Chapter 2 of this EIR), including a Permit to Construct, prior to construction. Issuance of these permits would ensure that the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect. Therefore, impacts would be **less than significant** and no mitigation is required.

Stockpiling of soils and materials would be needed at all the Laydown Area sites during the construction period. Since three of these sites are owned by the City of Los Angeles, access for the other lot (owned by the County of Los Angeles) would need to be obtained from the property owners. For the privately owned parcel, a permission to enter (PTE) and encroachment permit would need to be obtained. The PTE and encroachment permit would need to be secured in advance of any construction permits. Similarly, a temporary use permit would be required from the City of Culver City to utilize Laydown Area 3. Issuance of these permits would ensure that the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect and therefore, impacts would be **less than significant** and no mitigation is required.

Minor grading may be required prior to excavation activities in order to prepare the Project Site for construction and the parking and open space area associated with the Laydown Areas. No grading is proposed for Laydown Areas 2 or 3. Once the Project Site is excavated and backfilled, additional minor grading may be required to construct the electrical building pad and to ensure proper drainage of the site. Grading activities would require a Permit to Construct, which would ensure that the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a General Plan, Specific Plan, Local Coastal Program, or Zoning Ordinance) adopted for the purpose of avoiding or mitigating an environmental effect and therefore, impacts would be **less than significant** and no mitigation is required.

The Venice Coastal Specific Plan establishes the amount of required parking for the Proposed Project and the California Coastal Act protects coastal street parking. Five parking spaces are required for the Proposed Project that would be located on the 128 Hurricane lot, within 750 feet of the Project Site. A Conditional Use Permit for Parking on this lot would be pursued in order for the parking requirements to be consistent with the Venice Specific Plan. On-street parking spaces located on Hurricane Street west of Canal Court are proposed to be relocated on the 128 Hurricane Street lot. Therefore, a total of eight parking spaces will be provided at the 128 Hurricane Street lot. Issuance of a Conditional Use Permit and a Coastal Development Permit would ensure that the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project, adopted for the purpose of avoiding or mitigating an environmental effect and therefore, impacts would be **less than significant** and no mitigation is required.

Because the Proposed Project would represent a new Public Facilities use within a Residential zone, it will need to be designed and constructed in a manner that is in keeping with the character of the existing residential neighborhood and as identified in the City's Municipal Code. The project would be required to adhere to goals, objectives, and policies related to siting and design, as contained in

the VCP and VSP. Although the exterior conceptual design has not been finalized, design features that are in keeping with the architecture, massing, and materials that are currently present on the adjacent residential structures will be provided.

The VLCPLUP and VSP have established urban development and design guidelines to ensure that development projects within the community are consistent with the character and scale of the neighborhoods in which they are proposed. Since the Land Implementation Plan of the Venice LCP has not been approved by the California Coastal Commission, the VSP is the controlling document for urban design and development standards for projects proposed within the Venice Coastal Zone. A review of the VSP indicates that there are no specific Design Guidelines for Public Facilities, such as the Proposed Project. In such incidents, and as noted in the VSP, the regulations of the Los Angeles Municipal Code apply. The Residential Citywide Design Guidelines are part of the City's General Plan Framework element and serve to implement the City's 10 Urban Design Principles.

The Proposed Project went through the Department of City Planning's Urban Design Studio and the Development Services Center required Design Review. They facilitated the application of design objectives and compliance with all planning requirements, including the VCP, VSP, and the VLCPLUP. These Design Guidelines do not supersede regulations in the municipal code.

In addition, due to its location adjacent to the Venice Grand Canal, a recognized historic resource (see Section 3.4, Cultural Resources of this EIR), it underwent design review by the City of Los Angeles Office of Historic Preservation to ensure its compatibility and consistency with this resource and the neighborhood in which it is proposed.

Through adherence to applicable plans and undergoing required design review, the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect and therefore, impacts would be **less than significant** and no mitigation is required.

The Residential Citywide Design Guidelines and Land Use and Development Regulations in the VSP would not apply to Laydown Areas 1 and 2, or to the diversion structure in the Venice Grand Canal, as these areas would not include permanent structures once construction of the Proposed Project is completed.

Therefore, the temporary use of all the Laydown Areas and construction of the diversion structure within the Venice Grand Canal would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project, impacts would **be less than significant.**

PLNG-2. Whether the proposal is inconsistent with the adopted land use/density designation in the Community Plan, redevelopment plan or specific plan for the site.

As noted above**,** impacts would be **less than significant** related to inconsistency with the adopted land use/density designation in the Community Plan, redevelopment plan, or specific plan for the site and no mitigation is required.

PLNG-3. Whether the proposal is inconsistent with the General Plan or adopted environmental goals or policies contained in other applicable plans.

Based upon the analysis above, impacts would be **less than significant** and no mitigation is required.

PLNG-4. The extent of the area that would be impacted, the nature and degree of impacts, and the type of land uses within that area.

The Venice Pumping Plant (VPP) was built in 1957 and the two vacant parcels proposed for the VAPP were obtained for future public facility uses. The residential land uses surrounding the Project Site were constructed subsequent to this time period beginning in the mid-1960s (see Section 3.4, Cultural Resources of this EIR) and continuing through the 2000s. The VPP is identified as the earliest building in the area. As noted above, the neighborhood is primarily comprised of residential uses, including single- and multi-family and is almost entirely built out. The construction of the VAPP represents a continuation of the Public Facilities use and which was present in the 1950s and was the first urban use in the neighborhood. As noted above, the Public Benefits Project section of the LAMC permits a Public Facility to be constructed in both the General Plan Land Use designation and LAMC zoning. In addition, the Proposed Project is required to obtain permits or entitlements in advance of construction activities. This would bring the Proposed Project into compliance with applicable plans and policies and ensure that a design review of proposed structures and materials by the Development Services Unit and Office of Historic Preservation are undertaken to consider its proximity to the Venice Grand Canal, a Historic Resource, and the neighborhood scale and character. As such, impacts related to the extent of the area that would be affected, the nature and degree of impacts, and the type of land uses within that area would be **less than significant** and no mitigation is required.

PLNG-5. The number, degree, and type of secondary impacts to surrounding land uses that could result from implementation of the Proposed Project.

The analysis contained in this EIR has determined that all impacts, with the exception of short-term construction-related noise and vibration impacts can be mitigated to less than significant levels with standard regulatory requirements or the implementation of mitigation measures (see Sections 3.1 through 3.11 of this EIR). In the case of construction-related noise and vibration impacts, these would be significant and unavoidable, even with mitigation incorporated, during the construction period, which is expected to last two years. Cumulative noise and vibration impacts during construction would also be significant and unavoidable. Therefore, the number, degree, and type of secondary impacts to surrounding land uses that could result from implementation of the Proposed Project during construction would be **significant and unavoidable**, even with the application of mitigation measures **MM NOI-1** and **MM NOI-2** identified in this EIR (see Section 3.9, Noise and Vibration).

3.8.3.5 Operational Impacts

This section discusses the potential impacts that could occur during operations related to land use and zoning and mitigation measures that may be required. As noted below, impacts are less than significant and no mitigation is required.

PLNG-1. Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.

Hurricane Street, between Canal Court and Esplanade currently separates the existing VPP from the proposed VAPP. Control of the two facilities would be administered via the control facility, housed in the two-story electrical building, once the construction of the VAPP is complete. Maintenance

activities, deliveries, and on-site operations would require employees and visitors to frequently enter and exit these two separate, but adjacent facilities. The curb along Hurricane Street, adjacent to the new VAPP site, would be changed to red and/or a driveway. The current on-street parking would be relocated to the 128 Hurricane Street lot. Because the VPP and VAPP are considered critical facilities, access would need to be controlled at all times. As discussed in Chapter 2 (Project Description), this would be achieved via security cameras, lighting, and perimeter fencing. Project parking for the VAPP would be located at the 128 Hurricane Street, just west of the existing VPP site. Therefore, the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect and therefore, impacts would be **less than significant**.

Impacts to land use and zoning were discussed previously and determined to be less than significant. Therefore, the Proposed Project would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to, a general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect and no mitigation measures are required.

PLNG-2. Whether the proposal is inconsistent with the adopted land use/density designation in the Community Plan, redevelopment plan or specific plan for the site.

Impacts related to consistency with an adopted land use plan were discussed previously and determined to be less than significant. Therefore, the Proposed Project would be consistent with the adopted land use/density designation in the Community Plan, redevelopment plan or specific plan for the site, and as such impacts would be **less than significant**, and no mitigation is required.

T-PLNG-3. Whether the proposal is inconsistent with the General Plan or adopted environmental goals or policies contained in other applicable plans.

Impacts related to consistency with an adopted land use plan, environmental goals or policies, or other applicable plans were discussed previously (see Table 3.8-2) and determined to be less than significant. Therefore, the Proposed Project would be consistent with the General Plan or adopted environmental goals or policies contained in other applicable plans, and as such impacts would be **less than significant**, and no mitigation is required.

T-PLNG-4. The extent of the area that would be impacted, the nature and degree of impacts, and the type of land uses within that area.

Impacts related to the extent of the area, the nature and degree, and types of land uses within the area were discussed previously and determined to be less than significant. Therefore, the project-related impacts to the extent of the area that would be affected, the nature and degree of impacts, and the type of land uses within that area would be **less than significant**, and no mitigation is required.

T-PLNG-5. The number, degree, and type of secondary impacts to surrounding land uses that could result from implementation of the Proposed Project.

The analysis contained in this EIR has determined that all operational impacts can be mitigated to less than significant levels with standard regulatory requirements or the implementation of mitigation measures (see Sections 3.1 through 3.11 of this EIR). Therefore, the number, degree, and type of secondary impacts to surrounding land uses that could result from implementation of the

Proposed Project would be **less than significant with application of standard regulatory requirements, project design low-impact development features, and mitigation measures MM AES-3, MM GEO-1, and MM NOI-3**, identified in this EIR**.**

3.8.4 Mitigation Measures

There are no mitigation measures required for the Proposed Project directly related to land use and planning. Secondary impacts to surrounding land uses that could result from construction of the Proposed Project are addressed with mitigation measures MM AES-1, MM AES-2, MM BIO-1 through MM BIO-9, MM CUL-1, MM NOI-1, MM NOI-2, and MM TRAF-1. Secondary impacts to land uses that could result from Proposed Project operations are addressed with mitigation measures MM AES-3, MM GEO-1, and MM NOI-3.

3.8.5 Significant Unavoidable Adverse Impacts

There are no direct significant unavoidable adverse impacts to land use and planning from implementation of the Proposed Project. However, secondary impacts to surrounding land uses related to construction noise and vibration are significant and unavoidable.

3.8.6 Cumulative Impacts

The Proposed Project area is comprised of built out urban land uses. The Proposed Project represents in-fill development within this existing environment and includes the construction of a public facility adjacent to the City's existing VPP. The related projects identified in Table 1-1, Related Projects List (see Chapter 1.0, Introduction of this EIR), primarily include infrastructure improvement projects, reflective of the built-out nature of the area. The cumulative projects identified would not result in cumulative impacts related to land use and planning since they do not entail new development that would conflict with the existing area uses. Similarly, the Proposed Project would represent a continuation of an existing use contained within a built-out area and which pre-dates the uses currently occupying the area. Given this, cumulative land use and planning impacts would be **less than significant**.

3.9 Noise and Vibration

3.9.1 Introduction

This section describes the potential noise and vibration impacts of the Proposed Project. It includes a discussion of existing regulatory requirements, the existing noise setting within the project area, and noise and vibration impacts that would result from implementation of the Proposed Project. Supporting technical information and analyses are hereby incorporated by reference and included as Appendix I [Noise Modeling Calculations] of this Environmental Impact Report (EIR).

As noted in the analysis below, impacts related to noise and vibration during construction activities would be significant and unavoidable, despite the application of mitigation measures.

During operation, impacts would also be significant. However, with incorporation of required mitigation measures, noise impacts during operation would result in less than significant impacts.

3.9.1.1 Noise Fundamentals

Noise is commonly defined as unwanted sound. Sound can be described as the mechanical energy of a vibrating object transmitted by pressure waves through a liquid or gaseous medium (e.g., air) to a hearing organ, such as a human ear. Noise is often defined as sound that is objectionable because it is disturbing or annoying.

In the science of acoustics, the fundamental model consists of a sound (or noise) source, a receptor, and the propagation path between the two. The loudness of the noise source and the obstructions or atmospheric factors, which affect the propagation path to the receptor, determine the sound level and the characteristics of the noise perceived by the receptor.

Continuous sound can be described by *frequency* (pitch) and *amplitude* (loudness). A low-frequency sound is perceived as low in pitch; a high-frequency sound is perceived as high-pitched. Frequency is expressed in terms of cycles per second, or Hertz (Hz) (e.g., a frequency of 250 cycles per second is referred to as 250 Hz). High frequencies are sometimes more conveniently expressed in kilohertz (kHz), or thousands of Hz. The audible frequency range for humans is generally between 20 Hz and 20,000 Hz. Very-low-frequency airborne sound of sufficient amplitude may be felt before it can be heard, and can be confused with ground-borne vibration.

The amplitude of pressure waves generated by a sound source determines the loudness of that source. As discussed in further detail below, the sound pressure level (also referred to simply as the sound level) is typically described in terms of decibels.

Decibels

The magnitude of a sound is typically described in terms of *sound pressure level* (SPL), which refers to the root-mean-square pressure of a sound wave and is measured in units called micropascals (µPa). One µPa is approximately one hundred-billionth (0.00000000001) of normal atmospheric pressure. Sound pressure amplitudes for different kinds of noise environments can range from less than 100 to over 100,000,000 µPa. Because of this large range of values, sound is rarely expressed in terms of µPa. Instead, a logarithmic scale is used to describe the sound pressure level in terms of

decibels, abbreviated dB. The decibel is a logarithmic unit that describes the ratio of the actual sound pressure to a reference pressure (20 µPa is the standard reference pressure level for acoustical measurements in air). Specifically, a sound pressure level, in decibels, is calculated as follows:

$$SPL = 20\log_{10}\left(\frac{X}{20\mu Pa}\right)$$

where *X* is the actual sound pressure and 20 µPa is the reference pressure. The threshold of hearing for young people is about 0 dB, which corresponds to 20 µPa.

Decibel Addition

Because decibels are logarithmic units, sound pressure levels cannot be added or subtracted through ordinary arithmetic. On the dB scale, a doubling of sound energy corresponds to a 3-dB increase. In other words, when two identical sources are each producing the same sound level, their combined sound level would be 3 dB higher than one source under the same conditions. For example, if one bulldozer produces a sound pressure level of 80 A-weighted decibels (dBA), two bulldozers would not produce 160 dBA; rather, they would combine to produce 83 dBA. The cumulative sound level of any number of sources, such as excavators, can be determined using decibel addition.

A-Weighting

The dB scale alone does not adequately characterize how humans perceive noise. The dominant frequencies of a sound have a substantial effect on the human response to that sound. Although the intensity (energy per unit area) of the sound is a purely physical quantity, the loudness or human response is determined by characteristics of the human ear.

Human hearing is limited in the range of audible frequencies as well as in the way it perceives the sound pressure level in that range. In general, people are most sensitive to the frequency range of 1,000 to 8,000 Hz and perceive sounds within that range better than sounds of the same amplitude in higher or lower frequencies. To approximate the response of the human ear, sound levels of individual frequency bands are weighted (i.e., adjusted), depending on human sensitivity to those frequencies. The resulting sound pressure level is expressed in A-weighted decibels or dBA.

The A-weighting scale approximates the frequency response of the average young ear when listening to most ordinary sounds. When people make judgments regarding the relative loudness or annoyance of a sound, their judgments correlate well with the A-weighted sound levels of those sounds. Table 3.9-1 describes typical A-weighted sound levels for various noise sources.

Table 3.9-1. Typical A-Weighted Sound Levels

Common Outdoor Noise Source	Sound Level (dBA)	Common Indoor Noise Source
	— 110 —	Rock band
Jet flying at 1,000 feet		
	— 100 —	
Gas lawn mower at 3 feet		
	— 90 —	
Diesel truck at 50 feet at 50 mph		Food blender at 3 feet
	— 80 —	Garbage disposal at 3 feet
Noisy urban area, daytime		
Gas lawn mower at 100 feet	— 70 —	Vacuum cleaner at 10 feet
Commercial area		Normal speech at 3 feet
Heavy traffic at 300 feet	— 60 —	
		Large business office
Quiet urban daytime	— 50 —	Dishwasher in next room
Quiet urban nighttime	— 40 —	Theater, large conference room (background)
Quiet suburban nighttime		
	— 30 —	Library
Quiet rural nighttime		Bedroom at night
	— 20 —	
		Broadcast/recording studio
	— 10 —	
Lowest threshold of human hearing	— 0 —	Lowest threshold of human hearing

Source: California Department of Transportation, 2013a.

Noise Descriptors

Because sound levels can vary markedly over a short period of time, a method for describing either the average character of the sound or the statistical behavior of the variations is utilized. Most commonly, environmental sounds are described in terms of the average level, or *equivalent sound level* (abbreviated L_{eq}), that describes the average acoustical energy content of noise for an identified period of time. Thus, the L_{eq} of a time-varying noise and that of a steady noise are the same if they deliver the same acoustical energy over the duration of the exposure. A common averaging period is hourly, but L_{eq} can describe any series of noise events of arbitrary duration. The scientific instrument used to measure noise is the sound level meter. Sound level meters can accurately measure environmental noise levels to within approximately plus or minus 1 dBA.

Additional commonly used noise metrics are described in Table 3.9-2 below, along with a summary of definitions of technical acoustical terms used in this section. Two of the metrics, Day/Night Noise Level (L_{dn}) and Community Noise Equivalent Level (CNEL), describe 24-hour average noise levels. When measured in typical outdoor environments, CNEL and L_{dn} are normally within 1 dBA of each other.

Table 3.9-2. Definitions of Acoustical Terms

Term	Definition
Decibel (dB)	A unit describing the amplitude of sound equal to 20 times the logarithm to base 10 of the ratio of the pressure of the sound measured to the reference pressure. The reference pressure for air is 20 µPa.
Sound Pressure Level	Sound pressure is the sound force per unit area, usually expressed in µPa (or micronewtons per square meter), where 1 pascal is the pressure resulting from a force of 1 newton exerted over an area of 1 square meter. The sound pressure level is expressed in decibels as 20 times the logarithm to base 10 of the ratio between the pressures exerted by the sound to a reference sound pressure (e.g., 20 µPa in air). Sound pressure level is the quantity that is measured directly by a sound level meter.
Frequency (Hz)	The number of complete pressure fluctuations per second above and below atmospheric pressure. Normal human hearing is between 20 Hz and 20,000 Hz. Infrasonic sounds are below 20 Hz, and ultrasonic sounds are above 20,000 Hz.
A-Weighted Sound Level (dBA)	The sound pressure level in decibels as measured on a sound level meter using the A weighting filter network. The A-weighting filter de-emphasizes the very low- and very high-frequency components of the sound in a manner similar to the frequency response of the human ear and correlates well with subjective reactions to noise.
Equivalent Sound Level (L_{eq})	The average A-weighted noise level during the measurement period. The hourly L_{eq} used for this report is denoted as dBA L_{eq}(h).
Community Noise Equivalent Level (CNEL)	The average A-weighted noise level during a 24-hour day, which is obtained by adding 5 dB to sound levels in the evening from 7 p.m. to 10 p.m., and 10 dB to sound levels between 10 p.m. and 7 a.m.
Day/Night Noise Level (L_{dn})	The average A-weighted noise level during a 24-hour day, which is obtained by adding 10 dB to sound levels measured at night between 10 p.m. and 7 a.m.
Percentile-Exceeded Sound Level (L_{XX})	The A-weighted noise level that is exceeded XX% of the time during the measurement period. E.g., L_{25} is the sound level exceeded 25% of the time, and L_{50} is the sound level exceeded 50% of the time.
Maximum Sound Level (L_{max})	The maximum sound level measured during the measurement period.
Minimum Sound Level (L_{min})	The minimum sound level measured during the measurement period.
Ambient Noise Level	The composite of noise from all sources near and far. The normal or existing level of environmental noise at a given location.

Source: ICF International, 2014.

Human Response to Noise

Studies have shown that under controlled conditions in an acoustics laboratory, a healthy human ear is able to discern changes in sound levels of 1 dBA. In the normal environment, the healthy human ear can detect changes of about 2 dBA; however, it is widely accepted that changes of 3 dBA in the normal environment are considered just noticeable to most people. A change of 5 dBA is readily perceptible, and a change of 10 dBA is perceived as being twice as loud. Accordingly, a doubling of sound energy (e.g., doubling the volume of traffic on a highway) resulting in a 3-dB increase in sound would generally be barely detectable.

Sound Propagation

When sound propagates over a distance, it changes in both level and frequency content. The manner in which noise is reduced with distance depends on the following important factors.

- **Geometric Spreading**. Sound from a single source (i.e., a "point" source) radiates uniformly outward as it travels away from the source in a spherical pattern. The sound level attenuates (or drops off) at a rate of 6 dBA for each doubling of distance. Highway noise is not a single stationary point source of sound. The movement of vehicles on a highway makes the source of the sound appear to emanate from a line (i.e., a "line" source) rather than from a point. This results in cylindrical spreading rather than the spherical spreading resulting from a point source. The change in sound level (i.e., attenuation or decrease) from a line source is 3 dBA per doubling of distance.
- **Ground Absorption**. Usually the noise path between the source and the observer is very close to the ground. The excess noise attenuation from ground absorption occurs due to acoustic energy losses on sound wave reflection. Traditionally, the excess attenuation has also been expressed in terms of attenuation per doubling of distance. This approximation is done for simplification only; for distances of less than 200 feet, prediction results based on this scheme are sufficiently accurate. For acoustically "hard" sites (i.e., sites with a reflective surface, such as a parking lot or a smooth body of water, between the source and the receptor), no excess ground attenuation is assumed because the sound wave is reflected without energy losses. For acoustically absorptive or "soft" sites (i.e., sites with an absorptive ground surface, such as soft dirt, grass, or scattered bushes and trees), an excess ground attenuation value of 1.5 dBA per doubling of distance is normally assumed. When added to the geometric spreading, the excess ground attenuation results in an overall drop-off rate of 4.5 dBA per doubling of distance for a line source and 7.5 dBA per doubling of distance for a point source.
- **Atmospheric Effects**. Research by the California Department of Transportation (Caltrans) and others has shown that atmospheric conditions can have a major effect on noise levels. Wind has been shown to be the single most important meteorological factor within approximately 500 feet, whereas vertical air temperature gradients are more important over longer distances. Other factors, such as air temperature, humidity, and turbulence, also have major effects. Receptors downwind from a source can be exposed to increased noise levels relative to calm conditions, whereas receptors upwind can have lower noise levels. Increased sound levels can also occur because of temperature inversion conditions (i.e., increasing temperature with elevation, with cooler air near the surface, where the sound source tends to be and the warmer air above acts as a cap, causing a reflection of ground level–generated sound).
- **Shielding by Natural or Human-Made Features**. A large object or barrier in the path between a noise source and a receptor can substantially attenuate noise levels at the receptor. The amount of attenuation provided by this shielding depends on the size of the object, proximity to the noise source and receptor, surface weight, solidity, and the frequency content of the noise source. Natural terrain features (such as hills and dense woods) and human-made features (such as buildings and walls) can substantially reduce noise levels. Walls are often constructed between a source and a receptor with the specific purpose of reducing noise. A barrier that breaks the line of sight between a source and a receptor will typically result in at least 5 dB of noise reduction. A higher barrier may provide as much as 20 dB of noise reduction.

3.9.1.2 Ground-borne Vibration Fundamentals

Ground-borne vibration is an oscillatory motion of the soil with respect to the equilibrium position and can be quantified in terms of *velocity* or *acceleration*. The velocity describes the instantaneous speed of the motion and acceleration is the instantaneous rate of change of the speed. Each of these measures can be further described in terms of *frequency* and *amplitude*. Typical outdoor sources of perceptible ground-borne vibration are heavy construction equipment (such as blasting and pile driving), railroad operations, and heavy trucks on rough roads. If a roadway is smooth, the ground-borne vibration from traffic is rarely perceptible. Ground-borne vibration can be a serious concern for neighbors of nearby sources, causing buildings to shake and rumbling sounds to be heard. Most perceptible indoor vibration is caused by sources within buildings, such as the operation of mechanical equipment, movement of people, or the slamming of doors.

Ground-borne vibration can be described in terms of peak particle velocity (PPV). PPV is defined as the maximum instantaneous positive or negative peak amplitude of the vibration velocity. The unit of measurement for PPV is inches per second (in/s). For transient vibration sources (single isolated vibration events such as blasting), the human response to vibration varies from barely perceptible at a PPV of 0.04 in/s, to distinctly perceptible at a PPV of 0.25 in/s, and severe at a PPV of 2.0 in/s. For continuous or frequent intermittent vibration sources (such as impact pile driving or vibratory compaction equipment), the human response to vibration varies from barely perceptible at a PPV of 0.01 in/s, to distinctly perceptible at a PPV of 0.04 in/s, and severe at a PPV of 0.4 in/s (California Department of Transportation 2013b). If a person is engaged in any type of physical activity, vibration tolerance increases considerably.

3.9.2 Regulatory Setting

3.9.2.1 State Regulations

California requires each local government entity to perform noise studies and implement a noise element as part of its general plan. The purpose of the noise element is to limit the exposure of the community to excessive noise levels; the noise element must be used to guide decisions concerning land use. The state provides guidelines for evaluating the compatibility of various land uses as a function of community noise exposure.

3.9.2.2 Local

City of Los Angeles CEQA Thresholds Guide

The *L.A. CEQA Thresholds Guide* (City of Los Angeles 2006) defines noise-sensitive land uses as residences, transient lodgings, schools, day-care facilities, libraries, churches, hospitals, nursing homes, auditoriums, concert halls, amphitheaters, playgrounds, and parks, and provides noise/land use compatibility guidelines, as summarized in Table 3.9-3.

Table 3.9-3. Land Use Noise Compatibility Guidelines

Land Use	Community Noise Exposure CNEL, dB			
	Normally Acceptable	Conditionally Acceptable	Normally Unacceptable	Clearly Unacceptable
Single-Family, Duplex, Mobile Homes	50–60	55–70	70–75	above 70
Multifamily Homes	50–65	60–70	70–75	above 70
Schools, Libraries, Churches, Hospitals, Nursing Homes	50–70	60–70	70–80	above 80
Transient Lodging – Motels, Hotels	50–65	60–70	70–80	above 80
Auditoriums, Concert Halls, Amphitheaters	—	50–70	—	above 65
Sports Arena, Outdoor Spectator Sports	—	50–75	—	above 70
Playgrounds, Neighborhoods Parks	50–70	—	67–75	above 72
Golf Courses, Riding Stables, Water, Recreation, Cemeteries	50–75	—	70–80	above 80

Normally Acceptable: Specified land use is satisfactory, based on the assumption that any buildings involved are of normal conventional construction and without any special noise insulation requirements.

Conditionally Acceptable: New construction or development should be undertaken only after a detailed analysis of the noise reduction requirements is made and needed noise insulation features included in the design. Conventional construction, but with closed windows and fresh air supply systems or air-conditioning, will normally suffice.

Normally Unacceptable: New construction or development generally should be discouraged. If new construction or development does proceed, a detailed analysis of the noise reduction requirements must be made and needed noise insulation features included in the design.

Clearly Unacceptable: New construction or development generally should not be undertaken.

Source: City of Los Angeles, 2006.

City of Los Angeles Municipal Code

Construction Noise

Section 41.40(a) of the City of Los Angeles Municipal Code prohibits the use, operation, repair, or servicing of construction equipment, as well as job-site delivery of construction materials, between the hours of 9:00 p.m. and 7:00 a.m. where such activities would disturb "persons occupying sleeping quarters in any dwelling hotel or apartment or other place of residence." Construction noise emanating from property zoned for manufacturing or industrial uses is exempted from the Section 41.40(a) standards. In addition, Section 41.40(c) prohibits construction, grading, and related job-site deliveries on or within 500 feet of land developed with residential structures before 8:00 a.m. or after 6:00 p.m. on any Saturday or national holiday or at any time on Sunday.

Section 112.05 of the municipal code places limits on the maximum noise levels (75 dBA at a distance of 50 feet for typical construction equipment) that may be produced by powered equipment or tools in, or within 500 feet of, any residential zone between the hours of 7 a.m. and 10 p.m. The proscribed limits shall not apply where compliance is technically infeasible but the

burden of proving that compliance is technically infeasible is on the person or persons charged with a violation of the standard. Technical infeasibility shall mean that the noise limit cannot be complied with despite the use of mufflers, shields, sound barriers, and/or other noise reduction devices or techniques during the operation of the equipment.

Operational Noise

Chapter XI, Noise Regulation, of the City of Los Angeles Municipal Code regulates noise from non-transportation noise sources such as commercial or industrial operations, mechanical equipment, or residential activities. It is noted that while these regulations do not apply to vehicles operating on public rights-of-way, they do apply to noise generated by vehicles on private property—such as truck operations at commercial or industrial facilities. The exact noise standards vary depending on the type of noise source, but the allowable noise levels are generally determined relative to the existing ambient noise levels at the affected location. Section 111.01(a) defines the ambient noise as "the composite of noise from all sources near and far in a given environment, exclusive of occasional and transient intrusive noise sources and of the particular noise source or sources to be measured. Ambient noise shall be averaged over a period of at least 15 minutes…" Section 111.03 provides minimum ambient noise levels for various land uses, as described in Table 3.9-4, below. In the event that the actual measured ambient level at the subject location is lower than that provided in the table, the level in the table shall be assumed.

Table 3.9-4. City of Los Angeles Assumed Minimum Ambient Noise Levels

	Assumed Minimum Ambient Noise (L_{eq}), dBA	
Zone	Daytime (7 a.m.–10 p.m.)	Nighttime (10 p.m.–7 a.m.)
A1, A2, RA, RE, RS, RD, RW1, RW2, R1, R2, R3, R4, and R5	50	40
P, PB, CR, C1, C1.5, C2, C4, C5, and CM	60	55
M1, MR1, and MR2	60	55
M2 and M3	65	65

Source: City of Los Angeles, 2013.

At the boundary line between two zones, the allowable noise level of the quieter zone shall be used. The allowable noise levels are then adjusted if certain conditions apply to the alleged offensive noise, as follows.

- For steady tone noise with an audible fundamental frequency or overtones (except for noise emanating from any electrical transformer or gas metering and pressure control equipment existing and installed prior to September 8, 1986) – reduce allowable noise level by 5 dBA.
- For repeated impulsive noise – reduce allowable noise level by 5 dBA.
- For noise occurring less than 15 minutes in any period of 60 consecutive minutes between the hours of 7:00 a.m. and 10:00 p.m. – increase allowable noise level by 5 dBA.

The City's noise ordinance is not explicit in defining the length of time over which an average noise level should be assessed. However, based on the noted reference to "60 consecutive minutes," above, it is inferred that the 1-hour L_{eq} metric should be used.

Section 112.02 of Chapter XI addresses noise from air conditioning, refrigeration, heating, pumping, and filtering equipment. It states that such equipment may not generate noise that would exceed the ambient noise level at any adjacent property by more than 5 dBA.

Section 114.02 of Chapter XI addresses noise from motor driven vehicles (it is noted that the code only addresses vehicles on private property and does not address vehicles while operated on public highways). It states that such vehicles may not generate noise that would exceed the ambient noise level at any occupied residential property by more than 5 dBA.

City of Los Angeles Noise Element

The Noise Element of the City's General Plan defines the following land uses to be noise-sensitive: single- and multi-family dwellings, long-term care facilities (including convalescent and retirement facilities), dormitories, motels, hotels, transient lodgings and other residential uses; houses of worship; hospitals; libraries; schools; auditoriums; concert halls; outdoor theaters; nature and wildlife preserves; and parks.

The Noise Element contains the following polices that are relevant to the Proposed Project.

Policy 5 – Continue to enforce, as applicable, City, state and federal regulations intended to abate or eliminate disturbances of the peace and other intrusive noise.

Policy 6 – When processing building permits, continue to require appropriate project design and/or insulation measures, in accordance with the California Noise Insulation Standards (Building Code Title 24, Section 3501 et seq.), or any amendments thereto or subsequent related regulations, so as to assure that interior noise levels will not exceed the minimum ambient noise levels, as set forth in the City's noise ordinance ([Los Angeles Municipal Code] Section 111 et seq., and any other insulation related code standards or requirements) for a particular zone or noise-sensitive use, as defined by the California Noise Insulation Standards.

Policy 11 – For a proposed development project that is deemed to have a potentially significant noise impact on noise-sensitive uses, as defined by this chapter, require mitigation measures, as appropriate, in accordance with California Environmental Quality Act and City procedures.

Policy 12 – When issuing discretionary permits for a proposed noise-sensitive use (as defined by this chapter) or a subdivision of four or more detached single-family units and which use is determined to be potentially significantly impacted by existing or proposed noise sources, require mitigation measures, as appropriate, in accordance with procedures set forth in the California Environmental Quality Act.

3.9.3 Environmental Setting

3.9.3.1 Existing Noise Environment

The primary existing noise sources in the project area are traffic on local streets, occasional aircraft overflights, and general neighborhood activities such as landscaping and home improvements. Noise from the existing Venice Pumping Plant (VPP) is also audible at the closest homes to that facility, which are approximately 50 to 80 feet to the west and south, on Hurricane Street and Canal Court.

The closest noise-sensitive receptors to the Project Site are residences (multi- and single-family) within approximately 15 feet of the Site. To the northwest, the Project Site is bounded by a neighboring residence. To the northeast, the site is bounded by a pedestrian/bike path and the Grand Canal, beyond which are existing homes along the east bank of the canal. To the southeast, the site is bounded by Hurricane Street, beyond which is the existing VPP; farther to the southeast are the Ballona Lagoon and more residences. To the southwest, the Project Site is bounded by Canal Court, beyond which are residences. Figure 2-2 (Chapter 2, Project Description) shows the Project Site and surrounding area.

Noise Monitoring

In order to determine the existing noise environment, measurements were obtained at five locations in the vicinity of the Project Site, as shown in Figure 3.9-1. One long-term (approximately 4 days) noise measurement (LT-1) was obtained at the northwest fence line of the Project Site. Short-term (ST) noise measurements (approximately 15 to 20 minutes) were obtained at four locations in the surrounding community. ST-1 was located approximately 70 feet northeast of the Project Site, across the Grand Canal; ST-2 was located approximately 20 feet southwest of the Project Site, across Canal Street; ST-3 was located approximately 100 feet south of the Project Site, across the intersection of Canal Street and Hurricane Street; and ST-4 was located approximately 400 feet southeast of the Project Site, across the Ballona Lagoon. The summary of the measurement results are provided in Tables 3.9-5 and 3.9-6. The long-term measurement was obtained between approximately 1:00 p.m. on Thursday, August 20, and 12:00 a.m. on Tuesday August 25, 2015. Short-term measurements were gathered on Thursday, August 20, and Tuesday August 25, 2015.

In addition to the noise measurements obtained directly for this noise analysis, ambient noise data were also supplied by the Proposed Project's design engineer (Arcadis 2015); the memo discussing these noise measurements is included in Appendix I. These data were gathered on Thursday, April 23, 2015, at locations very close to four of the measurement locations shown in Figure 3.9-1 and have also been added to Tables 3.9-5 and 3.9-6. The 24-hour CNEL noise levels for the locations monitored ranged from approximately 53 to 57 CNEL; daytime hourly average (one hour L_{eq}) noise levels ranged from approximately 45 to 66 dBA L_{eq} according to the long-term measurements, evening average noise levels ranged from approximately 47 to 52 dBA L_{eq}; and nighttime hourly average noise levels ranged from approximately 40 to 52 dBA L_{eq}. The L_{eq} values recorded during the short-term measurements ranged from approximately 50 to 53 dBA L_{eq} for ST-1, 48 to 50 dBA L_{eq} for ST-2, and 49 to 50 dBA L_{eq} for ST-3. The average noise level for ST-4 was approximately 51 dBA L_{eq}.

3.9.4 Environmental Impact Analysis

This section describes the methodology, evaluation, and impacts for temporary construction and permanent operational noise and vibration. This discussion is intended to assist in the evaluation and conclusions of the impact analysis provided below and in the formation of required mitigation measures.

3.9.4.1 Methodology

Noise Measurements

The long-term noise measurement of existing ambient noise levels was obtained using a Rion NL-21 Type 2 sound level meter. The short-term noise measurements of existing ambient noise levels and VPP equipment noise levels were obtained using Larson Davis 831 and LxT Type 1 sound level meters. The sound level meters were field calibrated for accuracy using a Larson Davis CAL200 acoustical calibrator.

Two measurements were obtained of equipment (pumps and motors) noise levels inside the existing VPP building, which is located southeast of the Project Site. The first measurement was taken in the VPP motor room, close to two motors that were running simultaneously. The microphone was located approximately 8 feet from the center axis of the first motor and 10.5 feet from the center axis of the second motor. At this location, the measured noise level (L_{eq}) was 83.6 dBA; this noise level included both direct noise from each motor and reverberant noise caused by sound reflected within the concrete-walled room.

The second measurement was taken in the VPP pump room, close to two pumps that were running simultaneously. The microphone was located approximately 11 feet from the center axis of the first motor and 12 feet from the center axis of the second motor. At this location the measured noise level (L_{eq}) was 83.8 dBA; this noise level included both direct noise from each pump and reverberant noise caused by sound reflected within the concrete-walled room.

Construction Noise and Vibration

Potential noise and vibration impacts associated with project construction activities were evaluated based on the Proposed Project's construction equipment schedule and phasing information.

Noise

Construction-related traffic noise was analyzed using calculations based on the Federal Highway Administration (FHWA) Traffic Noise Model (TNM) Version 2.5 Look-Up Tables (FHWA 2004). The inputs used in the traffic noise modeling included the estimated maximum daily truck trips specified in the Truck Traffic Analysis Data memo prepared for the project (Arcadis 2016a) and an assumed speed of 25 miles per hour on the local streets closest to the Project Site.

Construction-related noise was analyzed using data and modeling methodologies from FHWA's Roadway Construction Noise Model (RCNM) (FHWA 2006, 2008), which predicts average noise levels at nearby receptors by analyzing the type of equipment, the distance from source to receptor, usage factor, and the presence or absence of intervening shielding between source and receptor. This methodology calculates the composite average noise levels for multiple equipment items

scheduled during each construction phase. The source-to-receptor distances used in the analyses were the acoustical average distances between the relevant construction area and each receptor. The acoustical average distance is used to represent noise sources that are mobile or distributed over an area (such as the Project Site); it is calculated by multiplying the shortest distance between the receiver and the noise source area by the farthest distance and then taking the square root of the product. Noise levels for each phase of construction were analyzed at five receptors in the vicinity of the Project Site. These receptors are illustrated in Figure 3.9-2, and represent the closest noise-sensitive receptors (i.e., homes) in each direction from the Project Site. Table 3.9-7 provides the noise levels of construction equipment expected to be used by the Proposed Project; the noise levels are provided for a reference distance of 50 feet. Consistent with the RCNM methodology, it was assumed that construction noise levels would be reduced at a rate of 6 dB per doubling of distance from the source.

Table 3.9-7. Construction Equipment Noise Levels

Equipment Item	Maximum Noise Level (L_{max}) at 50 feet, dBA [a]	Usage Factor [a, b]	Average Noise Level (L_{eq}) at 50 feet, dBA
Excavator	80.7	0.4	77
Backhoe	77.6	0.4	74
Grader	85	0.4	81
Jack Hammer	88.9	0.2	82
Crane	80.6	0.16	73
Compactor	83.2	0.2	76
Pile Driver	101.3	0.2	94
Air Compressor	77.7	0.4	74
Concrete Trucks	81.4	0.2	74

Notes:

[a] Obtained or estimated from FHWA 2006, 2008 (RCNM).

[b] Usage Factor is the fraction of time the equipment is operating in its noisiest mode while in use. L_{eq} is estimated from L_{max} using the following equation: $L_{eq} = L_{max} + 10 \times \log_{10}$ (Usage Factor)

Source: ICF, 2015

Vibration

Construction-related vibration was analyzed using data and modeling methodologies provided by Caltrans' *Transportation and Construction Vibration Guidance Manual* (California Department of Transportation 2013b). This guidance manual provides typical vibration source levels for various types of construction equipment, as well as methods for estimating the propagation of ground-borne vibration over distance. Because potential vibration impacts are assessed based on peak levels, rather than long-term average levels, the source-to-receptor distances used in the analyses were the estimated range of distances (closest to farthest) between the relevant construction activity and each receptor. Table 3.9-8 provides the PPV levels of worst-case construction equipment expected to be used by the Proposed Project; the levels are provided for a reference distance of 25 feet.

K:\Irvine\GIS\Projects\LABOE\00476 15\mapdoc\Noise\Fig 3 9 2 Nois Analysis Locations.mxd Date: 10/5/2016 37937

Figure 3.9-2
Noise Analysis Locations
Venice Auxiliary Pumping Plant Project

Table 3.9-8. Construction Equipment Vibration Levels

Equipment Item	Reference PPV at 25 feet, in/s [a]
Pile driver	0.65
Large bulldozer[b]	0.089

Notes:
[a] Obtained from California Department of Transportation 2013b.
[b] Considered representative of other heavy earthmoving equipment such as excavators, graders, backhoes, etc.
Source: ICF, 2015

The following equations from the guidance manual were used to estimate the change in PPV levels over distance. For pile driving, the equation is:

$$PPV_{rec} = PPV_{ref} \times (25/D)^{n} \times (E_{equip}/E_{ref})^{0.5}$$

where PPV_{rec} is the PPV at a receiver; PPV_{ref} is the reference PPV at 25 feet from the pile driver (0.65 in/s); D is the distance from the pile driver to the receiver, in feet; n is a value related to the vibration attenuation rate through ground (the default recommended value for n is 1.1); E_{ref} is 36,000 foot-pounds (rated energy of reference pile driver); and E_{equip} is the rated energy of the actual impact pile driver in foot-pounds. (For the purposes of the analysis, it is assumed that the pile driver would be very similar to the reference pile driver and there would, therefore, be no adjustment for E_{equip}.)

For heavy earthmoving equipment such as excavators, graders, and backhoes, the equation is:

$$PPV_{rec} = PPV_{ref} \times (25/D)^{n}$$

where PPV_{rec} is the PPV at a receptor; PPV_{ref} is the reference PPV at 25 feet from the equipment (0.089 in/s); D is the distance from the equipment to the receiver, in feet; and n is a value related to the vibration attenuation rate through ground (the default recommended value for n is 1.1).

Operation

Potential noise and vibration impacts associated with project operations were evaluated based primarily on information provided in the project's *Preliminary Design Report* (PDR) (Arcadis 2016b). This information included the general project description, preliminary plans, and preliminary specifications for equipment at VAPP that would generate noise. For some equipment, noise data were provided within the PDR; for other equipment representative or additional noise data were obtained from publicly available manufacturers' specifications or predicted using published algorithms (Barron 2003). It was assumed that noise levels would be reduced at a rate of 6 dB per doubling of distance from the source and the noise levels at sensitive receptors were estimated using standard decibel calculations, including the following.

1. To calculate the change in sound level due to a change in the number of identical equipment items operating:

   $$\Delta = 10 \times \log_{10} (A/B)$$

   where Δ is the change in total noise level in dB; A is the new number of equipment items; and B is the new number of equipment items.

2. To calculate a sound pressure level from a stated sound power level:

   $SPL = SWL + DI - 20 \times \log_{10} (D) - 10.9$ (Barron 2003)

   where SPL is the resulting sound pressure level in dB; SWL is the stated sound power level in dB; DI is the directivity index (with a value of 3 for hemispherical spreading across the ground); and D is the distance from the noise source in feet.

3. To calculate the change in sound pressure level with distance:

   $SPL_{rec} = SPL_{ref} + 20 \times \log_{10} (D_{ref}/D_{rec})$

   where SPL_{rec} is the sound pressure level, in dB, at a receiver; SPL_{ref} is the sound pressure level, in dB, at a reference distance; D_{ref} is the reference distance, in feet, from the noise source; and D_{rec} is the receiver distance, in feet, from the noise source.

Screening Analysis

As noted in Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in Appendix G of the CEQA Guidelines and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.9.4.2 Thresholds of Significance

Appendix G of the *State CEQA Guidelines* provides six criteria, in the form of checklist questions a through e, that can be used to assess the significance of potential noise and vibration impacts. For some (but not all) of these criteria, the *L.A. CEQA Thresholds Guide* provides additional guidance on how potential impacts should be quantified or assessed. Where specific guidance is provided by the *L.A. CEQA Thresholds Guide*, those thresholds have been used as the basis for assessment of project impacts. For the any remaining criteria, the checklist questions provide the basis of the analysis, with specific thresholds developed, as necessary, from alternate sources as described below.

State CEQA Guidelines, Appendix G

The six checklist questions related to potential noise impacts are listed below, followed by a discussion of how each is addressed in this EIR.

Would the project result in:

NOI-1. Exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

NOI-2. Exposure of persons to or generation of excessive ground-borne vibration or ground-borne noise levels?

NOI-3. A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?

NOI-4. A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?

NOI-5. For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?

NOI-6. For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?

To address checklist questions NOI-1, NOI-3, and NOI-4, the *L.A. CEQA Thresholds Guide* provides separate criteria for construction noise and operational noise; these criteria are described below and are used in place of checklist questions NOI-1, NOI-3, and NOI-4 to address potential construction and operational noise impacts. Checklist question NOI-2 does not quantify what would constitute excessive ground-borne vibration or ground-borne noise levels, and the *L.A. CEQA Thresholds Guide* does not provide any vibration criteria; therefore, thresholds for this potential impact have been developed based on guidance from Caltrans, as described below. As discussed above, Project implementation would result in no noise impacts related to airports or airstrips, so these issue areas are not included in this analysis and no further discussion of checklist questions NOI-5 or NOI-6 is provided.

City of Los Angeles CEQA Thresholds Guide

Construction Noise

The following threshold of significance for construction noise is based on the *L.A. CEQA Thresholds Guide* (2006).

The project would have a significant construction noise impact if:

NOI-7. Construction activities lasting more than 1 day would exceed existing ambient exterior noise levels by 10 dBA or more at a noise-sensitive use;

NOI-8. Construction activities lasting more than 10 days in a 3-month period would exceed existing ambient exterior noise levels by 5 dBA or more at a noise-sensitive use; or

NOI-9. Construction activities would exceed the ambient noise level by 5 dBA at a noise-sensitive use between the hours of 9:00 p.m. and 7:00 a.m. Monday through Friday, before 8:00 a.m. or after 6:00 p.m. on Saturday, or at any time on Sunday.

Proposed CEQA Threshold for Vibration

The *L.A. CEQA Thresholds Guide* (2006) does not include thresholds for vibration impacts. Because project construction would generate ground-borne vibration, the City uses guidance from Caltrans' *Transportation and Construction Vibration Guidance Manual* (California Department of Transportation 2013b) to determine the threshold of impact for vibration. Guidelines are provided for two types of potential impact: (1) damage to structures, and (2) annoyance of people. Guideline criteria for each are provided in Tables 3.9-9 and 3.9-10.

Table 3.9-9. Caltrans Guideline Vibration Damage Criteria

	Maximum PPV (in/s)	
Structure and Condition	Transient Sources	Continuous/Frequent Intermittent Sources
Extremely fragile historic buildings, ruins, ancient monuments	0.12	0.08
Fragile buildings	0.2	0.1
Historic and some old buildings	0.5	0.25
Older residential structures	0.5	0.3
New residential structures	1.0	0.5
Modern industrial/commercial buildings	2.0	0.5

Notes:
Transient sources create a single isolated vibration event, such as blasting or drop balls. Continuous/frequent intermittent sources include impact pile drivers, pogo-stick compactors, crack-and-seat equipment, vibratory pile drivers, and vibratory compaction equipment.
Source: California Department of Transportation, 2013b.

Table 3.9-10. Caltrans Guideline Vibration Annoyance Criteria

	Maximum PPV (in/s)	
Human Response	Transient Sources	Continuous/Frequent Intermittent Sources
Barely perceptible	0.04	0.01
Distinctly perceptible	0.25	0.04
Strongly perceptible	0.9	0.10
Severe	2.0	0.4

Notes:
Transient sources create a single isolated vibration event, such as blasting or drop balls. Continuous/frequent intermittent sources include impact pile drivers, pogo-stick compactors, crack-and-seat equipment, vibratory pile drivers, and vibratory compaction equipment.
Source: California Department of Transportation, 2013b.

The construction equipment used at the Project Site would fall into the *continuous/frequent intermittent sources* category. Based on these guidelines, the following thresholds will be used to assess potential vibration impacts:

NOI-11. The project would have a significant vibration impact, relative to potential building damage, if NOI-13. PPV vibration levels from construction equipment are 0.3 in/s or greater at any existing residential structure, or 0.5 in/s at the adjacent VPP structure.

NOI-12. The project would have a significant vibration impact, relative to potential annoyance, if NOI-15. PPV vibration levels from construction equipment are 0.04 in/s or greater (distinctly perceptible) at any existing residence.

Operational Noise

The following threshold of impact for operational noise is based on the *L.A. CEQA Thresholds Guide* (2006).

NOI-13. The project would have a significant operational noise impact if it causes:

- The ambient noise level measured at the property line of affected uses to increase by 3 dBA in CNEL to or within the "normally unacceptable" or "clearly unacceptable" categories, or any 5 dBA or greater noise increase (refer to Table 3.9-3, above).

For residences this means a significant impact would occur if the project caused the ambient noise level to increase by 3 dB or more to 70 dB CNEL or greater, or to increase by 5 dB or more to less than 70 dB CNEL.

3.9.4.3 Construction Impacts

The analysis below describes the temporary impacts related to noise and vibration as a result of the Proposed Project during construction.

NOI-1: Would project construction noise exceed any of the construction noise criteria provided by the L.A. CEQA Thresholds Guide (i.e., exceed existing ambient exterior noise levels by 10 dBA or more at a noise-sensitive use for activities lasting more than 1 day; or exceed existing ambient exterior noise levels by 5 dBA or more at a noise-sensitive use for construction activities lasting more than 10 days in a 3-month period, or activities occurring between the hours of 9 p.m. and 7 a.m. Monday through Friday, before 8 a.m. or after 6 p.m. on Saturday, or at any time on Sunday?

Two types of short-term noise impacts could occur during construction of the Proposed Project. The first would be related to construction traffic—construction workers who commute to the site and trucks that transport equipment and materials. The second would be on-site construction activities at the Project Site and loading/unloading activities at the three proposed construction laydown areas (see Figure 2-2 in Chapter 2, Project Description).

Construction traffic would incrementally increase noise levels on access roads, including Pacific Avenue, Via Dolce, and Canal Court. Construction workers would be required to park off site and then travel to and from the site by shuttle, which would serve to minimize the number of vehicle trips on local streets to and from the Project Site. No construction worker parking would be allowed along Hurricane Street or on adjacent streets. Although there would be a relatively high single-event noise level, which could cause an intermittent noise nuisance (e.g., passing trucks at 50 feet would generate up to 76 dBA), the contribution of construction traffic to ambient noise levels (such as the daily CNEL) would be low due to the infrequent traffic volume. Based on data provided by the Project Engineer (Fehr & Peers 2016)[1], there could be up to 24 trucks per day to haul soil to or from the site. To provide a conservative analysis, it was assumed that each truck could travel on the same roadway twice during a round trip (for a total of 48 individual trips). The analysis indicates these truck trips would generate a noise level of up to 52 dB CNEL at the homes adjacent to access roads

[1] Fehr & Peers. 2016. *Trip Generation Analysis – Venice Auxiliary Pumping Plant Project.* LA15-2780.00. Los Angeles, CA..

(refer to Appendix I of this EIR for additional details). This is below the range of existing noise levels measured in the surrounding community (53 to 57 dB CNEL). Therefore, construction traffic would not increase ambient noise levels by 3 dB CNEL or more. As a result, short-term impacts associated with construction-related traffic driving to and from the Project Site would be less than significant and no mitigation is required.

Construction of the Proposed Project is anticipated to begin in March 2018 and last approximately 2 years. Day-to-day construction activities would vary throughout the construction process and would cease once construction of the Proposed Project is completed. In accordance with the City of Los Angeles Municipal Code, construction would not take place outside the hours of 7 a.m. to 9 p.m. Monday through Friday, or 8 a.m. to 6 p.m. on Saturdays or national holidays. Typical work hours would be 8 a.m. to 6 p.m., Monday through Saturday. Project construction would be broken down into phases. The phases of construction (see also Chapter 2, Project Description) and anticipated construction equipment for each are summarized in Table 3.9-11.

Table 3.9-11. Construction Phasing and Equipment Items

Construction Phase	Equipment Item(s)
Demolition	Excavator
	Backhoe
	Grader
	Jack Hammer
Site Preparation	Excavator

	Excavator
	Concrete Trucks (2)

Source: Arcadis, 2015.

Based on this information, average hourly noise levels (i.e., 1-hour L_{eq}) were estimated for each phase of construction at each of the five receptors considered in the analysis (refer to Figure 3.9-2). For the building construction phase, noise levels were estimated both with and without pile driving. This is because pile driving would generally dominate the construction noise levels when it occurs, but would not occur throughout the entire phase. As such, noise levels and the associated potential impacts would be noticeably different with and without pile driving, and it is informative to examine both cases. Detailed calculations are provided in Appendix I of this EIR. The results of the analyses are summarized in Table 3.9-12, below, and show that noise levels could be up to 98 dBA L_{eq} at the nearest sensitive receptor during construction activities that involve pile driving, and up to 89 dBA L_{eq} at the nearest sensitive receptor during construction activities that do not involve pile driving. The table also indicates the average weekday daytime ambient noise levels at each receptor based

on the noise measurements summarized in Tables 3.9-5 and 3.9-6. Note that ambient noise levels range from 50 to 54 dBA L_{eq}. Because construction would last for more than 10 days in a 3-month period, a significant impact would occur if construction noise levels were to exceed the existing ambient exterior noise levels by 5 dBA or more at a noise-sensitive use.

Source: ICF, 2015.

Referring to Table 3.9-12, this condition would occur under all the analyzed scenarios for all receptors except for building construction (no pile driving) noise levels at Receptor 5. As shown in this table, construction noise increases over ambient noise levels range from 4 to 46 dB. While implementation of **Mitigation Measure (MM) NOI-1**, requires a construction noise control plan and includes a list of measures that would reduce construction noise, (see Section 3.9.5) impacts would not be completely eliminated. Even with implementation of the measures listed in **MM NOI-1**,

construction activities are anticipated to result in noise levels that increase the ambient noise levels by more than 5 dB and; therefore, **construction noise impacts would remain significant and unavoidable**.

Intermittent construction-related noise would also be generated by activities at nearby storage/laydown areas outside the Project Site at vacant lots adjacent to the Grand Canal (off Via Dolce, Laydown Area 2), Ballona Lagoon (128 Hurricane Street, Laydown Area 1), and in Culver City (9940 Jefferson Boulevard, Laydown Area 3). While these activities would likely be audible at neighboring noise-sensitive receptors and may cause annoyance, they would only occur sporadically and for a limited duration. **MM NOI-1**, which requires a construction noise control plan and includes a list of measures that would help reduce construction-generated noise, (see Section 3.9.5) would help to minimize noise levels from the storage/laydown areas at noise-sensitive receptors. As no noise sensitive land uses are located in close proximity to Laydown Area 3, noise impacts from the activities would be less than significant. Noise impacts at Laydown Areas 1 and 2 would be **reduced with implementation of MM NOI-1; however, overall construction activities would still result in a significant and unavoidable impact**.

NOI-2 and NOI-3: Would project construction result in groundborne vibration levels that are distinctly perceptible at a receiving residential use, or could potentially result in building damage?

Referring to the equipment schedule provided above in Table 3.9-11, various pieces of heavy equipment such as graders and excavators would be used at the Project Site, as well as pile driving equipment. Vibration levels (PPV, in/s) were estimated for each phase of construction at each of the five receptors considered in the analysis (refer to Figure 3.9-2), as well as the existing VPP structure, using the methodology described in Section 3.9.4.1. For the building construction phase, vibration levels were estimated both with and without pile driving because pile driving would generally dominate the vibration levels when it occurs, but would not occur throughout the entire phase (it is estimated that a total of up to 30 days of project construction would include pile driving). As such, vibration levels and the associated potential impacts would be noticeably different with and without pile driving, and it is informative to examine both cases. In accordance with the City of Los Angeles Municipal Code, construction activities, including pile driving, would not take place outside the hours of 7 a.m. to 9 p.m. Monday through Friday, or 8 a.m. to 6 p.m. on Saturdays or national holidays. Typical work hours would be 8 a.m. to 6 p.m., Monday through Friday. **MM NOI-1** restricts pile driving, excavation, and jackhammer activities to 9 am to 3:30 pm, Monday through Saturday.

Detailed vibration calculations are provided in Appendix I of this EIR. The results of the analyses are summarized in Table 3.9-13, below as a range of vibration levels based on the estimated range of distances from each receiver that would occur as construction activity shifts around the Project Site and impacts are assessed relative to the highest PPV. Modeling results generally show that vibration levels from building construction with pile driving would exceed the annoyance threshold (distinctly perceptible vibration of 0.04 in/s for the continuous/frequent intermittent sources) for vibration at receptors 1, 2, 3, and 4. Vibration levels from demolition, site preparation, grading, building construction without pile driving, and paving would exceed the annoyance thresholds at receptors 2 and 3. Vibration levels from building construction with pile driving would exceed the potential damage thresholds (0.3 in/s at homes and 0.5 in/s at VPP) at receptors 1, 2, and 3, and at the existing VPP structure; however, no other construction activities would result in exceedance of the potential damage threshold.

Table 3.9-13. Estimated Construction Vibration Levels

Source: ICF, 2015

Referring to the table, groundborne vibration from construction, including both pile driving and other construction activities, would exceed the thresholds developed for potential annoyance at nearby homes; ground-borne vibration from pile driving activities would exceed the thresholds developed for potential vibration damage at nearby structures. **MM NOI-2**, which requires the implementation of strategies to reduce construction-related vibration effects (the use of alternative pile driving methods, pre-construction surveys of adjacent structures, and possible monitoring during construction), would reduce construction vibration effects related to both of the thresholds. Impacts related to the threshold associated with potential building damage would be reduced to **less than significant with implementation of MM NOI-2**. Impacts related to the threshold associated with annoyance from distinctly perceptible vibration cannot be completely eliminated and vibration levels would remain distinctly perceptible at

residential buildings within approximately 52 feet of heavy construction equipment even after implementation of **MM NOI-1** and **MM NOI-2**; therefore, **this impact would remain significant and unavoidable.**

3.9.4.4 Operational Impacts

The analysis below describes the anticipated permanent impacts related to noise and vibration as a result of the Proposed Project during operation.

NOI-3 and NOI-4: Would project operational noise exceed the operational noise criteria provided by the L.A. CEQA Thresholds Guide (i.e., cause the ambient noise level measured at the property line of affected uses to increase by 3 dB CNEL to or within the "normally unacceptable" or "clearly unacceptable" categories, or any 5 dBA or greater noise increase)?

Once completed, VAPP would contain a number of equipment items and systems that would generate noise during operation. The primary noise sources would include the following:

- **Three submersible pumps, with associated electrical motors and variable frequency drives**. Each pump would have a design capacity of 18 million gallons per day and each pump, motor, and variable frequency drive would have a nominal power rating of 500 horsepower (HP). These pumps would be below ground and installed in a subterranean vault with sealed access hatches.
- **Heating, ventilation, and air conditioning (HVAC) equipment**. A 20-ton year-round cooling and ventilation unit is proposed for the first floor of the electrical building. A 5-ton heat pump is proposed for the second floor of the electrical building. The office and the mechanical room would each have a 40-cubic-feet-per-minute ventilation fan, and the bathroom would be provided with a 140-cubic-feet-per-minute exhaust fan. The cooling and ventilation unit and the heat pump would be outside the building; the exhaust fans would be inside the building or on the rooftop.
- **An emergency generator**. A 24-kilowatt (kW) diesel generator inside the electrical building would provide backup power to VAPP critical loads in the event of loss of power from the Los Angeles Department of Water and Power. The generator would provide 24 kW of power at 120/240 volts (V) for lighting and other support systems such as security and access control, and air conditioning. (This generator would not be of sufficient size to power the pumps within VAPP; standby power for pumps at VAPP would be provided by the existing 750-kW to 1,500-kW diesel generators at VPP.)
- **Two new 34.5 kV – 480 V pad-mounted type transformers** installed on existing exterior ground floor pads and connected to Los Angeles Department of Water and Power electrical power lines.

Potential noise levels generated by each of these sources are discussed below.

Pumps

In order to estimate noise levels from the proposed pumps, noise measurements were obtained at the existing VPP. The pumps and motors operating during these measurements were slightly smaller than the proposed VAPP equipment (400 HP versus 500 HP) but had the same nominal design capacity of 18 million gallons per day. Therefore, the noise levels are expected to be similar.

As noted previously (see Section 3.9.4.1, *Methodology*), noise measurements at the existing VPP indicate interior noise levels of 83.6 dBA for two motors running simultaneously and 83.8 dBA for two pumps running simultaneously. The average distance to the noise sources during the measurements was approximately 10 feet. At VAPP, up to three pumps and motors are expected to run simultaneously under worst-case conditions (only during extreme wet-weather conditions or in the event that service or maintenance of pumps at the VPP is required). In this condition, an overall noise level increase of 1.8 dB relative to two pumps and motors running would result. Furthermore, the pumps and motors at VAPP would be located in the same subterranean vault, resulting in a total estimated noise level of approximately 89 dBA L_{eq} within the vault. If the equipment were to run for 24 hours, this would equate to approximately 95 dB CNEL. In order to avoid increasing ambient noise levels by more than 5 dB CNEL, the noise levels would have to be reduced to less than 56 dB CNEL (based on the measured ambient CNEL of 53 dB). Adjusting for the distance from the pumps and motors to the closest noise-sensitive receptor (the residence approximately 32 feet to the northwest) the noise level would be reduced by approximately 10 dB[2] to 85 dB CNEL. The pumps and motors would also be enclosed within a concrete vault, which can reasonably be assumed to reduce noise levels by at least 20 dB (Caltrans 2013) resulting in a noise level of 65 dB CNEL. This would increase ambient noise levels by more than 5 dB CNEL, which would be a significant impact. **MM NOI-3**, which requires final design of the Project to limit noise increases and ensure that all mechanical and electrical equipment noise levels comply with the City of Los Angeles Municipal Code, would reduce noise impacts to **less-than-significant with incorporation of mitigation measures**.

HVAC Equipment

Noise levels for the proposed 20-ton cooling and ventilation unit were obtained from manufacturer's data for the unit specified in the PDR (Arcadis 2016b; Mitsubishi Electric Corporation 2014). The data indicate an overall noise level of 63 dBA at a distance of 1 meter (3.3 feet) from the side of the unit; based on the published dimensions of the unit, this equates to an acoustical average distance of approximately 5.2 feet. Published data for a 5-ton heat pump (Ingersoll-Rand 2015) indicate a sound power level of up to 75 dBA. Normalizing these source data to a reference distance of 50 feet gives reference noise levels of 43.3 dBA[3] and 43.4 dBA,[4] respectively, for the two units. Based on preliminary design plans, the HVAC units would be located on an exterior ground-floor pad adjacent to the northwest facade of the electrical building. The anticipated noise levels from the mechanical room and bathroom ventilation fans would be minimal in the surrounding community due to the relatively small size of the fans and because they would typically vent through the roof of the electrical building, where they would be shielded from neighboring properties. Based on the described assumptions and data, Table 3.9-14 summarizes the estimated noise levels at each of the five sensitive receptors considered in the analysis (refer to Figure 3.9-2). The table also indicates the combined HVAC noise level, the estimated CNEL that would occur if the equipment was to run continuously for 24 hours, a comparison to existing ambient noise levels, and the assessment of impact. The analysis indicates that HVAC noise levels would range from approximately 34 to 66 dB CNEL at the closest sensitive receptors, and would increase the overall CNEL by between 0 and 13 dB.

[2] $20 \times \log_{10} (10/32) = 10.1$

[3] $63 \text{ dBA} + 20 \times \log_{10} (5.2/50) = 43.3 \text{ dBA}$

[4] $75 \text{ dBA} + 3 - 20 \times \log_{10} (50*0.3048) - 0.6 = 43.4 \text{ dBA}$

Table 3.9-14. Estimated HVAC Noise Levels

Equipment Item/ Noise Source	Reference L_{eq} @ 50'	Noise Level at Closest Sensitive Receptors, dBA (distance, feet)				
		Receptor 1 (140 feet)	Receptor 2 (12 feet)	Receptor 3 (50 feet)	Receptor 4 (150 feet)	Receptor 5 (480 feet)
20-ton cooling and ventilation unit	43.3 dBA	34.4 dBA L_{eq}	55.7 dBA L_{eq}	43.3 dBA L_{eq}	33.8 dBA L_{eq}	23.7 dBA L_{eq}
5-ton heat pump	43.4 dBA	34.5 dBA L_{eq}	55.8 dBA L_{eq}	43.4 dBA L_{eq}	33.9 dBA L_{eq}	23.8 dBA L_{eq}
Combined HVAC noise level, dBA L_{eq}	46.4 dBA	37.5 dBA L_{eq}	58.8 dBA L_{eq}	46.6 dBA L_{eq}	36.9 dBA L_{eq}	26.8 dBA L_{eq}
Combined HVAC CNEL, dB[a]	N/A	44.2 dB CNEL	65.5 dB CNEL	53.1 dB CNEL	43.6 dB CNEL	33.5 dB CNEL
Existing Ambient CNEL	N/A	57 dB CNEL	52.8–56.5 dB CNEL	56 dB CNEL	56 dB CNEL	57 dB CNEL
Total CNEL (HVAC + Ambient)	N/A	57.2 dB CNEL	65.7–66.0 dB CNEL	57.8 dB CNEL	56.2 dB CNEL	57.0 dB CNEL
Increase over ambient CNEL	N/A	0.2 dB	9.5–12.9 dB	1.8 dB	0.2 dB	0 dB
Significant impact	N/A	No	Yes	No	No	No

Notes:
[a] Assumes equipment runs 24 hours per day
Source: ICF International, 2016.

Referring to the results of the analysis, HVAC noise is anticipated to increase ambient noise levels at Receptor 2 by more than 5 dB CNEL, which would be a potentially significant impact. However, with implementation of MM NOI-3, which requires final design of the Project to limit noise increases and ensure that all mechanical and electrical equipment noise levels comply with the City of Los Angeles Municipal Code, this significant impact would be reduced to a **less-than-significant level with incorporated mitigation measures**.

Emergency Generator

The new 24-kW standby generator, used to provide critical backup power in the event of loss of power from LADWP, would be housed inside of the proposed electrical building. Based on preliminary design plans in the PDR (Arcadis 2016b), the generator room would be on the first floor, at the southeast corner of the building. Noise levels for the generator were obtained from manufacturer's data for the unit specified in the PDR (Kohler Power Systems 2014). The manufacturer's data indicate an overall noise level of 66 dBA at a distance of 23 feet from the unit when installed with the manufacturer's sound-attenuating housing; this reference noise level was utilized to calculate estimated noise levels at the nearest noise-sensitive receptors. Table 3.9-15 summarizes the estimated noise levels at each of the five sensitive receptors considered in the analysis; these values do not account for the sound-attenuating benefits of enclosing the generator inside the building, which is a conservative approach. The table also indicates the estimated CNEL that would occur if the generator was to run continuously for 24 hours, a comparison to existing ambient noise levels, and the assessment of impact. The analysis indicates that generator noise

levels would range from approximately 47 to 65 dB CNEL at the closest sensitive receptors, and would increase the overall CNEL by between 0 and 11 dB.

Table 3.9-15. Estimated Standby Generator Noise Levels

Equipment Item/ Noise Source	Reference L_{eq} @ 23'	Noise Level at Closest Sensitive Receptors, dBA (distance, feet)				
		Receptor 1 (145 feet)	Receptor 2 (65 feet)	Receptor 3 (55 feet)	Receptor 4 (125 feet)	Receptor 5 (440 feet)
24-kW standby generator	66 dBA	50.0 dBA L_{eq}	57.0 dBA L_{eq}	58.4 dBA L_{eq}	51.3 dBA L_{eq}	40.4 dBA L_{eq}
Generator CNEL, dB[a]	N/A	56.7 dB CNEL	63.7 dB CNEL	65.1 dB CNEL	58.0 dB CNEL	47.1 dB CNEL
Existing Ambient CNEL	N/A	57 dB CNEL	52.8–56.5 dB CNEL	56 dB CNEL	56 dB CNEL	57 dB CNEL
Total CNEL (HVAC + Ambient)	N/A	59.9 dB CNEL	64.0–64.4 dB CNEL	65.6 dB CNEL	60.1 dB CNEL	57.4 dB CNEL
Increase over ambient CNEL	N/A	2.9 dB	7.9–11.2 dB	9.6 dB	4.1 dB	0.4 dB
Significant impact	N/A	No	Yes	Yes	No	No

Notes:
[a] Assumes equipment runs 24 hours per day
Source: ICF International, 2016.

Based on the results of the analysis, there is the potential for significant noise impacts (increases in ambient noise levels of 5 dB CNEL or more) associated with operation of the emergency generator. This significant impact could extend up to approximately 105 feet from the emergency generator. The electrical building would be required to provide approximately 8 dB of noise attenuation to eliminate impacts on nearby sensitive receptors (i.e., to reduce the resulting noise increases to less than 5 dB CNEL). **MM NOI-3**, which requires final design of the Project to limit noise increases and ensure that all mechanical and electrical equipment noise levels comply with the City of Los Angeles Municipal Code, would reduce noise impacts to **less-than-significant with incorporation of mitigation measures**.

Electrical Transformers

Noise levels for the proposed new electrical transformers were estimated assuming they would have a similar power rating to the existing VPP transformers, which are rated at 1,500 thousand volt-amps (kVA). Using published prediction algorithms (Barron 2003), the sound power level of each transformer was estimated to be 76 dBA. Normalizing this source level to a reference distance of 50 feet gives a reference noise level of 41.4 dBA[5] for each transformer. Based on preliminary design plans, the transformers would be located on exterior ground-floor pads between the southwest facade of the electrical building and the southwest project property line. Based on the described assumptions and data, Table 3.9-16 summarizes the estimated noise levels at each of the five sensitive receptors considered in the analysis (refer to Figure 3.9-2) due to the operation of the two transformers. The table also indicates the estimated CNEL that would occur if the transformers were to run continuously for 24 hours, a comparison to existing ambient noise levels, and the assessment

[5] 76 dBA - 20 × $\log_{10}$ (50) – 0.6 = 41.4 dBA

of impact. The analysis indicates that transformer noise levels would range from approximately 25 to 49 dB CNEL at the closest sensitive receptors, and would increase the overall CNEL by between 0 and 4 dB. Referring to the results of the analysis, transformer noise is not anticipated to increase

Table 3.9-16. Estimated Transformer Noise Levels

Equipment Item/Noise Source	Reference L_{eq} @ 50'	Noise Level at Closest Sensitive Receptors, dBA (distance, feet from each transformer)				
		Receptor 1 (165', 165')	Receptor 2 (27', 56')	Receptor 3 (28', 28')	Receptor 4 (110', 130')	Receptor 5 (440', 475')
1,500 kVA transformer	41.4 dBA	31.0 dBA L_{eq}	46.8 dBA L_{eq}	46.4 dBA L_{eq}	34.6 dBA L_{eq}	22.5 dBA L_{eq}
1,500 kVA transformer	41.4 dBA	31.0 dBA L_{eq}	40.4 dBA L_{eq}	46.4 dBA L_{eq}	33.1 dBA L_{eq}	21.8 dBA L_{eq}
Combined Transformer noise level, dBA L_{eq}	N/A	34.0 dBA L_{eq}	47.7 dBA L_{eq}	49.4 dBA L_{eq}	36.9 dBA L_{eq}	25.2 dBA L_{eq}
Combined HVAC CNEL, dB[a]	N/A	40.7 dB CNEL	54.4 dB CNEL	56.1 dB CNEL	43.6 dB CNEL	31.9 dB CNEL
Existing Ambient CNEL	N/A	57 dB CNEL	52.8–56.5 dB CNEL	56 dB CNEL	56 dB CNEL	57 dB CNEL
Total CNEL (HVAC + Ambient)	N/A	57.1 dB CNEL	56.7–58.6 dB CNEL	59.1 dB CNEL	56.2 dB CNEL	57.0 dB CNEL
Increase over ambient CNEL	N/A	0.1 dB	2.1–3.9 dB	3.1 dB	0.2 dB	0 dB
Significant impact	N/A	No	No	No	No	No

Notes:

ambient noise levels at any sensitive receptor by 5 dB CNEL or more. However, transformer noise would contribute to the overall operational noise levels for the facility, which are identified elsewhere in this section as being potentially significant. **MM NOI-3**, which requires final design of the project to limit noise increases and ensure that all mechanical and electrical equipment noise levels comply with the City of Los Angeles Municipal Code, would reduce operational noise impacts to **less-than-significant with incorporation of mitigation measures**.

In addition to the various noise sources discussed above, some noise would be generated by the parking for the Proposed Project that would be provided on the 128 Hurricane Street lot. While sporadic noise would be audible at neighboring properties, the overall level and nature of the noise would be similar to that of the street parking activity that currently occurs in the neighborhood, Therefore, future operation of 128 Hurricane Street as a parking lot would not lead to a noticeable increase in ambient noise levels in the project vicinity and the impact would be **less than significant.**

Operational Vibration

The Proposed Project is not anticipated to produce significant levels of groundborne vibration once operational. While the project would include rotating machinery (i.e., pumps and motors), it is anticipated that this equipment would be well-maintained and balanced as part of the general long-term maintenance of the facility, which would prevent excessive vibration. In addition, it is assumed that the equipment would be installed according to the manufacturers' requirements, including any recommended resilient mounts. Furthermore, the largest of the equipment items would be installed below ground and the mass of the structure (a concrete vault/building) would be large relative to the mass of the rotating machinery, which would limit the ability of such machinery to induce significant levels of vibration in the structure of the VAPP. Therefore, **no impact** is anticipated.

3.9.5 Mitigation Measures

The following mitigation measures were developed to avoid or minimize the Proposed Project's potential impacts related to noise and vibration.

MM-NOI-1: Prepare and Implement a Construction Noise Control Plan to Reduce Construction Noise at Noise-Sensitive Land Uses. To reduce the significant construction noise impacts, the Los Angeles Bureau of Engineering (LABOE) and Contractor shall develop a noise control plan that includes the implementation of the following noise reduction measures during construction:

a) Construction activities shall occur only between 8:00 a.m. to 6:00 p.m. Monday through Saturdays. No construction activity shall occur on national holidays or at any time on Sundays. The use of the pile driver, grader and jackhammer construction equipment shall be limited to the hours of 9 a.m. to 3:30 p.m. Haul trucks can only access the site through local neighborhood streets from 9 a.m. to 4 p.m. Construction personnel shall not be permitted on the Project Site (including laydown and storage areas), and material or equipment deliveries and collections shall not occur outside of these hours. In addition, no construction worker parking would be allowed along Hurricane Street or on adjacent streets. Construction workers shall park offsite and arrive by shuttle to the construction site, as arranged by the construction contractor.

b) All piles, including sheeting, shall be installed and extracted using vibration- and percussive-free methods.

c) Noise coordinator - LABOE and/or its Contractor shall maintain good communication with the surrounding community regarding the schedule, duration, and progress of the construction. Residents at properties within 500 feet of construction activities shall be notified 72 hours in advance of the planned activities prior to the start of work. The notification shall advise that there will be loud noise associated with the construction, and shall state the date, time, and expected duration of the planned activities. The notification shall provide a telephone contact number for affected parties to ask questions or share any concerns. A noise coordinator for the project will be required to maintain a call log, so that the City can track resolution and nature of any noise complaints. This call log containing the name and address (if available) of the complainant, including time and reason for call shall be provided to the Public Works Department (Public Affairs Office, LA Sanitation, LABOE) upon request. Further, residents shall be informed of the noise coordinator and on-site

construction supervisor contact information by posting of the phone number on the construction site.

d) To the extent practicable, temporary noise barriers with a minimum height of 20 feet shall be employed around the Project Site. Openings in the barriers shall be kept to the minimum necessary for access of vehicles, equipment, and construction material. These barriers shall be constructed as follows.

   - From commercially available acoustical panels lined with sound-absorbing material (the sound-absorptive faces of the panels shall face the construction equipment); or,
   - From acoustical blankets hung over or from a supporting frame. The blankets shall provide a minimum sound transmission class rating of 28 and a minimum noise-reduction coefficient of 0.80 and shall be firmly secured to the framework with the sound-absorptive side of the blankets oriented toward the construction equipment. The blankets shall be overlapped by at least 6 inches at seams and taped so that no gaps exist. The largest blankets available shall be used in order to minimize the number of seams. The blankets shall be draped to the ground to eliminate any gaps at the base of the barrier.

e) For noise-generating equipment that cannot be shielded by site perimeter barriers, localized noise barriers or enclosures shall be employed wherever feasible. The height and location of these barriers/enclosures shall be designed to block the line of sight between the equipment and the surrounding homes.

f) LABOE/Contractor shall retain the services of an acoustical/noise consultant to prepare a Noise Monitoring Plan.

   - This shall be a site-specific plan for monitoring and reporting construction noise levels in the community to evaluate the Contractor's performance.
   - Based on the details of the Contractor's specific construction schedule, the plan shall develop construction noise goals, in terms of the 1-hour Leq, that should be achieved for each phase of construction with the inclusion of feasible and practicable noise abatement measures.
   - If noise monitoring indicates the applicable noise goals have been exceeded, steps shall be taken to promptly implement any additional effective abatement measures that are feasible and/or practicable.

g) To the fullest extent practicable, the quietest available type of construction equipment shall be used. Newer equipment is generally quieter than older equipment. The use of electric-powered equipment is typically quieter than diesel- or gasoline-powered equipment, and hydraulic-powered equipment is typically quieter than pneumatic-powered equipment.

h) All construction equipment used on the Proposed Project that is regulated for noise output by a local, state, or federal agency shall comply with such regulation while in the course of project activity and use on site.

i) All construction equipment shall be properly maintained. (Poor maintenance of equipment may cause excessive noise levels.)

j) All construction equipment shall be equipped with properly operating and maintained mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features that meet or exceed original factory specifications.

k) All construction equipment shall be operated only when necessary, and shall be switched off when not in use. Idling inactive construction equipment for prolonged periods (i.e., more than 2 minutes) shall not be permitted.

l) The use of noise-producing signals, including horns, whistles, alarms, and bells, shall be for safety warning purposes only.

m) No project-related public address or music system shall be audible at any adjacent residential receptor.

n) Construction employees shall be trained in the proper operation and use of the equipment. (Careless or improper operation or inappropriate use of equipment can increase noise levels. Poor loading, unloading, excavation, and hauling techniques are examples of how a lack of adequate guidance and training may lead to increased noise levels.)

o) Stationary noise sources such as generators and compressors shall be positioned as far as possible from noise sensitive areas.

p) Construction equipment shall be stored on the Project Site or designated laydown areas while in use, to the extent feasible. This will eliminate noise associated with repeated transportation of the equipment to and from the site.

q) To the extent possible, haul roads shall not be designated through noise-sensitive areas.

MM-NOI-2: Implement ground-borne vibration control measures to reduce construction-generated vibration. To reduce the significant construction vibration impacts, LABOE/Contractor shall implement the following vibration reduction measures during project construction:

a) All piles, including sheeting, shall be installed and extracted using vibration- and percussive-free methods.

b) LABOE and/or Contractor shall retain a qualified structural or geotechnical engineer to conduct pre-construction surveys of adjacent neighboring structures (including photographing and/or videotaping) to document existing building conditions for future comparison if any vibration-related damage is suspected or results from construction-related activities.

c) If considered appropriate by the structural/geotechnical engineer, monitoring shall be conducted during construction to check for vibration-related damage from equipment during its use. Such monitoring may include vibration measurements obtained inside or outside of the buildings, or other tests and observations deemed necessary.

MM-NOI-3: Design project facilities to reduce noise from all mechanical and electrical equipment to levels that comply with applicable regulations. To reduce the significant operational noise impacts to less than significant, noise control features shall be included during the final architectural and engineering design phase of the project, to reduce overall operational noise levels from all project-related sources to within 5 dB CNEL of existing ambient noise levels in the surrounding community (53 to 57 dB CNEL, as described in Table 3.9-6), and to comply with Chapter XI of the City of Los Angeles Municipal Code (i.e., restrict noise level increases, relative to

the existing 1-hour L_{eq}, to 5 dBA or less). The City shall retain an acoustical/noise consultant to evaluate the design and provide recommendations for specific noise-control features, as necessary, feasible, and practicable, based on the final equipment selections and specifications for the project. Such noise control features may include, but are not limited to, the following.

a) Selecting equipment with lower sound power levels.

b) Adjusting the location of equipment items within the Project Site to increase the distance from the closest sensitive receptors and/or increase acoustical shielding provided by intervening structures, where practicable and feasible.

c) Shielding noise-generating equipment with screens, acoustical panels, enclosures, or block walls.

d) Using sound-rated doors, windows, and access hatches at the electrical building and subterranean vault.

e) Adding sound-absorptive materials to interior spaces to reduce buildup of reverberant noise levels.

f) Designing ventilation systems with acoustical louvers, intake and exhaust silencers, and other features to control exterior noise propagation from interior sources.

3.9.6 Significant Unavoidable Adverse Impacts

While MM NOI-1 would reduce construction noise levels to the extent feasible, it would not eliminate the predicted noise impacts entirely; therefore, construction noise impacts are considered significant and unavoidable.

While MM NOI-2 would substantially reduce construction vibration levels and mitigate the potential impacts related to building damage, it would not eliminate all the predicted impacts related to annoyance at nearby residences; therefore, construction vibration impacts are considered significant and unavoidable.

It is noted that all significant and unavoidable impacts related to project construction would be temporary and would cease once project construction is complete.

All operational noise impacts would be less than significant after implementation of MM NOI-3.

3.9.7 Cumulative Impacts

As identified in Chapter 1, Introduction, a number of related projects are proposed in relatively close proximity to the Project Site (within 0 to 0.5 miles). The following sections discuss the cumulative impacts that could occur if construction or operation of these related projects occurs simultaneously with the Proposed Project.

3.9.7.1 Construction

Noise

Some of the related projects would bring additional construction activity into the immediate vicinity of the Project Site. Specifically, the Venice Dual Force Main Project and projects at the existing VPP would require the use of heavy construction equipment that would affect the same nearby receptors

affected by the Proposed Project. Assuming similar construction equipment could be used for two projects simultaneously, the total amount of construction equipment could be doubled, leading to a 3 dB increase in construction noise levels at adjacent receptors. While the Venice Dual Force Main Project construction activity is expected to be completed in the vicinity of the VPP before the start of construction of the proposed VAPP project, it is possible that some portions of the projects in Marina del Rey could still be occurring and overlap with the VAPP construction period. Because project construction noise impacts are predicted to be significant, the cumulative impact would also be significant. While **MM NOI-1** would reduce the Proposed Project's contribution to cumulative noise levels to the extent feasible, it would not eliminate the predicted noise impacts entirely; **therefore, cumulative construction noise impacts are considered significant and unavoidable**.

Vibration

Vibration from construction activities is assessed based on distinct single events using the instantaneous vibration (PPV) from a single piece of equipment. Therefore, the vibration levels experienced at any specific time at a given receptor are typically dominated by a single piece of construction equipment, and the cumulative increase due to additional pieces of equipment is minimal. However, because project construction vibration impacts are predicted to be significant, the cumulative impact would also be significant. While MM NOI-2 would substantially reduce the Proposed Project's contribution to construction vibration levels and mitigate the project's potential impacts related to building damage, it would not eliminate all the predicted impacts related to annoyance at nearby residences; therefore, cumulative construction vibration impacts are considered **significant and unavoidable**.

3.9.7.2 Operation

Noise

Once operational, noise and vibration levels from related projects are expected to be less than significant either because of the nature of the projects themselves (for instance, subterranean pipelines would not be expected to generate significant noise in the surrounding community) and/or because each project would be required to comply with the City Municipal Code's noise limits. Because **MM NOI-3** would reduce the Proposed Project's operational noise levels to comply with both the municipal code and the thresholds of the City's CEQA Guidelines, the cumulative operational noise impacts would also be **less than significant**.

Vibration

As discussed above, the Proposed Project is not anticipated to produce significant levels of groundborne vibration once operational and would, therefore, not have a meaningful contribution to cumulative operational vibration levels (if any) in the area. Furthermore, one of the related projects is actually proposed for the purposes of reducing vibration levels at the adjacent VPP which would lead to an improvement over existing conditions related to that facility. Consequently, the cumulative operational vibration impacts are anticipated to be **less than significant**.

3.10 Transportation/Traffic

This section describes the regulatory setting, existing transportation/traffic conditions at the Project Site and associated study area (see below) and the potential impacts that would result from implementation of the Proposed Project. It also identifies, where necessary, mitigation measures to reduce identified significant impacts. As noted in the analysis below, with the implementation of mitigation measures, direct and indirect impacts associated with transportation/traffic conditions during construction and operation of the Proposed Project would be less than significant.

3.10.1 Regulatory Setting

A review of the various regulatory requirements was conducted to identify regulations that address traffic and transportation. This section summarizes the various regulatory requirements that are relevant to the Proposed Project.

3.10.1.1 Federal

There are no federal regulations or policies regarding transportation and traffic that are applicable to the Proposed Project.

3.10.1.2 State

There are no state regulations or policies regarding transportation and traffic that are applicable to the Proposed Project.

3.10.1.3 Local and Regional

Southern California Area Governments Regional Transportation Plan/Sustainable Communities Strategy

The Southern California Association of Governments (SCAG) is a Joint Powers Authority under California state law and was established as an association of local governments and agencies that voluntarily convene as a forum to address regional issues. The SCAG region encompasses six counties (Imperial, Los Angeles, Orange, Riverside, San Bernardino and Ventura), 191 cities in an area covering more than 38,000 square miles and six County Transportation Commissions that hold the primary responsibility for programming and implementing transportation projects, programs and services in their respective counties.

SCAG is designated under federal law as a Metropolitan Planning Organization (MPO) and as a Regional Transportation Planning Agency and a Council of Governments under state law. SCAG Bylaws provide for representation of Air Districts in the region. SCAG develops long-range regional transportation plans including growth forecast components, regional transportation improvement programs and a portion of the South Coast Air Quality management plans.

According to SCAG, their Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS) is a long-range visioning plan that balances future mobility and transportation needs with economic, environmental and public health goals. The RTP/SCS consists of a vision for the region's future and is developed with input from local governments, county transportation

commissions (CTCs), tribal governments, non-profit organizations, businesses and local stakeholders within their region.

There are over 4,000 transportation projects from local county plans —ranging from highway improvements, railroad grade separations, bicycle lanes, new transit hubs and replacement bridges that are included in the 2016 RTP/SCS. These future investments seek to reduce traffic bottlenecks, improve the efficiency of the region's network and expand mobility choices for everyone.

County of Los Angeles Congestion Management Program

The Los Angeles Congestion Management Program (CMP) is a state-mandated program enacted by the California State Legislature with the passage of Proposition 111 in 1990, administered by the Los Angeles County Metropolitan Transportation Authority (Metro). The purpose of the CMP is to develop a coordinated approach to managing and decreasing traffic congestion by linking the various transportation, land use, and air quality planning programs throughout the County. One required element of the CMP is a process to evaluate the transportation and traffic impacts of large projects on the regional transportation system. That process is undertaken by local agencies, project applicants, and traffic consultants through a transportation impact report usually conducted as part of the CEQA project review process.

The 2010 CMP for the County (adopted October 28, 2010) was developed in part to link local land use decisions with their impacts on regional transportation. The CMP identifies a system of highways and roadways, with minimum levels of service (LOS)[1] performance measurements designated at LOS E (unless exceeded in base year conditions) for highway segments and key roadway intersections on this system. A traffic impact analysis (TIA) is required for projects that generate at least 50 new trips at CMP intersections during the peak hour or 150 trips to mainline freeway locations. The analysis must: investigate measures that will mitigate the significant CMP system impacts; develop cost estimates, including the fair share costs to mitigate impacts of the Proposed Project; and, indicate the responsible agency. Selection of final mitigation measures is left at the discretion of the local jurisdiction. Once a mitigation program is selected, the jurisdiction self-monitors implementation through the existing mitigation monitoring requirements of CEQA.

City of Los Angeles Mobility Plan 2035

In August 2015, the City of Los Angeles (City) updated the Transportation Element of the City's General Plan, now referred to as Mobility Plan 2035, or MP 2035, to reflect policies and programs that will lay the policy foundation for safe, accessible, and enjoyable streets for pedestrians, bicyclists, transit users, and vehicles throughout the city of Los Angeles. The MP 2035 and Final EIR were adopted on August 11, 2015 and are compliant with the 2008 Complete Streets Act, which mandates that the circulation element of a city's General Plan be modified to plan for a balanced, multimodal transportation network that meets the needs of all users of streets, roads, and highways, defined to include motorists, pedestrians, bicyclists, children, person with disabilities, seniors, movers of commercial goods, and users of public transportation, in a manner that is suitable to the rural, suburban, or urban context of the general plan.

[1] LOS is a qualitative measure that is used to describe the condition of traffic flow, ranging from excellent conditions (LOS A) to overloaded conditions (LOS F). The City of Los Angeles uses LOS D as a standard, meaning LOS D or better is considered satisfactory conditions, while LOS E or F is generally considered to be substandard.

City of Los Angeles 1999 General Plan Transportation Element

At the time of this Draft EIR, the Mobility Plan 2035 is subject to legal challenge. In the event the litigation results in the Mobility Plan 2035 being stayed or overturned, the 1999 Transportation Element will be the effective circulation element for the City's General Plan. Therefore, in an excess of caution, the City has included a brief discussion of the Transportation Element.

The Transportation Element includes a discussion of the existing roadway infrastructure in the city of Los Angeles. Goals, objectives, and policies are included in the transportation element to ensure efficient circulation within the city and region.

Coastal Transportation Corridor Specific Plan

The Coastal Transportation Corridor Specific Plan Area consists of all or parts of the Westchester-Playa Del Rey Community Plan Area, the Palms-Mar Vista-Del Rey Community Plan Area, the Venice Community Plan Area, and the Los Angeles International Airport Interim Plan Area, generally bounded by the city of Santa Monica on the north, Imperial Highway on the south, San Diego Freeway on the east, and the Pacific Ocean on the west and has the following purposes:

- Provide a mechanism to fund specific transportation improvements due to transportation impacts generated by the projected new commercial and industrial development within the corridor;
- Establish the Coastal Transportation Corridor Impact Assessment Fee process for new development in the C, M, and P Zones and for development on property owned by the Department of Airports;
- Regulate the phased development of land uses, insofar as the transportation infrastructure can accommodate such uses;
- Establish a Coastal Transportation Corridor infrastructure implementation process;
- Promote or increase work-related ridesharing and bicycling to reduce peak-hour trips and to keep critical intersections from severe overload;
- Avoid peak-hour LOS on streets and interchanges from reaching LOS F or, if presently at LOS F, preclude further deterioration in the LOS;
- Promote the development of coordinated and comprehensive transportation plans and programs with other jurisdictions and public agencies;
- Reduce commute trips by encouraging the development of affordable housing at or near job sites;
- Ensure that the public transportation facilities that will be constructed with funds generated by the Specific Plan will significantly benefit the contributor; and
- Encourage Caltrans to widen the San Diego Freeway for high-occupancy vehicle lanes.

Venice Local Coastal Program

The Venice Local Coastal program (LCP) was prepared to comply with the California Coastal Act of 1976. The Coastal Act directs each local government lying wholly or partly within the Coastal Zone to prepare an LCP for those areas located in the state's designated Coastal Zone. The Venice Coastal Zone is the area generally bounded by Marine Street on the north, the city-county boundary, Washington Boulevard and Via Marina on the south, Lincoln Boulevard and Via Dolce on the east, and the Pacific Ocean on the west.

Venice Specific Plan

The purpose of the Venice Specific Plan is to implement the policies and goals of the California Coastal Act and regulate all development, including parking in order that it be compatible in character with the existing community. Section 13 of the Venice Specific Plan specifically addresses parking standards and requirements as well as Beach Impact Zone parking requirements for new development within the Venice Coastal Zone.

Venice Local Coastal Program Land Use Plan

The purpose of the Venice LCP-LUP is to define goals and land use policies for compliance with the California Coastal Act. It is intended to restore the overall quality of the Venice Coastal Zone environment and its natural and man-made resources and assures that public coastal access and public recreation areas are provided as required per the Coastal Act.

The following CA Coastal Act policies are included as part of the Venice LCP LUP:

Article 2. Public Access

> 30212. "(a) Public access from the nearest public roadway to the shoreline and along the coast shall be provided in new development projects except where (1) it is inconsistent with public safety, military security needs, or the protection of fragile coastal resources, (2) adequate access exists nearby, or (3) agriculture would be adversely affected. Dedicated accessway shall not be required to be opened to public use until a public agency or private association agrees to accept responsibility for maintenance and liability of the accessway."

Article 6. Development

> 30252. "The location and amount of new development should maintain and enhance public access to the coast by…..providing non-automobile circulation within the development and provide adequate parking facilities or providing substitute means of serving the development with public transportation."

Venice LCP LUP Policy Group II, *Shoreline Access Policy II. A. 3. Parking Requirements*, outlines parking requirements that shall apply to all new development. Extensive remodeling of an existing use or change of use that does not conform to the parking requirements shall be required to provide missing numbers of parking spaces or provide an in-lieu fee payment into the Venice Coastal Parking Impact Trust Fund for the existing deficiency. Public Utility Facility not having a Business Office on the premises requires 2 spaces; plus 1 space for each 500 square feet of floor area. Parking shall be provided pursuant to a detailed parking study that demonstrates that the project will provide adequate parking to meet the needs of the development without causing negative impacts to coastal access or access to public recreational facilities. (City of Los Angeles 2001).

Policy Group II Shoreline Access as it pertains to parking is considered a Venice Coastal Issue consistent with the California Coastal Act and has been identified in the Venice LCP LUP as the following:

The following parking issues have been identified as part of the Venice LCP LUP:

- Conflict between residential and beach visitor parking.
- Inadequate signage of available parking for beach visitors on weekends resulting in added traffic congestion.
- Inadequate parking provided by non-conforming uses.

- Inadequate off-street parking near or on the beach frontage for visitors and residents.
- Intrusion of non-resident vehicles on residential streets to locate available parking spaces.
- Preventing polluted stormwater runoff from parking lots from entering the Venice Canals and Ballona Lagoon.

3.10.2 Environmental Setting

This section describes the environmental setting or conditions related to traffic and transportation in the project vicinity, which represents the baseline required to evaluate the Proposed Project's impacts and identify required mitigation measures.

3.10.2.1 Existing Street System

Primary regional access to the Project Site is provided by the Marina Freeway (SR 90), the San Diego Freeway (I-405), and the Santa Monica Freeway (I-10). SR 90 runs east of the Project Site along a diagonal east of Marina Del Rey. Access to the Project Site from SR 90 can be obtained from Lincoln Boulevard (SR 1). I-10 runs in an east/west direction north of the study area and I-105 runs east/west south of the study area. Both I-10 and I-105 connect with I-405 to the north and south, respectively. Washington Boulevard, located approximately 0.3 mile north of the Project Site, serves as the nearest and primary commercial corridor. The Project Site is located at the northeast corner of Hurricane Street and Canal Court, across from and immediately north of the existing VPP. Figure 2-2, Project Location Map (see Chapter 2, Project Description of this EIR) shows the project location along with local existing pedestrian and vehicular access.

The main streets carrying project-related construction traffic (both worker trips and truck trips) to the construction site would be: Lincoln Boulevard, Washington Boulevard, Venice Boulevard (SR 187), Pacific Avenue, Hurricane Street, Canal Court, and Galleon Street. These boulevards, avenues, and local streets in the project's study area offer sub-regional and local access and circulation opportunities. These facilities generally provide two to four travel lanes and allow parking on one side of the street. However, both Hurricane Street and Canal Court are narrow roadways that do not allow two vehicles to pass at the same time. This condition creates the need for drivers to wait to pass one another.

Below is a brief description of the major streets serving the Proposed Project Site. Sidewalks are generally available in the vicinity of the project area, except along Canal Court.

- Canal Court – Canal Court is a short undivided alleyway that runs between Driftwood Street to the north and the Ballona Lagoon to the south. Parking is not permitted along Canal Court.
- Galleon Street – Galleon Street is a short undivided local street that runs east/west between Pacific Avenue and Esplanade, just west of the Venice Canal/Ballona Lagoon. Parking is permitted on both sides of the street, though some restrictions are present along several properties.
- Hurricane Street – Hurricane Street is a short undivided local street that runs east/west between Ocean Front Walk and Esplanade, just west of the Venice Canal/Ballona Lagoon. The street terminates adjacent to the Project Site and parking is permitted on both sides of the street.

- Lincoln Boulevard (SR 1) – SR 1 is an arterial street that runs north/south in the study area and it generally provides four travel lanes. Metered parking is available on both sides of the street and the speed limit is 35 miles per hour (MPH).
- Marquesas Way – Marquesas Way is a short four-lane secondary street that runs east/west and connects Via Dolce and Via Marina. Parking is permitted on the east side of the street and the speed limit is 25 MPH.
- Pacific Avenue – Pacific Avenue is a two-lane secondary arterial that runs north/south between Barnard Way to the north and Via Marina to the south. Between Washington Boulevard and Hurricane Street, parking is restricted along the east side of the street but it is unrestricted on the north side. The posted speed limit within this segment is 30 MPH.
- Via Marina – Via Marina is a four-lane street that runs north/south between Washington Boulevard and Pacific Avenue. No parking is allowed on either side of the street and the speed limit is 40 MPH.
- Via Dolce – Via Dolce is a secondary arterial that runs north/south between Washington Boulevard and Marquesas Way. It includes two northbound lanes and one southbound lane, plus bicycle lanes. Parking is allowed on both sides of the street and the speed limit is 35 MPH.
- Washington Boulevard – Washington Boulevard is a Major Highway Class II arterial street that runs east/west between Venice Beach and the City of Whittier. It generally provides four travel lanes plus bicycle lanes. Metered parking is generally available on both sides of the street. The speed limit is 35 MPH.

3.10.2.2 Existing Traffic Congestion and Levels of Service

As part of the Venice Dual Force Main (VDFM) Draft EIR prepared in 2006, the City conducted a detailed assessment of the existing operating conditions at 23 roadway segments and nine intersections in the vicinity of the Project Site's directly adjacent Venice Pumping Plant. In response to comments received on the Draft EIR and minor changes in the project description, the traffic study was updated in June 2009. The data collected and projected as part of that study is adequate to reflect existing conditions today since the area has not experienced significant change or new development that would have significantly added or reduced traffic patterns in the vicinity of the project area.

Of the roadway segments studied that are now within the project vicinity, the roadway segments were projected to operate at LOS D or better during morning and afternoon peak hours in the future (2011). Of the intersections studied that are now within the current project study area, three intersections would also serve the Project Site. The VDFM Traffic Study projected the intersection volume to capacity (V/C) ratio and corresponding LOS, as shown in Table 3.10-1 below.

As shown in Table 3.10-1, four of the six study intersections were projected to operate at LOS D or better during all analyzed peak hours. The intersection of Via Marina & Washington Boulevard was projected to operate at LOS E in the PM peak hour and LOS F in the Sunday midday peak hour. The intersection of Lincoln Boulevard & Washington Boulevard was projected to operate at LOS F during all three peak hours.

Table 3.10-1. Year 2011 Intersection Level of Service

Intersection	Peak Hour	VC or Delay	LOS
Pacific Avenue & Washington Boulevard	AM	0.657	B
	PM	0.797	C
	Weekend	0.512	A
Via Marina & Washington Boulevard	AM	0.863	D
	PM	0.934	E
	Weekend	1.029	F
Lincoln Boulevard & Washington Boulevard	AM	1.088	F
	PM	1.120	F
	Weekend	1.190	F
Via Marina & Marquesas Way	AM	0.325	A
	PM	0.253	A
	Weekend	0.331	A
Via Marina & Tahiti Way	AM	0.321	A
	PM	0.208	A
	Weekend	0.287	A
Via Marina & Bora Bora Way	AM	2.8	A
	PM	2.5	A
	Weekend	2.0	A
worst approach only	AM	11.7	B
worst approach only	PM	11.1	B
worst approach only	Weekend	12.0	B
If signalized	AM	0.438	A
If signalized	PM	0.372	A
If signalized	Weekend	0.450	A

Notes:
AM Peak Hours = 7:00 am – 9:00 am
PM Peak Hours = 4:00 pm – 6:00 pm
2011 Intersection LOS is based on the Year 2011 cumulative base (without project) conditions contained in the VDFM Traffic Study prepared by Fehr & Peers, 2009.
Source: Fehr & Peers, 2009.

3.10.2.3 Existing CMP Facilities

The CMP arterial monitoring intersection nearest to the Project Site is located at Lincoln Boulevard (SR 1) and SR 90 (Marina Expressway), which is approximately 1.2 miles to the northeast. Additionally, two additional arterial monitoring locations are located at the intersection of Lincoln Boulevard and Venice Boulevard (SR 187) approximately 1.3 miles to the northwest of the Project Site. West of this intersection, SR 187 is considered Other Principal Arterial. No other immediate streets surrounding the Project Site and vicinity are considered CMP facilities. The 2010 CMP showed these intersections to be operating at LOS D or better during both AM and PM peak hour.

3.10.2.4 Existing Parking

Parking within the community is predominantly unrestricted, publicly available, and on street. A City-owned off-street parking lot is located on the northwestern edge of the study area, at the terminus of Washington Boulevard, which includes a total of 364 parking spaces (329 regular, 26 extended spaces for recreational vehicles, and 9 spaces designated for disabled parking). Hurricane Street, where the Project Site is located, also contains restricted (street sweeping) on-street parking. The local street sweeping schedule varies by street but parking is generally restricted on Mondays or Tuesdays from 10:00 AM to 12:00 PM. Parking is prohibited on Canal Court.

3.10.2.5 Existing Transit System

Transit service within the study area is provided as follows:

- Metro Lines 108 and 358 operate on Pacific Avenue between Via Marina and Washington Boulevard and along Washington Boulevard between Pacific Avenue and Palawan Way. The lines run between Marina del Rey and Pico Rivera, with Line 358 providing limited stop service during the peak periods.
- Culver City Blue Bus Line 1 provides service on Washington Boulevard between Venice and the West Los Angeles Transit Center.
- Commuter Express Line 437 is operated by LAODT and runs on Via Dolce and Pacific Avenue in the project area. This line runs between Marina del Rey and downtown Los Angeles.

3.10.2.6 Non-Motorized Transportation

Biking and walking are non-motorized transportation modes that typically serve shorter trips than do motorized travel modes. In the project area, bikeways facilitate and encourage this mode of non-motorized transportation. According to LADOT, Class I bikeways are separate off-street paths, Class II bikeways are striped lanes within streets, and Class III bikeways are signed bicycle routes. The nearest dedicated bicycle lane is located along Washington Boulevard north of the Project Site and Via Dolce east of the Project Site. Pedestrian access at and near public transit, in local commercial and residential areas is facilitated by sidewalks, which are present on most streets, except Canal Court. Esplanade provides walking paths along the Grand Canal and Ballona Lagoon areas.

3.10.3 Environmental Impact Analysis

3.10.3.1 Methodology and Assumptions

This section describes the procedures used to assess impacts on the traffic and transportation system. Assumptions regarding the types of transport and the types of roads used to haul materials and workers were used to estimate the number of trips to be generated by the Proposed Project and assess the overall significance of project impacts. For purposes of assessing the project's traffic impact upon adjacent roadways, the project's net additional construction and operation traffic trip generation was qualitatively compared against existing traffic conditions. In determining the level of significance, the assessment assumed that the implementation of the Proposed Project would comply with relevant regulations, ordinances, and guidance.

The traffic projections for the Proposed Project were developed using three steps: estimating the trip generation of the project, determining trip distribution, and assigning the project traffic to the

roadway system. The information used in this analysis was provided by the Los Angeles Bureau of Engineering (LABOE) and the project team. Construction of the project is planned to begin in March 2018 and is expected to take approximately 24 months to complete, ending in 2020. The construction involves several key phases, which may overlap, as described below.

1. Stages 1-2: Mobilization, Site Preparation, and Excavation – three to four months (155 days), including approximately two to three months of soil hauling;
2. Stage 3: Pump Station Foundation/Electrical – nine to 10 months;
3. Stage 4: Diversion Structure – four to six months; and
4. Stages 5-6: Pump Station Integration/Finishing – two to four months.

The Los Angeles Municipal Code (LAMC) provides that construction activities are limited to the hours from 7:00 a.m. to 9:00 p.m. on weekdays and from 8:00 a.m. to 6:00 p.m. on Saturdays and holidays. No construction is permitted on Sundays. VAPP construction hours are proposed to be Monday through Saturday from 8:00 a.m. to 6:00 p.m. (See MM NOI-1). While other construction-related traffic could occur anytime within the allowable hours, soil hauling truck hours would occur between 9:00 a.m. and 4:00 p.m. Monday through Saturday. It is planned that construction workers would park at an off-site location and be shuttled to and from the Project Site each workday by passenger shuttles or vans (that have the capacity to seat 10 to15 passengers). While no specific off-site location has been identified at this time, it would likely lie within five miles of the Project Site. The selected contractor would be required to identify and secure a suitable location. In general, work is planned to occur between 8:00 a.m. and 6:00 p.m., and worker shuttles are expected to depart the site by 6:00 p.m. On days when soil export is occurring, workers would all be onsite before soil trucks begin to arrive and would remain on-site until after the last soil export truck departs. Appendix J (Trip Generation Analysis, October 3, 2016) of this EIR presents the estimated vehicle trip generation at the Project Site during the analyzed peak hours and on a typical weekday.

In addition to soil haul trucks, the project would generate equipment and delivery truck trips during each phase of construction. Such trips are estimated to be two per day (four passenger car equivalents [PCE] trips per day) and could include cranes, bulldozers, excavators, and other large items of machinery. These materials would be delivered to the site and stored on-site at one of two laydown areas (see Chapter 2, Project Description).

The number of construction workers would vary throughout the construction period. During Stages 1 and 2 and Stage 4, approximately eight workers would be on-site each day. Stage 3 would require up to 20 workers on-site daily. Stages 5 and 6 would require approximately six workers per day. Table 3.10-2 summarizes the daily trip generation by construction stage.

Table 3.10-2. Daily Trip Generation by Construction Phase

Stage	Stage Name	Duration (days)	Daily Workers by Phase	Worker Trips at Site per day*	Soil Haul Truck Trips per Day**	Other Truck Trips per Day	Total Daily 1-way Vehicle Trips	Total Daily 1-way PCE Trips
1-2	Mobilization/	30	3	4		2	6	8
	Site Preparation/ Excavation/ Shoring	95	8	4	48	2	54	104
3	Pump Station Foundation	50	20	8	48	2	10	12
	Pump Station	245	20	8		2	58	108
4	Diversion Structure	64	8	4	0	2	6	8
5-6	Pump Station Integration	85	6	4	0	2	6	8

Notes:
PCE – passenger car equivalency
*Assumes that employees will be shuttled to/from the Project Site after parking off-site. Capacity of shuttle is assumed to be 15 passengers or less.
** 10,000 cubic yards of soil will be excavated and exported during Stages 1 and 2, of which approximately 2,300 cubic yards would be stockpiled at Laydown Area 1 and approximately 7,700 cubic yards of soil would be stockpiled at Laydown Area 3. If needed, up to 3,850 cubic yards will be imported (returned) back to the VAPP site use as backfill during Stage 3 and 4. The balance of the exported soil is expected to be used as cover at an area landfill, such as Sunshine Canyon.

3.10.3.2 Screening Analysis

The *L.A. CEQA Thresholds Guide* (2006) includes two sets of criteria to evaluate project impacts: screening and significance criteria. The screening criteria assist in deciding when further study is needed to determine whether a project impact could be significant. For many issue areas, further study is recommended when one or more questions are answered with a "yes." A "no" response to all questions indicates that further study is not required, and there would normally be no significant impact from the Proposed Project on the subject issue.

The *L.A. CEQA Thresholds Guide* (2006) includes the screening criteria outlined below for Transportation and Traffic (L.1 through L.8) to determine if additional study is necessary. Table 3.10-3 below summarizes whether the project impacts would require further study based on the screening criteria.

Table 3.10-3. Summary of Screening Analysis

Screening Criteria	Requires Further Study? Yes/No
L.1. Intersection Capacity, L.2. Street Segment Capacity	
Would the Proposed Project generate and/or cause a diversion or shift of 500 or more daily trips or 43 or more PM peak-hour vehicle trips on the street system?	No
L.3. Freeway Capacity	
Would the Proposed Project add 150 or more one-way vehicle trips to a Congestion Management Program (CMP) mainline freeway monitoring segment during either the AM or PM peak hours?	No
Would the Proposed Project add 50 or more AM or PM peak-hour trips to a freeway on- or off-ramp?	No
L.4. Neighborhood Intrusion Impacts	
Would the Proposed Project generate more than 120 daily vehicle trips to a local residential street?	No
L.5. Project Access	
Would the Proposed Project generate and/or cause a diversion or shift of 500 or more daily trips or 43 or more PM peak-hour vehicle trips on the street system?	No
Is a project driveway proposed on a major or secondary highway within 150 feet of an intersection with another major or secondary highway?	No
Would a project driveway intersect an on-street bicycle lane or cross a sidewalk in an area of high pedestrian activity?	No
Can it be readily perceived that there are access risks or deficiencies associated with the adjoining street system due to curves, slopes, walls, or other barriers to adequate lines of sight?	No
L.6. Transit System Capacity	
Will an Environmental Impact Report (EIR) be prepared for the Proposed Project to evaluate potential transportation impacts??	
L.7. Parking	
Would the project's proposed parking supply be less than that required by City code, including Los Angeles Municipal Code (LAMC), Transportation Specific Plan (TSP) or Interim Control Ordinance (ICO) requirements, prior to applying for a variance, exemption, or amendment, if any apply to the project?	No
If the project is located within the coastal zone (generally, 1,000 yards inland of the mean high tide line), would the project's proposed parking supply be less than that required by California Coastal Commission requirements?	No
L.8. In-Street Construction Impacts	
Would a project not exempted in Article VII of the City CEQA Guidelines require construction activities to take place within a major or secondary highway ROW that would necessitate temporary lane, alley, or street closures for more than one day (including day and evening hours, and including overnight closures if on a residential street)?	No
Would a non-exempt project require construction activities to take place within a collector or local street ROW that would necessitate temporary lane, alley, or street closures for more than seven days (including day and evening hours, and including overnight closures if on a residential street)?	Yes

Screening Criteria	Requires Further Study? Yes/No
Would in-street construction activities result in the loss of regular vehicular or pedestrian access to an existing land use for more than one day, including day and evening hours and overnight closures if access is lost to residential units?	No
Would in-street construction activities result in the temporary loss for more than one day of an existing bus stop or rerouting of a bus route that serves the Project Site?	No
Source: *L.A. CEQA Thresholds Guide*, 2006; Fehr & Peers, 2016.	

L.1. Intersection Capacity, L.2. Street Segment Capacity

- **Would the Proposed Project generate and/or cause a diversion or shift of 500 or more daily trips or 43 or more PM peak-hour[2] vehicle trips on the street system?**

  According to the *L.A. CEQA Thresholds Guide* (2006), a "no" response to the preceding question indicates that there would normally be no significant Intersection Capacity and Street Segment Capacity impacts from the Proposed Project. Trip generation estimates that were prepared for the project were based upon projected staffing and truck activity levels. Trip generation estimates represent a worst-case scenario in that they consider the upper bounds of impacts likely to be experienced on the street system in the immediate vicinity of the Project Site where construction activities could result in temporary lane closures and loss of on-street parking.

  The number of vehicle trips generated by the project are expected to be up to a total of 58 daily one-way vehicle trips as the worst-case scenario (up to 48 soil haul, 8 construction worker, and 2 other trips). Considering the passenger car equivalency (PCE) factor of 2.0 for the truck trips, this stage of construction would result in up to 108 daily PCE trips.

  However, the number of construction workers and construction equipment would actually vary throughout the construction day in order to maintain a reasonable schedule of completion. Construction workers are anticipated to be onsite before 8:00 a.m. and would typically leave the Project Site before 6:00 p.m. While they would be commuting during morning and afternoon peak hours, the number of these trips would be negligible. As soil haul trucks will be restricted to the hours of 9:00 a.m. to 4:00 p.m. (see MM NOI-1), they will avoid morning peak (7:00 a.m. – 9:00 a.m.) and afternoon peak (4:00 p.m. – 6:00 p.m.) commute hours.

  Construction truck traffic would arrive and depart during allowed construction hours (8:00 a.m. – 6:00 p.m.) (See MM NOI-1), deliveries would be staggered throughout the day as work occurs, and to the extent feasible, coordinated to arrive and depart at off-peak commute times.

  Once VAPP becomes operational, two VAPP operations employees are expected to be at the site at any given time, and there would be three shifts per day. As such, the site is estimated to generate twelve 1-way trips per day.

  As a result, the Proposed Project would not generate and/or cause a diversion or shift of 500 or more daily trips or 43 or more PM peak-hour vehicle trips on the street system. As such, no significant impacts to Intersection Capacity and Street Segment Capacity would occur and no further analysis is required.

[2] PM Peak hour is typically between 4:00 pm and 6:00 pm.

L.3. Freeway Capacity

- **Would the Proposed Project add 150 or more one-way vehicle trips to a Congestion Management Program (CMP) mainline freeway monitoring segment during either the AM or PM peak hours?**
- **Would the Proposed Project add 50 or more AM or PM peak-hour trips to a freeway on- or off-ramp?**

  According to the *L.A. CEQA Thresholds Guide* (2006), a "no" response to all of the preceding questions indicates that there would normally be no significant impact on Freeway Capacity from the Proposed Project. As previously stated, the number of trips generated by the project would be up to a total of 58 daily one-way vehicle trips as the worst-case scenario (up to 48 soil haul, 8 construction worker, and 2 other trips), but the trips would be distributed throughout the day and not all 58 vehicle trips would occur during the AM or PM peak hours. Once VAPP becomes operational, the site is estimated to generate twelve 1-way trips per day. Two staff members are expected to be at the site at any given time, and there would be three shifts per day. As a result, the Proposed Project would not add 150 or more one-way vehicle trips to a Congestion Management Program (CMP) mainline freeway monitoring segment during either the AM or PM peak hour and would not add 50 or more AM or PM peak-hour trips to a freeway on- or off-ramp. As such, no significant impacts to Freeway Capacity would occur and no further analysis is required.

L.4. Neighborhood Intrusion Impacts

- **Would the Proposed Project generate more than 120 daily vehicle trips to a local residential street?**

  According to the *L.A. CEQA Thresholds Guide* (2006), a "no" response to the preceding question indicates that there would normally be no significant impact on Neighborhood Intrusion from the Proposed Project. As previously stated, the number of trips generated by the project would be up to a total of 58 daily trips as the worst-case scenario. Once VAPP becomes operational, the site is estimated to generate twelve 1-way trips per day. Two VAPP operations employees are expected to be at the site at any given time, and there would be three shifts per day. As a result, the Proposed Project would not generate more than 120 daily vehicle trips to a local residential street. As such, no significant neighborhood intrusion impacts would occur and no further analysis is required.

L.5. Project Access

- **Would the Proposed Project generate and/or cause a diversion or shift of 500 or more daily trips or 43 or more PM peak-hour vehicle trips on the street system?**
- **Is a project driveway proposed on a major or secondary highway within 150 feet of an intersection with another major or secondary highway?**
- **Would a project driveway intersect an on-street bicycle lane or cross a sidewalk in an area of high pedestrian activity?**
- **Can it be readily perceived that there are access risks or deficiencies associated with the adjoining street system due to curves, slopes, walls or other barriers to adequate lines of sight?**

According to the *L.A. CEQA Thresholds Guide* (2006), a "no" response to the response to the first question and all of the following questions indicates that there would normally be no significant project access impacts from the Proposed Project. As previously stated, the number of trips generated by the project would be up to a total of 58 daily one-way vehicle trips as the worst-case scenario (up to 48 soil haul, 8 worker, and 2 other trips), but the trips would be distributed throughout the day and not all 58 vehicle trips would occur during the AM or PM peak hours. Therefore, it is assumed that the construction worker traffic would be before the morning and afternoon peak commute hours. Once VAPP becomes operational, the site is estimated to generate twelve 12-one-way trips per day. Two VAPP operations employees are expected to be at the site at any given time, and there would be three shifts per day. As a result, the Proposed Project would not generate and/or cause a diversion or shift of 500 or more daily trips or 43 or more PM peak-hour vehicle trips on the street system. In addition, the project driveway is not proposed on a major or secondary highway within 150 feet of an intersection with another major or secondary highway. Further, the project driveway does not intersect an on-street bicycle lane or cross a sidewalk in an area of high pedestrian activity. Lastly, there are no access risks or deficiencies associated with the adjoining street system due to curves, slopes, walls, or other barriers to adequate lines of sight. As such, no significant project access impacts would occur and no further analysis is required.

L.6. Transit System Capacity

- **Will an Environmental Impact Report (EIR) be prepared for the Proposed Project to evaluate potential transportation impacts?**

  This issue involves the potential impacts of the Proposed Project on the existing transit system ridership and capacity from the increased demand by project residents, employees, patrons, etc. According to the *L.A. CEQA Thresholds Guide* (2006), the determination of significance shall be made on a case-by-case basis, considering the projected number of additional transit passengers expected with implementation of the Proposed Project and available transit capacity. Because the Proposed Project does not generate more than 20 construction workers at any one time, and would include only six permanent employees once operational, no adverse impacts to transit capacity is expected. As such, no significant project impacts to transit capacity would occur and no further analyses is required.

L.7. Parking

- **Would the project's proposed parking supply be less than that required by City code, including Los Angeles Municipal Code (LAMC), Transportation Specific Plan (TSP) or Interim Control Ordinance (ICO) requirements, prior to applying for a variance, exemption, or amendment, if any apply to the project?**
- **If the project is located within the coastal zone (generally, 1,000 yards inland of the mean high tide line), would the project's proposed parking supply be less than that required by California Coastal Commission requirements?**

  According to the *L.A. CEQA Thresholds Guide* (2006), a "no" response to all of the preceding questions indicates that there would normally be no significant parking impacts from the Proposed Project. A project would normally have a significant impact on parking if the project provides less parking than needed as determined through an analysis of demand from the project.

Section 13 of the Venice Specific Plan specifically addresses parking standards and requirements as well as Beach Impact Zone parking requirements for new development within the Venice Coastal Zone. Within the Venice LCP, Policy II. A. 3. Parking Requirements, outlines parking requirements that shall apply to all new development. For a Public Utility Facility not having a Business Office on the premises, the parking requirement is to provide 2 spaces, plus 1 space for each 500 square feet of floor area. Additionally, the policy states that parking shall be provided pursuant to a detailed parking study that demonstrates that the project will provide adequate parking to meet the needs of the development without causing negative impacts to coastal access or access to public recreational facilities.

The Parking Assessment Memorandum dated October 3, 2016 prepared by Fehr & Peers addresses impacts to parking and is found in Appendix J of this Draft EIR. As noted below, that analysis determined that impact to parking from the Proposed Project would be less than significant.

Parking utilization surveys were conducted bi-hourly from 8:00 a.m. to 10:00 p.m. near the Project Site on a typical weekend day and a typical weekday (Saturday, September 12 and Thursday September 17, 2015). These days were selected to represent typical weekend and weekday conditions. Counts were collected of on-street public parking and one off-street public lot in a study radius of approximately 0.3 mile around the Project Site. The number of available parking spaces for each roadway segment or lot was inventoried at the beginning of data collection efforts. Parking utilization was separated between unrestricted parking and any restricted parking for a given location. The only time-restricted parking within the vicinity of the Project Site is the metered spaces located along Strongs Drive between Anchorage Street and Washington Boulevard, while the remaining spaces are only restricted per their respective scheduled street-sweeping and trash collection days.

Once construction begins, Hurricane Street will be permanently closed to traffic between Esplanade and Canal Court. This will result in the loss of five on-street parking spaces. Additionally, the segment of Canal Court adjacent to the project site will be temporarily closed during the construction period; however, parking is prohibited there.

The Venice Pumping Plant currently requires two employees per 8-hour shift (three shifts over a 24-hour period) and two parking spaces are located within the VPP site. Once VAPP becomes operational, this staffing level will remain unchanged. Thus VAPP/VPP would require up to four parking spaces at the peak time, when shift changes occur. Per the Venice Specific Plan and the Venice Local Coastal Program Land Use Plan, the project must also provide one space for Beach Impact Zone parking. The proposed project will construct eight off-street parking spaces at 128 Hurricane Street, which will fully satisfy the need for replacement parking (five spaces), employee parking (four spaces including the existing two off-street employee spaces within the VPP), and the one new space required as Beach Impact Zone parking.During the 2-year construction period of the VAPP, the loss of the five existing parking spaces from Hurricane Street between Canal Court and the Grand Canal would temporarily reduce the parking supply in the project vicinity. This will affect the convenience of drivers seeking to park, by reducing the total supply of on-street parking in the neighborhood around the VAPP site, although the total on-street parking in the vicinity could still accommodate these vehicles. The Parking Assessment Draft Memorandum concluded the existing available parking supply near the Project Site is sufficient under normal circumstances to accommodate the parking spaces that would be temporarily displaced during construction of the Proposed Project. In addition, within approximately 1,000 feet of the Project Site, at least 70 spaces were available during the

weekday peak period and at least 11 spaces were available during the busier weekend peak period. It is recognized, however, that during peak times on peak summer weekend days and weekdays and holidays, parking utilization is higher than what was observed on the survey dates. On those days, the temporary loss of these on-street spaces would be expected to result in an increase in vehicles circling through the neighborhood as they seek available parking. However, under normal operating conditions, this impact is less than significant.

With implementation of the proposed parking spaces, the project's parking supply would comply with City codes, plans, and ordinances. While the project is located within the coastal zone, the project's proposed parking supply would meet California Coastal Commission requirements. Upon project completion, the on-street parking on Hurricane Street east of Canal Court would be fully replaced off-street at 128 Hurricane Street. In addition, the proposed VAPP project, together with the existing VPP facility, would provide four employee parking spaces, sufficient to accommodate its needs, as well as one additional space as required for Beach Impact Zone parking. Thus, upon completion the project would result in one additional parking space in the project vicinity. As such, no significant project impacts to parking would occur and no further analysisis required.

L.8. In-Street Construction Impacts

- **Would a project not exempted in Article VII of the City CEQA Guidelines require construction activities to take place within a major or secondary highway ROW which would necessitate temporary lane, alley, or street closures for more than one day (including day and evening hours, and including overnight closures if on a residential street)?**
- **Would a non-exempt project require construction activities to take place within a collector or local street ROW which would necessitate temporary lane, alley, or street closures for more than seven days (including day and evening hours, and including overnight closures if on a residential street)?**
- **Would in-street construction activities result in the loss of regular vehicular or pedestrian access to an existing land use for more than one day, including day and evening hours and overnight closures if access is lost to residential units?**
- **Would in-street construction activities result in the temporary loss for more than one day of an existing bus stop or rerouting of a bus route that serves the Project Site?**

The Proposed Project does not require construction activities to take place within a major or secondary highway right-of-way that would necessitate temporary lane, alley, or street closures for more than one day.

The majority of construction traffic disruptions would occur on Hurricane Street and Canal Court, since a portion of both local streets would be temporarily closed. As such, construction would result in repeated overnight closures on a residential street. The Proposed Project would result in closure of a local street right-of-way, which would necessitate temporary lane, alley, or street closures for more than seven days.

In addition, pedestrian access to the Grand Canal from Hurricane Street would be temporarily restricted during construction and pedestrians would be diverted to Galleon Street to the north. Therefore, in-street construction activities would result in the loss of regular pedestrian access for more than one day.

In-street construction activities would not result in the temporary loss or relocation of an existing bus stop that serves the Project Site. The nearest bus stop, which is located to the west along Pacific Avenue, would not be affected.

According to the *L.A. CEQA Thresholds Guide* (2006), a "yes" response to any of the preceding questions indicates that further study may be required. As such, the Proposed Project could result in impacts from in-street construction, and this impact is discussed further below.

3.10.3.3 Thresholds of Significance

Thresholds of significance used in this EIR to analyze impacts are based on CEQA Appendix G and on the *L.A. CEQA Thresholds Guide* (2006).

According to Appendix G of the CEQA Guidelines, a project would normally have a significant impact on transportation and traffic if it would:

TRANS-1. Exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass

TRANS-2. Conflict with an applicable congestion management program, including, but not limited to, level-of-service standards and travel demand measures or other standards established by the county congestion management agency for designated roads or highways

TRANS-3. Result in inadequate emergency access

Based on the Initial Study and the Screening Criteria addressed above, the applicable thresholds of significance from the *L.A. CEQA Thresholds Guide* (2006) for Transportation and Traffic are as follows:

TRANS-4. L.8. In-Street Construction Impacts: The determination of significance shall be made on a case-by-case basis, considering the following factors:

- Temporary Traffic Impacts:
  - The length of time of temporary street closures or closures of two or more traffic lanes;
  - The classification of the street (major arterial, state highway) affected;
  - The existing traffic levels and level of service (LOS) on the affected street segments and intersections;
  - Whether the affected street directly leads to a freeway on- or off-ramp or other state highway;
  - Potential safety issues involved with street or lane closures; and
  - The presence of emergency services (fire, hospital, etc.) located nearby that regularly use the affected street.
- Temporary Loss of Access:
  - The length of time of any loss of vehicular or pedestrian access to a parcel fronting the construction area;
  - The availability of alternative vehicular or pedestrian access within ¼ mile of the lost access; and

- The type of land uses affected, and related safety, convenience, and/or economic issues.

- Temporary Loss of Bus Stops or Rerouting of Bus Lines:
  - The length of time that an existing bus stop would be unavailable or that existing service would be interrupted;
  - The availability of a nearby location (within ¼ mile) to which the bus stop or route can be temporarily relocated;
  - The existence of other bus stops or routes with similar routes/destinations within a ¼ mile radius of the affected stops or routes; and
  - Whether the interruption would occur on a weekday, weekend or holiday, and whether the existing bus route typically provides service that/those day(s).
- Temporary Loss of On-Street Parking:
  - The current utilization of existing on-street parking;
  - The availability of alternative parking locations or public transit options (e.g. bus, train) within ¼ mile of the Project Site; and
  - The length of time that existing parking spaces would be unavailable.

3.10.3.4 Construction Impacts

The analysis below describes the temporary impacts related to traffic and transportation anticipated as a result of the Proposed Project during construction.

The City of Los Angeles requires implementation of Worksite Traffic Control Plans (WTCPs) to ensure that any construction-related impacts are minimized to the greatest extent possible. These WTCPs typically require delineation of base conditions; construction impact areas; site-specific detour operations, such as traffic striping, pavement and curb markings; traffic control signs; signals; delineators; barricades; and traffic management requirements.

Some local streets, however, have weight limitations or restrictions that limit truck traffic. Typically, trucks would not travel on these streets except to obtain access to a specific site. The City of Los Angeles' policy is to allow trucks to travel in a "reasonable fashion" to and from a work site. The City of Los Angeles reviews each haul-route permit for specific application of its general guidelines. Trucks traveling to and from the site for the export of soil would use a specific haul route to Laydown Area 3, located at a City-owned property at 9940 Jefferson Boulevard in Culver City. It is expected that the haul route for soil export and import would follow Hurricane Street, Canal Court, Galleon Street, Pacific Avenue, Washington Boulevard, and Lincoln Boulevard.

TRANS-1. Exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit.

During construction of the Proposed Project, personnel, materials, and machinery would utilize the freeway system and local street system to access the site. Pacific Avenue, Canal Court, and Hurricane Street provide access to the Project Site and are residential collector streets that experience moderate to low traffic volumes during both day and evening peak-periods. During weekends and

summer months, these levels are elevated. There are no known exceedance capacities for pedestrian, bicycle paths, or the mass transit system associated with these streets or areas.

The entire Project Site would be fenced and Hurricane Street, between Canal Court and the Esplanade, would be permanently closed to the public. During Stage 1 of construction, a portion of Hurricane Street and Canal Court would be temporarily closed. Both Hurricane Street and Canal Court are narrow roadways that do not allow two vehicles to pass at the same time. This condition creates the need for drivers to wait to pass one another. Although during construction of the Proposed Project, procedures would be taken to ensure that all construction equipment, machinery, and construction personnel vehicles are kept off of these roadways, there is the potential for access to be blocked temporarily during loading and unloading activities or transport. At this stage of construction, pedestrian access along the Esplanade, Ballona Lagoon, and the Grand Canal would be maintained at Canal Court. However, pedestrian access to the Grand Canal from Hurricane Street would be eliminated; pedestrians would be diverted to Galleon Street to the north. The Esplanade would be re-opened to pedestrian access on the west side of the Grand Canal following completion of Stage 6 of construction. During the construction period at locations where construction activity would occur within public street right-of-way or in areas accessible to the public, increased safety risks to vehicles, bicyclists, and pedestrians could result from construction activities within or adjacent to affected sites due to narrowed lanes, altered travel patterns, and temporarily obstructed sidewalks.

Trip generation estimates that were prepared for the project were based upon projected staffing and vehicle activity levels. Trip generation estimates represent a worst-case scenario in that it considers the upper bounds of impacts likely to be experienced on the street system in the immediate vicinity of the site where construction activities could result in temporary lane closures and loss of on-street parking. It was found that the soil hauling during Stages 1 to 4 would generate the highest number of daily trips to and from the site. Preliminary analysis indicates that approximately 10,000 cubic yards of soil would need to be excavated from the site during Stages 1 and 2, including 2,300 cubic yards that would be exported to Laydown Area 1 and 7,700 cubic yards to be exported to Laydown Area 3. If needed, up to 3,850 cubic yards will be imported (returned) to the site for backfill during States 3 and 4. The balance of the exported soil is expected to be used as cover at an area landfill.

The anticipated peak estimate for the number of required truckloads for excavation is 48 one-way trips per day. The anticipated peak estimate for construction worker trips at the construction site is 6 trips per day. Including the 2 other trips for materials and equipment delivery, as mentioned above, a total of 58 daily trips is anticipated to be the worst-case scenario. The number of construction workers and construction equipment would actually vary throughout the construction process in order to maintain a reasonable schedule of completion. In addition, construction workers would be onsite at 7:00 a.m. and would typically leave the Project Site by 6:00 p.m. As a result, it is assumed that the construction worker traffic would occur during the morning and afternoon peak commute hours, but it would be considered negligible. Further, deliveries would be staggered throughout the day and coordinated to be delivered at off-peak commute times. Because construction worker traffic is negligible and material truck trips would be staggered through the day, traffic from construction trips is not expected to create a significant impact on the street system. While impacts are expected to be less than significant, incorporation of MM TRANS-1 Construction Worker Shuttles will ensure construction worker daily trips to the site are consolidated.

During the various construction phases of the project, travel by construction workers and truck hauling of supplies and disposal would generate trips on the regional and local transportation system surrounding construction site. These trips would represent temporary increases during

defined phases of construction and, upon completion of construction, would cease. The primary off-site impacts resulting from the movement of construction trucks would include a short-term and intermittent lessening of roadway capacities due to the slower movements and larger turning radii of the trucks compared to passenger vehicles. Drivers could experience delays if they were traveling behind a heavy truck. It is assumed that the soil hauling truck traffic would occur before the morning and afternoon peak commute hours. As such, the construction traffic impacts on the regional transportation network associated with the project would be short-term in nature and limited to the period of time when construction activity is taking place.

The added traffic would be most apparent on the local roadways serving the site, but as described above, this would be short-term in nature and the vehicle the trips would be distributed throughout the day (not all 58 vehicle trips would occur during the AM or PM peak hours). In addition, temporary street closures along Canal Court and Hurricane Street (see Chapter 2, Project Description) would not result in adverse traffic impacts on surrounding neighbors since alternate access would be available. Therefore, the Proposed Project would not exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit, and impacts would be **less than significant**; no mitigation measures are required.

TRANS-2. Conflict with an applicable congestion management program, including, but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways?

The CMP arterial monitoring intersection nearest to the Project Site is located at Lincoln Boulevard (SR 1) and SR 90 (Marina Expressway), which is approximately 1.2 miles to the northeast. Additionally, two additional arterial monitoring locations are located at the intersection of Lincoln Boulevard and Venice Boulevard (SR 187), approximately 1.3 miles to the northwest of the Project Site. As described above, the CMP requires analysis of traffic conditions at all CMP arterial monitoring intersections where the Proposed Project would add 50 or more trips during either the AM or PM weekday peak hours of adjacent street traffic. The CMP also requires that traffic studies analyze mainline freeway monitoring locations where the project would add 150 or more trips in either direction during either AM or PM weekday peak hours. As noted previously, the Proposed Project would add up to an estimated 58 daily trips, spread over an approximately 9-hour period, related to excavation, material deliveries, and worker commutes during the construction phase of the Proposed Project (construction hours are proposed to be Monday through Saturday from 8:00 a.m. to 6:00 p.m.; soil trucks are proposed to be at the Project Site only between 9:00 a.m. and 4:00 p.m. [see MM NOI-1]). As such, the project would not trigger a CMP analysis and implementation of the Proposed Project would not result in a potentially significant impact related to an applicable congestion management program, including, but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways. Therefore, impacts would be **less than significant**, and no mitigation measures are required.

TRANS-3. Result in inadequate emergency access

The entire Project Site would be fenced and Hurricane Street, between Canal Court and the Esplanade, would be permanently closed to the public. During Stage 1 of construction, a portion of Hurricane Street and Canal Court would be temporarily closed. Both Hurricane Street and Canal

Court are currently narrow roadways that do not allow two vehicles to pass at the same time. This condition creates the need for drivers to wait to pass one another. Construction activities would maintain this similar condition. During construction of the Proposed Project, procedures would be taken to ensure that all construction equipment, machinery, and construction personnel vehicles are kept off of these roadways. However, there is the potential for access to be temporarily blocked during loading and unloading activities or transport. As such, construction-related activities have the potential to result in temporary and periodic inadequate emergency access. Wherever possible, delivery trucks would be brought onto the Project Site and be loaded and unloaded within the perimeter fence of the construction site. To reduce the potential construction traffic impacts associated with the Proposed Project, Mitigation Measure MM-TRANS-2 would be implemented; this measure would require all construction activities to be conducted in accordance with an approved construction traffic control plan and requires advance notice to emergency service providers. This would serve to reduce the construction-related traffic impacts to the maximum extent feasible. MM TRANS-1 Construction Worker Shuttles would also help reduce construction-related traffic impacts on Hurricane Street. Therefore, construction of the Proposed Project would not result in inadequate emergency access and impacts would be **less than significant with mitigation**.

TRANS-4. L.8. Result in In-Street Construction Impacts

According to the *L.A. CEQA Thresholds Guide*, the determination of significance related to in-street construction shall be made on a case-by-case basis, considering several factors. These are each discussed below.

Temporary Traffic Impacts

The City of Los Angeles has established threshold criteria to determine significant traffic impacts of a Proposed Project in its jurisdiction. Although the methodologies and the criteria to calculate volume-to-capacity (V/C) ratios for intersections are intended by LADOT to identify potential traffic impacts during operation, they can also be applied to construction periods.

Under the City of Los Angeles guidelines, a project would be considered to significantly affect a local residential street if the projected increase in daily traffic volumes is as follows:

Projected Average Daily Traffic (ADT) with Project (Final ADT)	Project-Related Increase in ADT
0 to 999	120 or more
1,000 to 1,999	12% or more of final ADT
2,000 to 2,999	10% or more of final ADT
3,000 or more	8% or more of final ADT
Source: Fehr & Peers 2016.	

Based on these guidelines, VAPP construction activity would not result in any significant traffic impacts on study area streets because the maximum number of daily project trips is estimated to be 58 one-way trips (or 108 PCEs), which is below the minimum threshold volume considered significant. Therefore, the Proposed Project's in-street construction impacts related to temporary traffic impacts would be **less than significant**, and no mitigation measures are required.

Temporary Loss of Access

The entire Project Site would be fenced and Hurricane Street, between Canal Court and the Esplanade, would be closed to the public. During Stage 1 of construction, a portion of Hurricane Street and Canal Court would be temporarily closed and pedestrian access to the Grand Canal from Hurricane Street would be eliminated; pedestrians would be diverted to Galleon Street one block to the north or would be able to utilize Canal Court extending south to the Esplanade. Hurricane Street and Esplanade would be re-opened to pedestrian access on the west side of the Grand Canal following completion of Stage 6 of construction. Therefore, the Proposed Project would result in temporary loss of access impacts that would be **less than significant**; no mitigation measures are required**.**

Temporary Loss of Bus Stops or Rerouting of Bus Lines

The nearest bus stop to the Project Site is located at the corner of Pacific Avenue and Hurricane Street, approximately 0.7 mile to the west. Construction activities would not result in disruption to the existing bus stop or bus service, as no improvements would occur within the vicinity of the bus stop. Additionally, access to this bus stop would remain unchanged throughout project construction. Therefore, the Proposed Project **would not result in in-street construction impacts** related to temporary loss of bus stops or rerouting of bus lines; no mitigation measures are required**.**

Temporary Loss of On-Street Parking

As noted in the Parking Assessment Memorandum (Fehr & Peers 2016), within a study radius of 0.3 mile, there are an estimated 763 publicly available parking spaces, including 399 publicly available on-street spaces and 364 spaces at the public parking lot. This also includes 8 time-restricted parking spaces and 391 unrestricted parking spaces. During construction, a portion of Hurricane Street and Canal Court would be temporarily closed and parking spaces on Hurricane Street between Canal Court and the Esplanade would be unavailable. The loss of these spaces represents 0.65% of the total parking supply in the area.

Hurricane Street, where the Project Site is located, contains restricted on-street parking and parking is prohibited on Canal Court. There are approximately 19 parking spaces along Hurricane Street between Canal Court and Pacific Avenue. On weekend peak hours, parking on Hurricane Street is highly utilized and is greater than 85 percent. On weekday peak hours, parking on Hurricane Street is also highly utilized and is greater than 85 percent on the south side of the street but has a lower utilization less than 50 percent on the north side of the street. During construction, the loss of these on-street parking spaces would be expected to result in an increase in vehicles circling through the neighborhood as they seek available parking close to their residence. This impact could be adverse during peak hours, but is not considered to be significant because of the temporary nature of the construction activities. In addition, it is not considered significant because, within approximately 1,000 feet of the Project Site, at least 70 spaces are available during the weekday peak period and at least 11 spaces are available during the busier weekend peak period. It is noted however, that during peak times on peak summer weekend days and weekdays and holidays, it is recognized that parking utilization is higher than what was observed on the survey dates. On those days, the loss of these on-street spaces would be expected to result in a further increase in vehicles circling through the neighborhood as they seek available parking close to their destinations.

Because there is adequate supply during normal peak periods (the loss of these spaces represents less than 1% of the total parking within a 0.3-mile radius) and the loss of parking would be a temporary impact that would occur only during construction, as parking spaces would be provided at the 128 Hurricane Street lot upon completion of the Proposed Project, the Proposed Project **would not result in significant in-street construction impacts** related to loss of on-street parking, and no mitigation measures are required.

3.10.3.5 Operational Impacts

The analysis below describes the permanent impacts related to traffic and transportation anticipated as a result of the Proposed Project during operation.

TRANS-1. Exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit

The Proposed Project would require a total of six full-time employees, with two employees per shift working three consecutive eight-hour shifts. It is assumed that these employees would generally arrive two at a time to the job site via their personal automobiles and park at the 128 Hurricane Street lot. The addition of these twelve new one-way operation-related trips to the circulation and/or intersection or highway/freeway network would not generate levels that would exceed the capacity of these systems. Similarly, these trips would not exceed the capacity of the existing mass transit, pedestrian, or bicycle path system since adequate capacity currently exists and they would not generate sufficient trips to overwhelm these systems.

Pedestrian access to the Esplanade and the associated Grand Canal and Ballona Lagoon from Hurricane Street would be maintained during operations. Access during operations would also continue to be available from existing locations along Galleon Street and Canal Court. As such, implementation of the Proposed Project would not exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit. **Therefore, no adverse impacts would occur, and no mitigation is required.**

TRANS-2. Conflict with an applicable congestion management program, including, but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways

As described above, the CMP requires analysis of traffic conditions at all CMP arterial monitoring intersections where the Proposed Project would add 50 or more trips during either the AM or PM weekday peak hours of adjacent street traffic. The CMP also requires that traffic studies analyze mainline freeway monitoring locations where the project will add 150 or more trips in either direction during either AM or PM weekday peak hours. The Proposed Project would require two full-time employees (per shift) during operation, which would generate up to six new daily one-way trips. Implementation of the Proposed Project would not add 50 or more trips during either the AM or PM weekday peak hours of adjacent street traffic. As such, the Proposed Project would not result in a potentially significant impact related to an applicable congestion management program, including, but not limited to level of service standards and travel demand measures, or other

standards established by the county congestion management agency for designated roads or highways. **Therefore, no adverse impacts would occur, and no mitigation is required.**

TRANS-3. Result in inadequate emergency access

The roadways surrounding the Project Site would remain accessible during operation of the Proposed Project. In addition, the City requires that development plans be submitted to the City for review and approval to ensure that new development has adequate access, including driveway access and turning radius in compliance with existing City regulations. As such, operation-related activities do not have the potential to result in inadequate emergency access; **no impacts would occur, and no mitigation is required.**

TRANS-4. L.8. In-Street Construction Impacts

This threshold relates to construction impacts and does not apply to operational impacts. No further analysis is required.

3.10.4 Mitigation Measures

Proposed mitigation consists of the following measure to reduce the temporary adverse impacts associated with construction-period activity in the vicinity of the construction site. The implementation of the following mitigation measure would ensure that traffic/transportation impacts would be less than significant.

MM- TRANS-1: Construction Worker Shuttles

Construction workers would park at an off-site location and be shuttled to and from the Project Site each workday on 10 to 15-passenger shuttles or vans. While no specific off-site location has been identified at this time, it would likely lie within five miles of the Project Site. The selected contractor would be required to identify and secure a suitable location. In general, work is planned to occur between 8:00 a.m. and 6:00 p.m., and worker shuttles are expected to depart the site by 6:00 p.m.

MM-TRANS-2. Coordination with Emergency Service Providers

To minimize impacts on emergency access to the site during construction, the contractor, on behalf of the LABOE, shall coordinate with emergency service providers (police, fire, ambulance and paramedic services), prior to initiating construction, to provide advance notice of any lane closures, construction hours, and changes to local access and to identify alternative routes where appropriate.

3.10.5 Significant Unavoidable Adverse Impacts

There would be no significant unavoidable adverse impacts to traffic/transportation conditions due to implementation of the Proposed Project.

3.10.6 Cumulative Impacts

The study area for the cumulative traffic analyses encompasses the streets and roadways in the vicinity of the Project Site. Since the Proposed Project would result in no adverse operational traffic

or parking impacts, it would not contribute to any adverse cumulative operational impacts that could occur due to related growth and development, and no further discussion is required. With regards to cumulative traffic impacts during construction, eight related projects (see Chapter 1) have been identified in the study area. Only two of those projects, Via Dolce Park and Venice Dual Force Main, have identified construction schedules that would overlap with VAPP. As shown in Table 3.10-1, two of six study intersections were projected (2011) to operate at unacceptable levels of service of E or F during one or both peak hours. Construction traffic generated by the two related projects could result in additional congestion at these and other intersections in the project area. As discussed in the VAPP construction impact analyses above, the Proposed Project could generate up to 48 daily vehicle trips during the construction period. Those vehicle trips, combined with the construction vehicle trips due to the related projects, could cumulatively exacerbate already congested conditions at study area intersections. However, the impacts due to construction traffic would be temporary, and as noted above, the City of Los Angeles considers construction-related traffic impacts adverse but not significant because such impacts, while sometimes inconvenient, are only temporary. Therefore, the Proposed Project's contribution to significant cumulative traffic impacts during construction would not be cumulatively considerable.

3.11 Energy

This section describes the potential energy impacts of the Venice Auxiliary Pumping Plant (VAPP; Proposed Project). It includes a discussion of existing regulatory requirements, energy setting within the project area, and construction and operational energy requirements and associated impacts that would result from implementation of the Proposed Project. As noted in the analysis in this section, impacts during construction and operation would be less than significant and no mitigation measures are required.

3.11.1 Regulatory Setting

A review of the various federal, state, regional, and local government regulatory requirements was conducted to identify those related to energy. This section summarizes the various regulatory requirements that are relevant and applicable to the Proposed Project.

3.11.1.1 Federal Regulations

There are federal no laws or regulations related to energy applicable to the Proposed Project.

3.11.1.2 State Regulations

California Energy Commission

Created by the legislature in 1974, the California Energy Commission (CEC) is the state's primary energy policy and planning agency and is responsible for, among other things, forecasting future energy needs for the state. Senate Bill 1389 (Chapter 568, Statutes of 2002) requires the CEC to prepare a biennial Integrated Energy Policy Report. This report contains an integrated assessment of major energy trends and issues facing the state's electricity, natural gas, and transportation fuel sectors, and provides policy recommendations to conserve resources; protect the environment; ensure reliable, secure, and diverse energy supplies; enhance the state's economy; and protect public health and safety. The Commission adopted the 2015 Integrated Energy Policy Report on February 10, 2016.

3.11.1.3 Local Regulations

City of Los Angeles

Los Angeles Department of Water and Power: Power Integrated Resource Plan

Released to the public in December 2014, the Power Integrated Resource Plan identifies a portfolio of power generation resources and power system assets that would meet the City of Los Angeles' future energy needs, with the lowest cost and risk possible, consistent with the Los Angeles Department of Water and Power's (LADWP's) environmental priorities and reliability standards. Updates in the 2014 Power Integrated Resource Plan include new energy efficiency programs to achieve 15 percent energy efficiency savings by 2020, a Demand Response Implementation Plan with a goal to achieve 506 megawatts (MW) of demand response by 2026, and an energy storage procurement target of 178 MW by 2021 to support increased levels of renewable energy.

Building Construction Standards

Title 24 of the California Code of Regulations establishes energy conservation standards for new construction within the state of California. These standards are related to insulation requirements, glazing, lighting, shading, and water and space heating systems. The Los Angeles Municipal Code incorporates these state requirements (Section 91.1300).

The Los Angeles Green Building Code is based on the 2013 California Green Building Standards Code, commonly known as "CALGreen," which was developed and mandated by the state to attain consistency among the various jurisdictions within the state and reduce energy and water use, waste, and the overall carbon footprint in buildings. As of January 2011, all new buildings, additions, and building alterations for buildings valued at more than $200,000 are subject to the Green Building Code.

3.11.2 Environmental Setting

This section describes the environmental setting related to energy. It is intended to assist in the evaluation of impacts provided below and in the formation of required mitigation measures, if necessary.

LADWP provides electricity in the project area, as well as to approximately 1.4 million residential and business consumers in its service area. LADWP's service area includes a 465-square-mile swath in Los Angeles and the Owens Valley in the eastern Sierra Nevada region. Current electricity use is approximately 23,600 gigawatt-hours (GWh) annually. LADWP forecasts providing 24,000 GWh to customers in 2020 (LADWP 2014: p. 115).

The Project Site is currently vacant and as such, no public utilities serve the site. The adjacent Venice Pumping Plant (VPP) has 5 pumps (two duty and three backup), each of which has an 18-million-gallons-per-day (mgd) design capacity, which consumes approximately 6.5 million kWh per year based on an annualized 36-mgd flow (Arcadis 2016). The LADWP provides electrical service to the VPP, while natural gas service is provided by The Gas Company. In addition, VPP is served by a 1500-kW diesel generator and two parallel 750-kW diesel generators, which provide standby power in the event of loss of LADWP power or for maintenance purposes. The pumps and generators are the primary components of the VPP responsible for energy consumption, and the other equipment is responsible for minor amounts of energy use.

3.11.3 Environmental Impact Analysis

3.11.3.1 Methodology

Construction

The estimate of construction-related energy use was calculated by applying the U.S. Environmental Protection Agency– (EPA-) derived carbon dioxide equivalent (CO_2e) emissions per gallon of fuel to the total CO_2e emissions projected by the California Emissions Estimator Model (CalEEMod) in the air quality and GHG emissions analysis prepared for the Proposed Project. These calculations are included in Appendix B [Air Quality Emissions and Greenhouse Gas Calculations] of this EIR. Section 3.2, Air Quality, includes details on construction equipment and activity assumptions that were used to estimate CO_2e emissions. Emissions were then converted to million British thermal units (MMBTU) using energy unit conversion factors. Consistent with the GHG analysis methodology (see Section 3.6,

Greenhouse Gases of this EIR), the construction-period energy use was amortized over the expected 30-year life of the Proposed Project.

Operation

Based on information provided by the project design team (Arcadis), the proposed pumps at VAPP would be more efficient than the existing pumps at VPP. Because the Proposed Project would create redundancy to help ensure system reliability, the additional pumping capacity would not be needed except during wet-weather events. Assuming an annualized 36-mgd flow for the combined VPP and VAPP facility, there would be little change in overall energy consumption related to pumping. However, there would be an increase in energy consumption related to the operational control room, which would consume 570,000 kWh per year. Additional electricity consumption was assumed based on CalEEMod defaults, bringing the total electricity consumption to approximately 630,000 kWh annually (see Appendix B of this EIR) (Arcadis 2016). This figure was converted to MMBTU using energy unit conversion factors to allow for comparison with the energy use during the construction period. In addition to the electricity use from the Proposed Project, energy use from mobile, waste, and water sources would occur, which was calculated using the GHG output from CalEEMod (see Appendix B of this EIR). As was done for the construction period, CO_2e emissions were converted to gallons of fuel and MMBTU.

The discussion below identifies potential impacts from the Proposed Project and the measures that would be required to mitigate impacts that are found to be potentially significant.

3.11.3.2 Screening Analysis

As noted in Section Chapter 1.0, Introduction, the analysis and conclusions contained in the Initial Study (see Appendix A [Notice of Preparation/Initial Study] of this EIR) prepared for the Proposed Project considered and then eliminated a number of impacts from further analysis, including those contained in CEQA Appendix G and the *L.A. CEQA Thresholds Guide* (2006). Therefore, only those impacts and corresponding thresholds of significance noted below were determined to require further analysis and are addressed in this EIR.

3.11.3.3 Thresholds of Significance

According to the *L.A. CEQA Thresholds Guide*, the determination of significance with respect to energy impacts shall be made on a case-by-case basis, considering the following factors:

ENERGY-1. The extent to which the project would require new (off-site) energy supply facilities and distribution infrastructure, or capacity enhancing alterations to existing facilities;

ENERGY-2. Whether and when the needed infrastructure was anticipated by adopted plans; and

ENERGY-3. The degree to which the project design and/or operations incorporate energy conservation measures, particularly those that go beyond City requirements.

3.11.3.4 Construction Impacts

The analysis below describes the temporary and permanent impacts related to energy anticipated as a result of the Proposed Project during construction.

ENERGY-1. The extent to which the project would require new (off-site) energy supply facilities and distribution infrastructure, or capacity enhancing alterations to existing facilities

During the construction period, equipment and vehicles would be primarily powered by diesel fuel and would likely require minimal electricity. Table 3.11-1 shows the construction-period fuel use and equivalents in MMBTU, which would be 9,500 MMBTU over the entire period, or approximately 300 MMBTU when amortized over the anticipated 30-year life of the project.[1] Construction-period energy use includes energy that would be used in worker commute trips as well as haul trips and equipment use, which would result in the consumption of an estimated 66,000 gallons of fuel.

Although fuel would be consumed by construction vehicles and equipment, the fuel consumption would be temporary in nature and would represent a negligible increase in regional demand, and an insignificant amount relative to the more than 18 billion gallons of on-road fuels used in the state in 2013, an increase of approximately 0.000004 percent (California Energy Commission 2014). Given the extensive network of fueling stations throughout the project vicinity and the fact that the 2-year construction period would be short-term, no new or expanded sources of energy or infrastructure would be required to meet the energy demand associated with project construction. As such, construction impacts related to the extent to which the project would require new (off-site) energy supply facilities and distribution infrastructure, or capacity enhancing alterations to existing facilities would be **less than significant**, and no mitigation measures are required.

Table 3.11-1. Construction-Period Energy Use Estimate

	Diesel Fuel Use (gallons)	MMBTU
Overall Construction Energy Use	68,600	9,500
Amortized Construction Energy Use [a]	2,300	300

All figures have been rounded to the nearest 100.
[a] Construction energy use was amortized over the assumed 30-year life of the Proposed Project, consistent with the GHG analysis methodology
Source: CalEEMod modeling and conversion calculations by ICF 2016 (see Appendix B of this EIR).

ENERGY-2. Whether and when the needed infrastructure was anticipated by adopted plans

As discussed above, diesel fuel would be the primary energy source used during the construction period. Although there are no adopted local or regional plans regulating the supply and demand related fuels, given the extensive network of fueling stations throughout the project vicinity, the existing fuel infrastructure is expected to accommodate the increased construction-period demand for fuel introduced by the Proposed Project. Therefore, **no impact** would occur related to whether and when the needed infrastructure was anticipated by adopted plans, and no mitigation measures are required.

[1] Consistent with the methodology for GHG emissions, construction-period energy consumption is divided over the anticipated 30-year life of the proposed Project. Although construction would occur over a 2-year period, this method is intended to apportion the upfront energy consumption over the life of the proposed Project.

ENERGY-3. The degree to which the project design and/or operations incorporate energy conservation measures, particularly those that go beyond City requirements

There are no specific energy conservation measures proposed as part of construction activities. All equipment would be used in compliance with the manufacturer's specifications. As such, construction of the Proposed Project is not expected to result in the wasteful or inefficient use of energy. Therefore, impacts related to the degree to which the project design and/or operations incorporate energy conservation measures, particularly those that go beyond City requirements would be **less than significant**, and no mitigation measures are required.

3.11.3.5 Operational Impacts

ENERGY-1. The extent to which the project would require new (off-site) energy supply facilities and distribution infrastructure, or capacity enhancing alterations to existing facilities

Project operation would involve the use of electricity to power pumps and equipment (such as computers, servers, and mechanical systems), as well as to provide lighting. Energy would also be used in the transport of potable water and solid waste associated with the electrical building and as fuel in 3 employee vehicles commuting to and from the Project Site on a daily basis. Table 3.11-2 shows the energy requirements of the Proposed Project and the equivalents in MMBTU, which would be 3,100 MMBTU annually. Diesel use by the backup generator and by maintenance vehicles at the site was not quantified, as it would be an infrequent occurrence of limited duration. However, this energy consumption would be a nominal addition to the regular energy use identified in Table 3.11-2.

Table 3.11-2. Operational Energy Use Estimate

	Annual Energy	Annual MMBTU
Existing Energy Use		
Electricity (VPP only)	6.5 Million kWh	22,100
Proposed Project Energy Use		
Electricity (VAPP only)	632,400 kWh[a]	2,200
Natural Gas		200
Mobile	1,200 gallons fuel	300
Waste	12.4 tons[b]	100
Water	2.3 million gallons[b]	300
	Total Proposed Increase	*3,100*

All MMBTU figures have been rounded to the nearest 100.
[a] Based on the sum of the 570,000 kWh estimate provided by Arcadis and CalEEMod defaults for miscellaneous electricity requirements (lighting, heating and cooling, etc.)
[b] CalEEMod output provided based on default square footage building type.
Source: CalEEMod modeling and conversion calculations by ICF 2016 (see Appendix B of this EIR).

As discussed in Chapter 2, Project Description, new tie-ins to LADWP electricity sources would be required for project operation. The electricity required annually for operation of the pumps and electrical building would constitute a new energy demand and would increase the consumption of electricity in the LADWP service area relative to existing conditions. However, this project-related increase of approximately 630,000 kWh (2,200 MMBTU) represents a very small portion (approximately 0.00003 percent) of the 24,000 GWh (82 million MMBTU) of electricity that LADWP

forecasts providing to customers in 2020 (LADWP 2014: p. 115). It is anticipated that LADWP would be capable of meeting the electricity demands of the Proposed Project and that the Project would not require new electricity infrastructure beyond that which is existing or has been previously planned. Similarly, the Proposed Project's demand for natural gas (approximately 200 MMBTU, according to estimate calculated in Appendix B of this EIR) would be able to be met by existing supplies provided by The Gas Company. The Proposed Project is consistent with City and countywide efforts to maintain and improve the wastewater collection system. Therefore, impacts related to the extent to which the project would require new (off-site) energy supply facilities and distribution infrastructure, or capacity enhancing alterations to existing facilities would be **less than significant**, and no mitigation measures are required**.**

ENERGY-2. Whether and when the needed infrastructure was anticipated by adopted plans

As discussed in Section 3.2, Air Quality, the Proposed Project is consistent with the wastewater provisions contained within the Framework Element of the City of Los Angeles General Plan. In addition, The Bureau of Engineering has programmed the Proposed Project as part of its Wastewater – Collection System Program (City of Los Angeles 2016). LADWP has adopted the Power Integrated Resource Plan to manage the electricity needs of the City's inhabitants, which includes energy used for wastewater pumping.

Thus, the improvements proposed by the Project have been identified as needed infrastructure in adopted plans. Therefore, impacts related to whether and when the needed infrastructure was anticipated by adopted plans would be **less than significant** and no mitigation measures are required.

ENERGY-3. The degree to which the project design and/or operations incorporate energy conservation measures, particularly those that go beyond City requirements

The objective of the Proposed Project is to provide redundancy for increased system reliability and pumping capacity to the reduce risk of sewage overflows during extreme wet weather events. Energy conservation has been incorporated into the Proposed Project design through use of variable frequency drives (VFD) for the pumps. VFD will adjust motor speed to vary discharge flows, allowing for the most efficient pump operation. The electrical building would also be constructed in compliance with all applicable provisions of the City of Los Angeles Building Code, which includes the provisions of the Green Building Code. Despite the purpose of the Proposed Project to achieve redundancy and capacity increases, the Proposed Project would be as efficient as possible; Therefore, impacts related to the degree to which the project design and/or operations incorporate energy conservation measures, particularly those that go beyond City requirements would be **less than significant**, and no mitigation measures are required.

3.11.4 Mitigation Measures

No mitigation measures are required.

3.11.5 Significant Unavoidable Adverse Impacts

There would be no significant unavoidable impacts related to energy either during construction or operation of the Proposed Project.

3.11.6 Cumulative Impacts

As discussed above, the energy use that would result from implementation of the Proposed Project would be negligible relative to the regional market. However, the increased electricity consumption associated with the Proposed Project in combination with future projects within LADWP's service area may require new electricity transmission infrastructure or the rehabilitation of existing electricity infrastructure to meet that increased demand and maintain adequate levels of service, notwithstanding future savings resulting from increased energy efficiency. Although LADWP has planned for long-term increases in demand, new supply and delivery infrastructure facilities could be required to meet increased regional demands. Where LADWP has identified specific individual projects that are required to meet future projected regional cumulative demands and determined that construction or operation of those projects would result in significant impacts to the environment, then the cumulative impact of the Proposed Project and other projects in the LADWP service area would be considered significant. Therefore, for the purposes of this EIR, it is concluded that the Proposed Project could result in a cumulatively considerable contribution to a potentially significant cumulative energy impact.

Chapter 4
Comparison of Alternatives

4.1 Introduction

State CEQA Guidelines Section 15126.6 requires that an EIR describe a range of reasonable alternatives to a project that could feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any significant environmental impacts. According to the State CEQA Guidelines, the EIR should compare merits of the alternatives and determine an environmentally superior alternative. The range of alternatives discussed in an EIR is governed by the "rule of reason," which requires the identification of only those alternatives necessary to permit a reasoned choice between the alternatives and the proposed project. An EIR need not consider an alternative that would be infeasible. State CEQA Guidelines Section 15126.6(f)(1) explains that the evaluation of project alternative feasibility can consider "site suitability, economic viability, availability of infrastructure, general plan consistency, other plans or regulatory limitations, jurisdictional boundaries, and whether the proponent can reasonably acquire, control, or otherwise have access to the alternative site." The EIR is also not required to evaluate an alternative that: (1) has an effect that cannot be reasonably identified or that has remote or speculative implementation and (2) would not achieve the basic project objectives.

4.2 CEQA Alternatives

Pursuant to the CEQA requirements identified in Section 4.1 above, alternatives to the Proposed Project were developed for this EIR that would obtain many or most of the objectives of the Project and would avoid or substantially lessen one or more of the Proposed Project's significant environmental impacts.

The basic objectives of the Proposed Project are:

- Prevent potential impacts on human and environmental health caused by sewage spills from the existing Venice Pumping Plant during extreme wet-weather events;
- Increase reliability to the system by providing redundancy to pumping capacity to improve system reliability and to allow regular service and maintenance activities to take place without compromising the ability of the City of Los Angeles (City) to maintain pumping capacity and minimize the risk of sewage overflows; and
- Address future risks related to climate change, including increased storm intensities and sea level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP.

The Proposed Project would result in the following significant and unavoidable impacts:

- Noise and Vibration – during construction activities, impacts related to noise and vibration would be significant and unavoidable, despite the application of mitigation measures.

- Land Use – during construction activities, secondary impacts to surrounding land uses would occur related to noise and vibration. These impacts would be significant and unavoidable, despite the application of mitigation measures.

Based on the above, the following alternatives to the Proposed Project have been identified:

- No Project/No Build Alternative
- Alternative 1 – Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade

These alternatives are described below.

4.2.1 No Project/No Build Alternative

As required by CEQA Guidelines Section 15126.6 (e), under the No Project/No Build Alternative, the Proposed Project would not be implemented. The existing Venice Pumping Plant (VPP) would operate in its current condition with normal and planned upgrades and maintenance. Rental of temporary pumps and associated piping and back-up generators would be undertaken, as needed to address extreme wet-weather or dry weather events and/or when existing pumps are either down or undergoing maintenance (up to three pumps and two diesel generators). As in the past, temporary pumps and piping would be located at-grade within Hurricane Street between Canal Court and Esplanade. There is a minimum three-week set up time to bring the equipment on-line. Hurricane Street (between Canal Court and Esplanade) would be closed to the public during this time period. The equipment would operate 24 hours per day.

4.2.2 Alternative 1 – Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade

This alternative would be identical to the Proposed Project, except that Hurricane Street would be permanently vacated between Canal Court and Esplanade. Both coastal access and existing parking would be eliminated and no public access to the Venice Auxiliary Pumping Plant (VAPP; Proposed Project) or existing VPP would be allowed. The site would be fenced and controlled via secured and gated access.

4.2.3 Alternatives Considered but Rejected As Infeasible

Section 15126.6(c) of the State CEQA Guidelines requires EIRs to identify any alternatives that were considered by the lead agency but were rejected as infeasible during the scoping process, and briefly explain the reasons underlying the lead agency's determination.

4.2.3.1 Use of Temporary At-grade Pumps with External Piping at Venice Pumping Plant and/or Along Hurricane Street

This alternative would include the periodic and temporary use (e.g., Fall through Spring or potentially year round) of rented pumps (three) and associated external piping and back-up diesel generators (three) installed at-grade and on-site within the existing VPP and/or within Hurricane Street (between Canal Court and Esplanade, in lieu of the Proposed Project Site). A new Control

Room would be installed at the VPP. In addition, there is a minimum three-week set up time to bring the equipment on-line. Hurricane Street (between Canal Court and Esplanade) would be closed to the public during this time period. The equipment would operate 24 hours per day. It would also require the demolition of the existing Concrete Masonry Unit (CMU) on top of the newly constructed Venice Manifold (located along Hurricane Street between Canal Court and Esplanade).

Preliminary evaluations indicate that there is little or no available space to house the required pumps and associated piping and back-up generators on-site at the VPP and as such, all equipment would likely need to be installed along Hurricane Street between Canal Court and Esplanade. Since the Venice Manifold Project is currently installed within Hurricane Street any maintenance or repairs to that facility would require removal of the temporary pump equipment and its re-installation. This could result in system operation issues and compromise required redundancies, potentially resulting in catastrophic failure, requiring emergency discharges directly to the Grand Canal and Ballona Lagoon or overflows into the surrounding street network. A preliminary analysis indicates that there is no space available in the existing VPP Control Room to allow for construction of new control facilities. System operation and safety could also potentially be compromised during testing and migration of the control system. This alternative would reduce future risks related to climate change, including increased storm intensities and sea level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP. It would also provide the required redundancy needed to operate the facility safely and reduce the potential for catastrophic failure. However, as noted below, it would not be able to obtain the required design capacity of 87 million gallons per day (mgd).

Because there is little available space, it is unclear if operational or safety issues would be adequately addressed, including redundancy or sewage bypass capabilities. Similar to the No Build Alternative, this alternative depends on temporary, in lieu of permanent pumping facilities and associated piping and back-up generators in a provisional location and does not solve the long-term needs of the VPP. The use of these pumps and associated equipment in an outdoor environment are also expected to result in more frequent maintenance, breakdowns, and repairs. The anticipated combined pumping capacity of the five existing pumps at the VPP and the three temporary pumps would be between 60 and 65 mgd, which would be below the required design capacity of 87 MGD.

In addition to lack of space to construct the required improvements, the pumps would be required to operate 24-hours per day, seven-days per week, continuously and outdoors along Hurricane Street within a residential neighborhood. Their operation would also likely produce unacceptable noise levels, nuisance odors, and adverse air quality (diesel emissions from the back-up generators), which could affect adjacent sensitive receptors.

The number of near-misses and associated potential for catastrophic failure at the VPP have increased since the 1990s and is expected to worsen, due to climate change and associated sea-level rise and increased storm intensity and frequency. The current VPP does not have standard redundancies in place to address pump failure or required maintenance and therefore, cannot divert flows from the coastal interceptor sewer (CIS) collection area (see Chapter 2, Project Description of this EIR). In the event of catastrophic failure, untreated sewage flows would need to be diverted to the Grand Canal and Ballona Lagoon, both of which are designated as Sensitive Ecological Areas. In addition, the VPP does not contain a modern Control Room, which is needed for flow and pump monitoring.

This alternative could result in potential health and safety risks to area residents and wildlife.

4.2.3.2 Build new Plant on Proposed Site and Decommission and Demolish existing Venice Pumping Plant

This alternative would entail the construction of a new pumping plant on the Proposed Project Site and then decommissioning and demolishing of the existing plant. The new facility would be designed to handle the operational design capacity of the VPP and Proposed VAPP (87 mgd), as described for the Proposed Project (see Chapter 2, Project Description of this EIR) and would meet some, but not all of the project objectives. The lot of the demolished VPP would be converted to an open space area to enhance coastal access.

This alternative would not minimize the potential for sewage spills from the existing VPP because the two available parcels would not be able to physically accommodate the Proposed Project's electrical building and eight pumps (even if submersible pumps were assumed, which have a reduced footprint) required to meet the design capacity of 87 mgd. During extreme wet-weather events, it would not prevent potential impacts on human and environmental health due to the risk of sewage spills from the existing VPP. Moreover, this alternative would not satisfy the objective of providing redundancy to pumping capacity to improve system reliability and allow regular service and maintenance activities to take place without compromising the City's ability to address issues related to the risk of sewage overflows. It would also not address future risks related to climate change, including increased storm intensities and sea- level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP.

As noted above, there is insufficient space to construct a new plant and associated eight pumps on the two available parcels proposed for the VAPP and therefore, this alternative would not avoid severe operational and safety problems.

A new pumping plant cannot be physically constructed within the two available parcels, despite the installation of submersible pumps. As such, this alternative does not avoid unacceptable adverse social, economic or environmental impacts since it would not solve the VPP's long-term pumping capacity needs. It would also not allow for routine maintenance of pumps, which requires that they be taken off-line for service or in the event of pump failure (including multiple pumps), the ability of the system to have adequate back up or redundancy. Therefore, this alternative would not allow for avoidance of a catastrophic sewage spill into the Grand Canal and Ballona Lagoon, resulting in potential environmental damage and health and safety issues.

This alternative could result in potential health and safety risks to area residents and wildlife.

4.2.3.3 Expand Existing Venice Pumping Plant and Install Pumps and Piping Below-grade

This alternative would entail installation of three permanent pumps and associated piping underground and would require expansion of the existing VPP. Since the Venice Manifold Project is located within Hurricane Street and the Grand Canal and Ballona Lagoon are located to the east and south, respectively, expansion would be limited to the west within Canal Court and the adjacent vacant City-owned parcel at 128 Hurricane Street. Although the exact configuration of the design is not known, it is likely that installation of the three new pumps and associated piping would occur underground within Canal Court (between Hurricane Street and Esplanade). The back-up diesel generators would likely be installed within the adjacent vacant parcel at 128 Hurricane Street. It is not clear where the diversion structure between the VPP and the CIS would be located and

therefore, additional investigation is required. A new Control Room would be installed at the VPP (pending elimination of the existing one), within the adjacent vacant parcel at 128 Hurricane Street, or off-site at the Hyperion Treatment Plant in Playa del Rey.

This alternative would not minimize the potential for sewage spills from the existing VPP, provide redundancy to pumping capacity, and allow regular maintenance activities to occur, and would not address future risk related to climate change, including increased storm intensities and sea-level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP. This alternative has several inherent challenges and problems (see discussion below).

This alternative has several design and operational challenges that would need to be addressed to ensure that the VPP can be safely operated during construction. In particular, substantial modifications to the existing VPP would be required, necessitating taking it off-line for an extended period and the installation of temporary pumps. Because there is currently no by-pass mechanism for sewage flows from the CIS, this cannot be done since the VPP is required to pump sewage continually to avoid a catastrophic spill event or back-up into the Grand Canal, Ballona Lagoon, or adjacent street network. In addition, the CIS is located on the east side of the VPP and therefore, the existing wet well would have to be expanded to the west to make the connection. This would require extensive modifications to the existing VPP. Moreover, extensive modifications would be required in order to connect to the Venice Manifold (located within Hurricane Street between Canal Court and Esplanade) and to access the existing wet well. It is unclear if this would be structurally feasible. Maintenance of the pumps would also be problematic due to access. It should also be noted that the Venice Manifold has been designed and constructed to accommodate the VAPP from the two available vacant parcels (proposed Project Site) and the future connection to the CIS.

Because no sewage by-pass exists and therefore, the VPP cannot be taken off-line, the implementation of this alternative could result in a catastrophic system failure resulting in sewage spills to the Grand Canal and Ballona Lagoon and adjacent street network. Such an event could endanger the health and safety of area residents and wildlife.

4.2.3.4 Construct VAPP Underground at Proposed Project Site Location with Control Room Located Off-site

This alternative would be identical to the Proposed Project and would entail the construction of permanent pumps and associated piping underground within the Proposed Project Site. The back-up diesel generators would likely be constructed in an enclosed housing and at-grade. However, the new Control Room would be located off-site and possibly at the Hyperion Treatment Plant in Playa del Rey.

This alternative would minimize the potential for sewage spills from the existing VPP, provide redundancy to pumping capacity and allow regular maintenance activities to occur, and would address future risk related to climate change, including increased storm intensities and sea-level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP.

This alternative would result in increased safety issues since the proposed facility would be un-manned and controlled remotely via a Control Room located at an off-site location, potentially within the Hyperion Treatment Plant. Ideally, the control room should be located on-site since this is a critical City facility. Moreover, this is the only collection and pumping station that is staffed 24

hours per day 365 days per year. There are also hard-wired systems that need to be monitored by staff continuously.

The absence of on-site staff and remote control of the plant increases the potential risk for catastrophic system failure and potential for a sewage spill that could affect the health and safety of adjacent residents and wildlife. The presence of staff on-site increases plant safety through physical monitoring and assessment of the system's capacity and performance.

4.2.3.5 Construct Auxiliary Pumping Plant at Alternate Location along Coastal Interceptor Sewer

This alternative would entail construction of permanent pumps and associated piping and back-up generators at an alternate location along the Coastal Interceptor Sewer. A new Control Room would be installed on-site at this location. In addition, a new force main would be required.

This alternative would not minimize the potential for sewage spills from the existing VPP, provide redundancy to pumping capacity, and allow regular maintenance activities to occur, and would not address future risk related to climate change, including increased storm intensities and sea-level rise, which have the potential to result in flows that would be beyond the capacity of the existing VPP.

The VPP is located at a "low-point" in the CIS conveyance system and must pump sewage underneath and across the Marina del Rey channel and then to the Hyperion Treatment Plant (located Playa del Rey), which entails an elevational difference of some 60 feet. Relocating the auxiliary pumps and diversion structure outside of this area would not provide the necessary hydraulic capacity and redundancy needed during wet-weather or extreme weather events and therefore, could result in a catastrophic spill events or back-up into the Grand Canal, Ballona Lagoon, or street network. This alternative could result in potential health and safety risks to area residents and wildlife.

4.2.3.6 Summary

On December 1, 2015 and on June 11, 2016, the City of Los Angeles, Bureau of Engineering and its design team conducted Project Development Team (PDT) meetings to develop, evaluate, and screen project alternatives. This was undertaken in order comply with CEQA and develop a reasonable range of alternatives for consideration in the Draft Environmental Impact Report (Draft EIR). The process was completed in two stages: (1) consultant development of potential alternatives for analysis and discussion; and (2) evaluation of feasible and infeasible alternatives. This information was then used by the PDT to refine the alternatives into what is now the Proposed Project that is described in Chapter 2 and evaluated in Chapter 3 of this EIR.

4.3 Evaluation of CEQA Alternatives

The impacts of each of the alternatives are briefly described below and are compared to the impacts of the Proposed Project. The analysis includes a discussion of a No Project/No Build Alternative as required under Section 15126(e)(1) of the State CEQA Guidelines so that decision-makers can compare the impacts of approving the Proposed Project with the impacts of not approving the Proposed Project. Other than the No Project/No Build Alternative, each of these alternatives would

meet most of the Proposed Project objectives described in Chapter 2, but only the Proposed Project meets them all. In addition, any alternatives that would result in less-than-significant impacts with mitigation that are similar to the Proposed Project, would be required to comply with the same mitigation measures as would be implemented for the Proposed Project.

4.3.1 No Project/No Build Alternative

Since the Proposed Project would not be implemented, short-term unavoidable significant impacts related to construction noise and vibration and land use and planning (related to construction noise and vibration) or potentially significant cumulative impacts associated with energy would not result. In addition, there are currently no diversions for bypassing the VPP and the pumping plant must continuously pump sewage flows from the CIS in order to avoid sewage backups. As such, this alternative would not provide the required redundancy needed to operate the VPP safely and reduce the potential for catastrophic failure. It would also not reduce future risks related to climate change, including increased storm intensities and sea level rise, which have the potential to result in flows that would be beyond the capacity of the existing facility and could result in potentially significant impacts related to health and safety and wildlife (due to a catastrophic sewage spill in the adjacent street system and Grand Canal and Ballona Lagoon). Because this alternatives would require the periodic rental and placement of pumps along Hurricane Street (between Canal Court and Esplanade), required to operate 24-hours per day, seven-days per week, these activities would produce unacceptable noise levels and nuisance odors and air quality (diesel emissions from the back-up generators) on adjacent sensitive receptors. None of the Proposed Project's objectives would be met by this alternative.

4.3.2 Alternative 1 – Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade

4.3.2.1 Aesthetics

Impacts would be similar to the Proposed Project.

4.3.2.2 Air Quality

Impacts would be similar to the Proposed Project.

4.3.2.3 Biological Resources

Impacts would be similar to the Proposed Project.

4.3.2.4 Cultural Resources

Impacts would be similar to the Proposed Project.

4.3.2.5 Geology and Soils

Impacts would be similar to the Proposed Project.

4.3.2.6 Greenhouse Gas Emissions

Impacts would be similar to the Proposed Project.

4.3.2.7 Hydrology and Water Quality

Impacts would be similar to the Proposed Project.

4.3.2.8 Land Use

Impacts would be similar to the Proposed Project, although a street vacation permit would be required and Hurricane Street between Canal Court and Esplanade would be permanently closed to the public and parking eliminated. The street vacation would not be consistent with California Coastal Commission policies regarding coastal access and parking. To address the elimination of existing street parking along Hurricane Street in this area, a total of eight parking spaces would be provided at 128 Hurricane Street, immediately west of the VPP. Although pedestrian access along Hurricane Street between Canal Court and Esplanade would be eliminated, additional alternate access would be available via Canal Court and Galleon Street. Therefore, impacts would be less than significant and no mitigation measures are required.

4.3.2.9 Noise & Vibration

Impacts would be similar to the Proposed Project.

4.3.2.10 Transportation/Traffic

Impacts would be similar to the Proposed Project. Hurricane Street extending from Canal Court to Esplanade would be permanently closed to the public and parking eliminated. To address the elimination of existing street parking along Hurricane Street in this area, a total of eight parking spaces would be provided at 128 Hurricane Street, immediately west of the VPP. Although pedestrian access along Hurricane Street between Canal Court and Esplanade would be eliminated, additional alternate access would be available via Canal Court and Galleon Street. Therefore, impacts would be less than significant and no mitigation measures are required related to access. In addition, as with the Proposed Project, with the implementation of mitigation measures, direct and indirect impacts associated with transportation/traffic conditions during construction and operation of the Proposed Project would be less than significant.

4.3.2.11 Energy

Impacts would be similar to the Proposed Project.

4.3.2.12 Project Objectives Met

Under this alternative, all project objectives would be met, similar to the Proposed Project. Impacts during both construction and operation would be similar to the Proposed Project with the exception of pedestrian and vehicular access. Under this alternative, Hurricane Street between Canal Court and Esplanade would be vacated (closed) and public access permanently eliminated. This project component would reduce available area parking to residents and beach-goers along Hurricane Street between Canal Court and Esplanade. However, alternate parking (totaling 8 spaces) would be made available at 128 Hurricane Street (vacant parcel immediately west of the VPP). In addition, as

noted in Section 3.10, Transportation and Traffic of this EIR (see also Appendix J [Parking Memorandum] of this EIR), the elimination of these parking spaces would result in less than significant impacts and no mitigation is required. Moreover, alternate pedestrian access to Esplanade (see Figure 2-2, Chapter 2 [Project Description] of this EIR) would be available via Canal Court and Galleon Street, although this would be slightly more circuitous for some residents/visitors. Because alternate access would be available to the Grand Canal and Ballona Lagoon, impacts would be less than significant related to coastal access.

4.4 Comparison of CEQA Alternatives

Table 4-1 provides a comparison of the Proposed Project, No Project/No Build Alternative and Alternative 1. As noted below, the Proposed Project and Alternative 1 have similar impacts with the majority being less than significant or less than significant impacts with mitigation. In both cases for noise and vibration, impacts would be Significant and Unavoidable (construction only) as would land use and planning (construction only and related to noise and vibration), while cumulative energy impacts are potentially significant. In the case of the No Project/No Build Alternative, while impacts would be less than significant for the majority of environmental topics, they would be potentially significant and adverse for both Biological Resources and Hydrology and Water Quality since the existing VPP has been subject to near catastrophic failure due to insufficient pumping capacity during extreme wet-weather events in which multiple pumps have failed, were being repaired, or undergoing maintenance.

Table 4-1. Comparison of Proposed Project and Alternatives

	Alternatives		
Environmental Resource	Proposed Project	No Project/No Build Alternative	Alternative 1- Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade
Aesthetics			
	Less than Significant Impact with Mitigation	Environmentally Superior	Less than Significant Impact with Mitigation
Air Quality			
	Less than Significant Impact with Mitigation	Environmentally Superior	Less than Significant Impact with Mitigation
Biological Resources			
	Less than Significant Impact with Mitigation	Potentially Significant and Adverse	Less than Significant Impact with Mitigation
Cultural Resources			
	Less than Significant Impact with Mitigation	Environmentally Superior	Less than Significant Impact with Mitigation
Geology and Soils			

	Alternatives		
Environmental Resource	Proposed Project	No Project/No Build Alternative	Alternative 1- Construct Venice Auxiliary Pumping Plant and Permanently Vacate Hurricane Street between Canal Court and Esplanade
	Less than Significant Impact with Mitigation	Environmentally Superior	Less than Significant Impact with Mitigation
Greenhouse Gas Emissions			
	Less than Significant	Environmentally Superior	Less than Significant
Hydrology and Water Quality			
	Significant and Unavoidable (operation only and related to tsunami and sea level rise)	Potentially Significant and Adverse	Significant and Unavoidable (operation only and related to tsunami and sea level rise)
Land Use and Planning			
	Significant and Unavoidable (construction only and related to noise and vibration)	Environmentally Superior	Significant and Unavoidable (construction only and related to noise and vibration)
Noise and Vibration			
	Significant and Unavoidable (construction only)	Environmentally Superior	Significant and Unavoidable (construction only)
Transportation and Traffic			
	Less than Significant Impact with Mitigation	Environmentally Superior	Less than Significant Impact with Mitigation
Energy			
	Less than Significant (significant and unavoidable cumulative impact)	Environmentally Superior	Less than Significant (significant and unavoidable cumulative impact)

4.5 Environmentally Superior Alternative

In addition to the discussion and comparison of impacts of a proposed project and its alternatives, Section 15126.6 of the State CEQA Guidelines requires that an "environmentally superior" alternative be identified and the reasons for such a selection be disclosed. In general, the environmentally superior alternative is the alternative that would be expected to generate the least

amount of adverse impacts. In this case, as detailed above and shown in Table 4-1, the No Project/No Build Alternative would result in the fewest impacts on the existing environment. It should be noted however, that the No Project/No Build Alternative could result in catastrophic failure since the VPP has experienced near-miss conditions that would have resulted in discharges of sewage to the Grand Canal, Ballona Lagoon, or adjacent street system (see Chapter 2, Project Description of this EIR for more detail).

Pursuant to CEQA regulations (see CEQA Guidelines Section 15126.6(e)(2)), when the No Project Alternative is identified as the environmentally superior alternative, the EIR shall also identify an environmentally superior alternative from among the other alternatives. To determine which of the other alternatives would be environmentally superior, the analysis focused on those Proposed Project impacts identified as significant and unavoidable. As noted in Table 4-1, impacts associated with the Proposed Project and Alternative 1 would be similar. The differences between these two are minor since both alternatives would eliminate parking along Hurricane Street between Canal Court and Esplanade and provide alternate parking at 128 Hurricane Street. In the case of the Proposed Project, although Hurricane Street would not be vacated, red striping of the curb would occur, thereby eliminating these spaces permanently from public use. Similarly, under Alternative 1, the vacation of Hurricane Street would also permanently remove these spaces. In the case of pedestrian access, the Proposed Project would maintain access along Hurricane Street between Canal Court and Esplanade, while Alternative 1 would permanently eliminate it. Although alternate access to the Esplanade would be available via Canal Court and Galleon Street, access would be more circuitous to residents/visitors. As such, the Proposed Project is considered the Environmentally Superior Alternative.

Chapter 5
Other Environmental Considerations

This chapter evaluates other environmental considerations, including effects not found to be significant, based on analysis contained in the Initial Study (see Appendix A of this environmental impact report [EIR]), and therefore were subsequently omitted from analysis in the Draft EIR. It also addresses significant irreversible environmental changes that would be caused by the Proposed Project should it be implemented, including the use and consumption of nonrenewable resources or long-term commitments of these resources. The Proposed Project's potential for growth inducement is also addressed in this section.

5.1 Effects Found Not to Be Significant

Section 15128 of the California Environmental Quality Act (CEQA) Guidelines states:

> An EIR shall contain a statement briefly indicating the reasons that various possible significant effects of the project were determined not to be significant and were therefore not discussed in detail in the EIR. Such a statement may be contained in an attached copy of an Initial Study.

In accordance with the requirements of CEQA, the City of Los Angeles (City) prepared an Initial Study, dated November 12, 2015, that identified the topics to be analyzed in the EIR. The Initial Study is contained in Appendix A of this Draft EIR.

Because the analysis contained in the Initial Study determined that the Proposed Project would result in less than significant or no impacts related to the following environmental resource areas, they were eliminated from further analysis:

- Agriculture and Forestry Resources
- Hazards and Hazardous Materials
- Mineral Resources
- Population and Housing
- Public Services
- Recreation

In addition, the analysis contained in the Initial Study also determined that some thresholds of significance for environmental resources addressed in this Draft EIR could be eliminated. These include the following:

- Aesthetics
- Cultural Resources
- Geology and Soils
- Hydrology and Water Quality
- Land Use and Planning

- Noise
- Transportation/Traffic
- Utilities and Service Systems

As noted in the Initial Study, the thresholds of significance eliminated for further analysis for each of these environmental resources are noted by the statement "This issue is not proposed for further analysis in the EIR." The supporting analysis, findings, and conclusions in support of this determination are provided for each of these.

After analysis of the remaining thresholds in the Draft EIR, impacts related to the following issues were determined to be less than significant or less than significant with the implementation of mitigation measures:

- Aesthetics
- Air Quality
- Biological Resources
- Cultural Resources
- Geology and Soils
- Greenhouse Gas Emissions
- Hydrology and Water Quality (except operation related to tsunami and sea level rise)
- Land Use and Planning (except for secondary impacts on surrounding land uses related to construction noise and vibration)
- Noise and Vibration (operation only)
- Transportation/Traffic
- Energy (except cumulative)

5.2 Significant Irreversible Environmental Changes that Would Be Caused by the Proposed Project Should It Be Implemented

Section 15126.2(c) of the State CEQA Guidelines indicates that uses of nonrenewable resources during the initial and continued phases of the project may be irreversible because a large commitment of such resources makes removal or nonuse thereafter unlikely. Primary impacts and, particularly, secondary impacts (such as a highway improvement that provides access to a previously inaccessible area) generally commit future generations to similar uses. Also, irreversible damage can result from environmental accidents associated with the project. Irretrievable commitments of resources should be evaluated to ensure that such current consumption is justified.

Implementation of the Proposed Project would commit nonrenewable (e.g., petroleum) or slowly renewable (e.g., timber) resources during project construction and operation. In order to construct the Proposed Project, machinery, equipment, materials (e.g., lumber, sand, gravel) and workers would be required, representing an irreversibly commitment of some of these resources. Similarly,

during operation, some of these resources (e.g., energy, electricity) would again be needed, representing a long-term commitment and permanent investment. The consumption and use of some of these resources would limit their availability for future generations. In addition, construction of the Proposed Project would also irreversibly change existing views to and from the Grand Canal and Ballona Lagoon for both visitors and residents. However, assuming that these commitments would occur in accordance with the adopted goals, policies, and implementation measures of the City of Los Angeles General Plan, Venice Local Coastal Program, Venice Community Plan, and Venice Local Coastal Specific Plan, as a matter of public policy, such commitments would be acceptable. The Proposed Project would also provide important redundancy and safety and ensure that the existing and future wastewater management needs of the Venice Pumping Plant (VPP) and surrounding service area are met. Therefore, the significant irreversible changes have been deemed acceptable in light of the Proposed Project's overall benefits.

5.3 Growth-Inducing Impacts

Section 15126.2(d) of the State CEQA Guidelines indicates the following relative to growth-inducement:

> Discuss the way in which a proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

A proposed project can result in both direct and indirect growth-inducing impacts. Typically, the development of new housing would result in direct growth-inducement, while the development of new employment opportunities (both short- and long-term) would result in indirect growth-inducement. The removal of an obstacle to growth, such as construction of a necessary public service of infrastructure can also result in indirect growth-inducement. If not considered in local land use or growth management plans, such projects can result in potentially significant and adverse impacts.

As stated in Chapter 2, *Project Description*, the overall objective of the Proposed Project is to reduce the risk of sewage spills by providing redundancy and reliability for the existing VPP wastewater collection system. The Proposed Project would also allow the system to handle future risks related to climate change, including increased storm intensities, which have the potential to result in flows that would be beyond the capacity of the existing VPP. In addition, the Proposed Project is not intended to facilitate growth but instead address existing deficiencies in the system that have been identified and planned for through the City of Los Angeles' normal infrastructure assessment practices.

5.3.1 Direct Population-Generating Uses

The Proposed Project does not include the development of new housing or other population-generating uses that would directly induce population growth or attract a substantial number or workers, nor would it tax existing community service facilities, thereby requiring the construction of

new facilities, which could cause significant environmental effects. Population-generating uses are not proposed. Furthermore, the Proposed Project is considered infill and is located in a highly urbanized area that experienced significant development over the past century, and the service area is primarily built out. Therefore, the Proposed Project would not directly induce new residential development or result in population growth in the service area. Impacts would be **less than significant**, and no mitigation is required.

5.3.2 Growth Accommodation

The population of the area served by the VPP and the Proposed Project has been growing and is projected to keep growing regardless of whether the Proposed Project is implemented. Furthermore, the Proposed Project would meet the current and future need for redundancy, pumping capacity, and reliability to prevent sewage spills and address future risks related to climate change. It would not, however, increase wastewater treatment plant capacity but instead increase wastewater transmission and distribution capacity during storm events and other peak-flow situations. Therefore, the Proposed Project is not growth inducing but, rather, growth accommodating. Impacts would be **less than significant**, and no mitigation is required.

5.3.3 Expansion of Public Services or Utilities

Because the Proposed Project involves creating redundancy and reliability for the collection system, as well as additional capacity to accommodate future risks related to climate change, it inherently involves the expansion of a public facility. However, the improvements would be growth accommodating rather than growth inducing, as described above. The Proposed Project would be designed to ensure that extreme wet-weather events (e.g., El Niño) are accommodated by the VPP and keep pace with flow increases, as predicted by anticipated population increases in the service area. Therefore, it would not create excess wastewater capacity that could stimulate population growth. Although the Proposed Project would involve expansion of a public facility, it would not induce population growth but, rather, accommodate growth that would occur independent of implementation and meet the existing need for redundancy, reliability, and additional capacity. Impacts would be **less than significant**, and no mitigation is required.

NOTICE OF PREPARATION

To: Responsible Agencies, Trustee Agencies, Stakeholders, and Interested Parties

From: City of Los Angeles
Department of Public Works, Bureau of Engineering
Environmental Management Group
1149 S. Broadway, 6th Floor
Los Angeles, CA 90015-2213

Subject: Notice of Preparation of a Draft Environmental Impact Report for the Proposed Venice Auxiliary Pumping Plant Project

Summary: The City of Los Angeles Bureau of Engineering (LABOE) is beginning the environmental review process for the proposed Venice Auxiliary Pumping Plant (VAPP) Project, which would be located adjacent to the existing Venice Pumping Plant at 140 Hurricane Street. LABOE welcomes comments and/or concerns on the content of the environmental information presented and invites you to attend a public meeting in your neighborhood to learn more about the proposed Project and participate in the environmental review process.

The City of Los Angeles (City), Department of Public Works, Bureau of Engineering (BOE), as the CEQA Lead Agency, has prepared a Notice of Preparation (NOP) of a Draft Environmental Impact Report (EIR) for the proposed Venice Auxiliary Pumping Plant (VAPP) Project. BOE has prepared, as part of the NOP, an Initial Study/Environmental Checklist in accordance with current City of Los Angeles Guidelines for Implementation of the California Environmental Quality Act (CEQA) of 1970, Article I and Section 15082 of CEQA Guidelines. The City is requesting input from responsible agencies, trustee agencies, stakeholders, and other interested parties on the scope and content of the environmental information relevant to the statutory responsibilities of agencies and to the concerns of other interested stakeholders. Using the information obtained through the scoping period and the Initial Study, the City will prepare an EIR to analyze the environmental impacts of the proposed Project and alternatives.

Project Location

The proposed Venice Auxiliary Pumping Plant Project (proposed Project) would be located on two existing vacant lots at the northeast corner of Hurricane Street and Canal Court across and immediately north of the existing Venice Pumping Plant in the community of Venice, in the City of Los Angeles, Los Angeles County. Combined, these parcels are approximately 90-feet in length and 70-feet in width (approximately 6,300 square feet). See attached Figure 1, Project Vicinity Map and Figure 2, Project Location Map.

Proposed Project

The proposed Project would include the construction of an auxiliary pumping facility that would provide additional reliability and supplement capacity to the existing Venice Pumping Plant (VPP), located at 140 Hurricane Street in the City of Los Angeles (City) community of Venice. The proposed facility would be sized to supplement the pumping capacity of the VPP, Pump Station No. 646, for a combined ultimate peak flow capacity of 87 million gallons per day (mgd), reflecting wet weather flows of a 10-year storm event. Major project components of the proposed project would include:

- One electrical building approximately 30-feet in height
- Three pumps constructed below ground level
- Utility connections, transformers and generators
- A 17-feet x 17-feet submerged diversion structure, the top of which will be below the lowest elevation of the Grand Canal
- A 66-inch sewer line to connect VAPP to the new diversion structure
- Vacation of a segment of Hurricane Street east of Canal Court to the Esplanade (pedestrian walkway) along the Grand Canal
- Landscaping and benches, green open space and public viewing areas
- Fencing with blinds and vegetation for screening

Potential Environmental Effects

Potential environmental effects associated with the proposed project include the following, which are included in the scope of the Initial Study and will be discussed in detail in the Draft EIR:

- Aesthetics
- Air Quality
- Biological Resources
- Cultural Resources
- Geology/ Soils
- Greenhouse Gas Emissions
- Hydrology/ Water Quality
- Land Use/Planning
- Noise
- Transportation/Traffic
- Utilities/Service Systems

Initial Study

An Initial Study is a preliminary analysis conducted by the CEQA Lead Agency (BOE) to determine whether there is substantial evidence that a project may have a significant effect on the environment. A copy of the Initial Study is available online at:
http://eng.lacity.org/techdocs/emg/venice_aux_pumping_plant.htm .

In addition, hard copies are available for review at the following locations:

- Venice-Abbot Kinney Memorial Library, 501 South Venice Boulevard, Venice, CA 90291
- W Lloyd Taber-Marina del Rey Library, 4533 Admiralty Way, Marina del Rey, CA 90292
- Playa Vista Branch Library, 6400 Playa Vista Drive, Los Angeles, CA 90094

Scoping Meetings

Public scoping meetings will be held to obtain input on the scope and contents of the EIR:

- December 3, 2015, 6:00PM Venice Foursquare Church, 1400 Riviera Avenue, Venice, CA 90291
- December 8, 2015, 6:00PM Abbot Kinney Memorial Library, 501 South Venice Boulevard, Venice, CA 90291

Comments

Please submit your comments, concerns and any other information that will be helpful in preparing an informative EIR by Friday, **December 18, 2015**. **Comments may be submitted by email to: jan.green.rebstock@lacity.org** (please include VAPP Project in the subject line). Please include the name, telephone number, mailing address, and e-mail address of a person to contact if we have any questions regarding your comment.

Comments may also be submitted by mail to:

Dr. Jan Green Rebstock
City of Los Angeles
Public Works, -Bureau of Engineering
Environmental Management Group
1149 S. Broadway, 6th Floor, Mail Stop 939
Los Angeles, CA 90015-2213

If you have any questions about the environmental review process for the proposed VAPP Project, please contact Dr. Jan Green Rebstock at (213) 485-5671.

Air Quality Emissions and Greenhouse Gas Calculations

National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) Attainment Status for South Coast Air Basin

CRITERIA POLLUTANT	STANDARD	AVERAGING TIME	DESIGNATION [a]	ATTAINMENT DATE [b]
1-Hour Ozone	NAAQS	1979 1-Hour (0.12 ppm)	Nonattainment (Extreme)	2/6/2023 Originally 11/15/2010 (not attained)[c]
	CAAQS	1-Hour (0.09 ppm)	Nonattainment	N/A
8-Hour Ozone[d]	NAAQS	1997 8-Hour (0.08 ppm)	Nonattainment (Extreme)	6/15/2024
	NAAQS	2008 8-Hour (0.075 ppm)	Nonattainment (Extreme)	7/20/2032
	NAAQS	2015 8-Hour (0.070 ppm)	Designations Pending	~2037
	CAAQS	8-Hour (0.070 ppm)	Nonattainment	Beyond 2032
CO	NAAQS	1-Hour (35 ppm) 8-Hour (9 ppm)	Attainment (Maintenance)	6/11/2007 (attained)
	CAAQS	1-Hour (20 ppm) 8-Hour (9 ppm)	Attainment	6/11/2007 (attained)
NO_2[e]	NAAQS	1-Hour (0.10 ppm)	Unclassifiable/Attainment	N/A (attained)
	NAAQS	Annual (0.053 ppm)	Attainment (Maintenance)	9/22/1998 (attained)
	CAAQS	1-Hour (0.18 ppm) Annual (0.030 ppm)	Attainment	---
SO_2[f]	NAAQS	1-Hour (75 ppb)	Designations Pending (expect Uncl./Attainment)	N/A (attained)
	NAAQS	24-Hour (0.14 ppm) Annual (0.03 ppm)	Unclassifiable/Attainment	3/19/1979 (attained)
PM10	NAAQS	1987 24-hour (150 µg/m^3)	Attainment (Maintenance)[g]	7/26/2013 (attained)
	CAAQS	24-hour (50 µg/m^3) Annual (20 µg/m^3)	Nonattainment	N/A
PM2.5 [h]	NAAQS	2006 24-Hour (35 µg/m^3)	Nonattainment (Serious)	12/31/2019
	NAAQS	1997 Annual (15.0 µg/m^3)	Nonattainment	4/5/2015
	NAAQS	2012 Annual (12.0 µg/m^3)	Nonattainment (Serious)	12/31/2025
	CAAQS	Annual (12.0 µg/m^3)	Nonattainment	N/A

National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) Attainment Status for South Coast Air Basin

CRITERIA POLLUTANT	STANDARD	AVERAGING TIME	DESIGNATION [a)]	ATTAINMENT DATE [b)]
Lead	NAAQS	3-Months Rolling (0.15 µg/m^3)	Nonattainment (Partial)[i)]	12/31/2015
Hydrogen Sulfide (H_2S)	CAAQS	1-Hour (0.03 ppm/42 µg/m^3)	Attainment	---
Sulfates	CAAQS	24-Hour (25 µg/m^3)	Attainment	---
Vinyl Chloride	CAAQS	24-Hour (0.01 ppm/26 µg/m3)	Attainment	---

a) U.S. EPA often only declares Nonattainment areas; everywhere else is listed as Unclassifiable/Attainment or Unclassifiable

b) A design value below the NAAQS for data through the full year or smog season prior to the attainment date is typically required for attainment demonstration

c) 1-hour O_3 standard (0.12 ppm) was revoked, effective June 15, 2005 ; however, the Basin has not attained this standard based on 2008-2010 data and is still subject to anti-backsliding requirements

d) 1997 8-hour O_3 standard (0.08 ppm) was reduced (0.075 ppm), effective May 27, 2008; the revoked 1997 O_3 standard is still subject to anti-backsliding requirements

e) New NO_2 1-hour standard, effective August 2, 2010; attainment designations January 20, 2012; annual NO_2 standard retained

f) The 1971 annual and 24-hour SO_2 standards were revoked, effective August 23, 2010; however, these 1971 standards will remain in effect until one year after U.S. EPA promulgates area designations for the 2010 SO_2 1-hour standard. Area designations are still pending, with Basin expected to be designated Unclassifiable /Attainment.

g) Annual PM10 standard was revoked, effective December 18, 2006; 24-hour PM10 NAAQS deadline was 12/31/2006; SCAQMD request for attainment redesignation and PM10 maintenance plan was approved by U.S. EPA on June 26, 2013, effective July 26, 2013.

h) Attainment deadline for the 2006 24-Hour PM2.5 NAAQS (designation effective December 14, 2009) is December 31, 2019 (end of the 10th calendar year after effective date of designations for Serious nonattainment areas). Annual PM2.5 standard was revised on January 15, 2013, effective March 18, 2013, from 15 to 12 µg/m3. Designations effective April 15, 2015, so Serious area attainment deadline is December 31, 2025.

i) Partial Nonattainment designation – Los Angeles County portion of Basin only for near-source monitors. Expect to remain in attainment based on current monitoring data.

Notes:

Hourly nitrogen dioxide measurements and related statistics are available at West Los Angeles-VA Hospital between 1984 and 2014. Some years in this range may not be represented.

All concentrations expressed in parts per billion.

An exceedance of a standard is not necessarily related to a violation of the standard.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

Year Coverage:		96		85		100

Notes:

Daily PM10 averages and related statistics are available at Los Angeles-Westchester Parkway between 2004 and 2014. Some years in this range may not be represented.
All averages expressed in micrograms per cubic meter.
The national annual average PM10 standard was revoked in December 2006 and is no longer in effect. Statistics related to the revoked standard are shown in *italics* or *italics* .
An exceedance of a standard is not necessarily related to a violation of the standard.
All values listed above represent midnight-to-midnight 24-hour averages and may be related to an exceptional event.
State and national statistics may differ for the following reasons:
State statistics are based on California approved samplers, whereas national statistics are based on samplers using federal reference or equivalent methods. State and

national statistics may therefore be based on different samplers.

State statistics for 1998 and later are based on local conditions (except for sites in the South Coast Air Basin, where State statistics for 2002 and later are based on local conditions). National statistics are based on standard conditions.

State criteria for ensuring that data are sufficiently complete for calculating valid annual averages are more stringent than the national criteria.

Measurements are usually collected every six days. Measured days counts the days that a measurement was greater than the level of the standard; Estimated days mathematically estimates how many days concentrations would have been greater than the level of the standard had each day been monitored.

3-Year statistics represent the listed year and the 2 years before the listed year.

Year Coverage indicates the extent to which available monitoring data represent the time of the year when concentrations are expected to be highest. 0 means that data represent none of the high period; 100 means that data represent the entire high period. A high Year Coverage does not mean that there was sufficient data for annual statistics to be considered valid.

* means there was insufficient data available to determine the value.

Venice Auxiliary Pumping Plant

Los Angeles-South Coast County, Summer

1.0 Project Characteristics

1.1 Land Usage

Land Uses	Size	Metric	Lot Acreage	Floor Surface Area	Population
General Light Industry	10.00	1000sqft	0.23	10,000.00	0
City Park	0.03	Acre	0.03	1,306.80	0

1.2 Other Project Characteristics

Urbanization	Urban	**Wind Speed (m/s)**	2.2	**Precipitation Freq (Days)**	33
Climate Zone	11			**Operational Year**	2021
Utility Company	Los Angeles Department of Water & Power				
CO2 Intensity (lb/MWhr)	1135	**CH4 Intensity (lb/MWhr)**	0.029	**N2O Intensity (lb/MWhr)**	0.006

1.3 User Entered Comments & Non-Default Data

Project Characteristics - LADWP CO2 intensity factor based on 2013 data from https://data.lacity.org/A-Livable-and-Sustainable-City/LADWP-CO2-Generation/e5ni-eqan. Construction shown to start the year after construction is complete (2021).

Land Use - Site is approximately 10,000 square feet and the pocket park would be approximately 1,000 square feet.

Construction Phase - Schedule based on information provided by the project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - CalEEMod defaults

Off-road Equipment - CalEEMod defaults

Grading - 10,000 cy would be excavated, 2,300 of which would be stockpiled at Laydown Area 1 (adjacent to the site) and 7,700 cy would be stockpiled at Laydown Area 3 (Culver City). All 2,300 cy at Laydown Area 1 would be reused at the project site and half of the Laydown Area 3 materials would be returned to the site. The remaining 3,850 would taken to a landfill.

Trips and VMT - Due to the small roadways near the project site, trucks with a 7-cy capacity were assumed. Laydown Area 1 is adjacent to the site (0.1 trip distance assumed), Laydown Area 3 is 7 miles from the project site, landfill site assumed to be 20 miles from Laydown Area 3. The weighted average trip distance is 8.93 miles. Worker trips based on two trips per day for the number of workers provided by the project engineer

On-road Fugitive Dust - CalEEMod defaults

Architectural Coating - Based on dimensions from Preliminary Design Report.

Vehicle Trips - Pocket park is assumed to generate no trips, as users would be neighborhood residents. The pumping plant would be operated by two employees per 8-hour shift, 24 hours per day, 7 days per week.

Energy Use - The new pumps would be used to achieve the same levels of of wastewater flow as at present; new energy consumption would occur as result of the VAPP operational center, which would consume 569,400 kWh. Energy consumption woudl be 56.94 per square feet of the facility. CalEEMod defaults used for all other energy intensities.

Water And Wastewater - Potable water would be used for washdown and lavatory purposes. Defaults used.

Solid Waste - CalEEMod defaults

Construction Off-road Equipment Mitigation - Rule 403 compliance

Area Coating - Based on dimensions from Preliminary Design Report.

7.0 Water Detail

7.1 Mitigation Measures Water

8.0 Waste Detail

8.1 Mitigation Measures Waste

9.0 Operational Offroad

Equipment Type	Number	Hours/Day	Days/Year	Horse Power	Load Factor	Fuel Type

10.0 Vegetation

Venice Auxiliary Pumping Plant - Mitigated with Tier 3 Equipment

Los Angeles-South Coast County, Summer

1.0 Project Characteristics

1.1 Land Usage

Land Uses	Size	Metric	Lot Acreage	Floor Surface Area	Population
General Light Industry	10.00	1000sqft	0.23	10,000.00	0
City Park	0.03	Acre	0.03	1,306.80	0

1.2 Other Project Characteristics

Urbanization	Urban	**Wind Speed (m/s)**	2.2	**Precipitation Freq (Days)**	33
Climate Zone	11			**Operational Year**	2021
Utility Company	Los Angeles Department of Water & Power				
CO2 Intensity (lb/MWhr)	1135	**CH4 Intensity (lb/MWhr)**	0.029	**N2O Intensity (lb/MWhr)**	0.006

1.3 User Entered Comments & Non-Default Data

Project Characteristics - LADWP CO2 intensity factor based on 2013 data from https://data.lacity.org/A-Livable-and-Sustainable-City/LADWP-CO2-Generation/e5ni-eqan. Construction shown to start the year after construction is complete (2021).

Land Use - Site is approximately 10,000 square feet and the pocket park would be approximately 1,000 square feet.

Construction Phase - Schedule based on information provided by the project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - CalEEMod defaults

Off-road Equipment - CalEEMod defaults

Grading - 10,000 cy would be excavated, 2,300 of which would be stockpiled at Laydown Area 1 (adjacent to the site) and 7,700 cy would be stockpiled at Laydown Area 3 (Culver City). All 2,300 cy at Laydown Area 1 would be reused at the project site and half of the Laydown Area 3 materials would be returned to the site. The remaining 3,850 would taken to a landfill.

Trips and VMT - Due to the small roadways near the project site, trucks with a 7-cy capacity were assumed. Laydown Area 1 is adjacent to the site (0.1 trip distance assumed), Laydown Area 3 is 7 miles from the project site, landfill site assumed to be 20 miles from Laydown Area 3. The weighted average trip distance is 8.93 miles. Worker trips based on two trips per day for the number of workers provided by the project engineer

On-road Fugitive Dust - CalEEMod defaults

Architectural Coating - Based on dimensions from Preliminary Design Report.

Vehicle Trips - Pocket park is assumed to generate no trips, as users would be neighborhood residents. The pumping plant would be operated by two employees per 8-hour shift, 24 hours per day, 7 days per week.

Energy Use - The new pumps would be used to achieve the same levels of of wastewater flow as at present; new energy consumption would occur as result of the VAPP operational center, which would consume 569,400 kWh. Energy consumption woudl be 56.94 per square feet of the facility. CalEEMod defaults used for all other energy intensities.

Water And Wastewater - Potable water would be used for washdown and lavatory purposes. Defaults used.

Solid Waste - CalEEMod defaults

Construction Off-road Equipment Mitigation - Rule 403 compliance and Tier 3 equipment

Area Coating - Based on dimensions from Preliminary Design Report.

8.0 Waste Detail

8.1 Mitigation Measures Waste

9.0 Operational Offroad

Equipment Type	Number	Hours/Day	Days/Year	Horse Power	Load Factor	Fuel Type

10.0 Vegetation

Venice Auxiliary Pumping Plant

Los Angeles-South Coast County, Annual

1.0 Project Characteristics

1.1 Land Usage

Land Uses	Size	Metric	Lot Acreage	Floor Surface Area	Population
General Light Industry	10.00	1000sqft	0.23	10,000.00	0
City Park	0.03	Acre	0.03	1,306.80	0

1.2 Other Project Characteristics

Urbanization	Urban	**Wind Speed (m/s)**	2.2	**Precipitation Freq (Days)**	33
Climate Zone	11			**Operational Year**	2021
Utility Company	Los Angeles Department of Water & Power				
CO2 Intensity (lb/MWhr)	1135	**CH4 Intensity (lb/MWhr)**	0.029	**N2O Intensity (lb/MWhr)**	0.006

1.3 User Entered Comments & Non-Default Data

Project Characteristics - LADWP CO2 intensity factor based on 2013 data from https://data.lacity.org/A-Livable-and-Sustainable-City/LADWP-CO2-Generation/e5ni-eqan. Construction shown to start the year after construction is complete (2021).

Land Use - Site is approximately 10,000 square feet and the pocket park would be approximately 1,000 square feet.

Construction Phase - Schedule based on information provided by the project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - CalEEMod defaults

Off-road Equipment - CalEEMod defaults

Grading - 10,000 cy would be excavated, 2,300 of which would be stockpiled at Laydown Area 1 (adjacent to the site) and 7,700 cy would be stockpiled at Laydown Area 3 (Culver City). All 2,300 cy at Laydown Area 1 would be reused at the project site and half of the Laydown Area 3 materials would be returned to the site. The remaining 3,850 would taken to a landfill.

Trips and VMT - Due to the small roadways near the project site, trucks with a 7-cy capacity were assumed. Laydown Area 1 is adjacent to the site (0.1 trip distance assumed), Laydown Area 3 is 7 miles from the project site, landfill site assumed to be 20 miles from Laydown Area 3. The weighted average trip distance is 8.93 miles. Worker trips based on two trips per day for the number of workers provided by the project engineer

On-road Fugitive Dust - CalEEMod defaults

Architectural Coating - Based on dimensions from Preliminary Design Report.

Vehicle Trips - Pocket park is assumed to generate no trips, as users would be neighborhood residents. The pumping plant would be operated by two employees per 8-hour shift, 24 hours per day, 7 days per week.

Energy Use - The new pumps would be used to achieve the same levels of of wastewater flow as at present; new energy consumption would occur as result of the VAPP operational center, which would consume 569,400 kWh. Energy consumption woudl be 56.94 per square feet of the facility. CalEEMod defaults used for all other energy intensities.

Water And Wastewater - Potable water would be used for washdown and lavatory purposes. Defaults used.

Solid Waste - CalEEMod defaults

Construction Off-road Equipment Mitigation - Rule 403 compliance

Area Coating - Based on dimensions from Preliminary Design Report.

9.0 Operational Offroad

Equipment Type	Number	Hours/Day	Days/Year	Horse Power	Load Factor	Fuel Type

10.0 Vegetation

Venice Auxiliary Pumping Plant - Mitigated with Tier 3 Equipment

Los Angeles-South Coast County, Annual

1.0 Project Characteristics

1.1 Land Usage

Land Uses	Size	Metric	Lot Acreage	Floor Surface Area	Population
General Light Industry	10.00	1000sqft	0.23	10,000.00	0
City Park	0.03	Acre	0.03	1,306.80	0

1.2 Other Project Characteristics

Urbanization	Urban	**Wind Speed (m/s)**	2.2	**Precipitation Freq (Days)**	33
Climate Zone	11			**Operational Year**	2021
Utility Company	Los Angeles Department of Water & Power				
CO2 Intensity (lb/MWhr)	1135	**CH4 Intensity (lb/MWhr)**	0.029	**N2O Intensity (lb/MWhr)**	0.006

1.3 User Entered Comments & Non-Default Data

Project Characteristics - LADWP CO2 intensity factor based on 2013 data from https://data.lacity.org/A-Livable-and-Sustainable-City/LADWP-CO2-Generation/e5ni-eqan. Construction shown to start the year after construction is complete (2021).

Land Use - Site is approximately 10,000 square feet and the pocket park would be approximately 1,000 square feet.

Construction Phase - Schedule based on information provided by the project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - Equipment list provided by project engineer.

Off-road Equipment - CalEEMod defaults

Off-road Equipment - CalEEMod defaults

Grading - 10,000 cy would be excavated, 2,300 of which would be stockpiled at Laydown Area 1 (adjacent to the site) and 7,700 cy would be stockpiled at Laydown Area 3 (Culver City). All 2,300 cy at Laydown Area 1 would be reused at the project site and half of the Laydown Area 3 materials would be returned to the site. The remaining 3,850 would taken to a landfill.

Trips and VMT - Due to the small roadways near the project site, trucks with a 7-cy capacity were assumed. Laydown Area 1 is adjacent to the site (0.1 trip distance assumed), Laydown Area 3 is 7 miles from the project site, landfill site assumed to be 20 miles from Laydown Area 3. The weighted average trip distance is 8.93 miles. Worker trips based on two trips per day for the number of workers provided by the project engineer

On-road Fugitive Dust - CalEEMod defaults

Architectural Coating - Based on dimensions from Preliminary Design Report.

Vehicle Trips - Pocket park is assumed to generate no trips, as users would be neighborhood residents. The pumping plant would be operated by two employees per 8-hour shift, 24 hours per day, 7 days per week.

Energy Use - The new pumps would be used to achieve the same levels of of wastewater flow as at present; new energy consumption would occur as result of the VAPP operational center, which would consume 569,400 kWh. Energy consumption woudl be 56.94 per square feet of the facility. CalEEMod defaults used for all other energy intensities.

Water And Wastewater - Potable water would be used for washdown and lavatory purposes. Defaults used.

Solid Waste - CalEEMod defaults

Construction Off-road Equipment Mitigation - Rule 403 compliance and Tier 3 equipment

Area Coating - Based on dimensions from Preliminary Design Report.

Chapter 1
Introduction

This report contains the results of a biological resources and habitat assessment conducted for the Venice Auxiliary Pumping Plant Project (VAPP or proposed project) located in the City of Los Angeles, Los Angeles County, California.

1.1 Project Location

The proposed project is located at the northeast corner of Hurricane Street and Canal Court across and immediately north of the existing Venice Pumping Plant (Figure 1). The project would be located on two three existing vacant lots (Assessor Parcel Numbers [APN]: 4225-008-904 and 42250089044225-010-016), which are owned by the City of Los Angeles, two of which would serve as laydown areas. Laydown Area 1 would be used for soil stockpile and construction materials and equipment and then permanently converted to parking and open space once the proposed project is operational. Laydown Area 2, located on the east side of the Grand Canal would be used for temporary storage of construction material and equipment, and two laydown areas, as well as within the Grand Canal. The site is mapped in Township 2 South, Range 15 West, Section 21 U.S. Geological Survey (USGS) 7.5-minute "Venice" quadrangle map (USGS 1964) (Figure 2).

1.2 Project Description

The project would include the construction of an auxiliary pumping facility that would provide additional reliability and supplement capacity to the existing Venice Pumping Plant (VPP). The project would be sized to supplement the pumping capacity of the VPP (Pump Station No. 646), for a combined ultimate peak flow capacity of 87 million gallons per day (mgd), reflecting wet weather flows of a 10-year storm event. Major project components of the VAPP would include: one electrical building approximately 3532-feet in height, three pumps constructed below ground level, utility connections, transformers and generators, 17-feet by 17-feet submerged diversion structure, the top of which will be below the channel bed, or the lowest elevation of the Grand Canal, and a 66-inch sewer to connect VAPP to the new diversion structure. A portion of Hurricane Street between and Canal Court and Esplanade would be temporarily closed off during construction and then reopened, with Hurricane Street from Canal Court to Esplanade closed to the public once the facility is operational. Shoring would be installed around the project site, and then excavation would occur to a depth of approximately 25 feet. The proposed project would require the excavation of approximately 10,000 cubic yards of soil of which approximately 2,300 cubic yards would be stockpiled at Laydown Area 1. The remaining 7,700 cubic yards of soil would be exported off-site and stockpiled at Laydown Area 3 in Culver Cityexported off-site and disposed of in an approved area landfill. Laydown Area 2 (across Grand Canal), given the slope and access constraints, may be used only as needed for equipment and materials storage. Water pumped from the site would be disposed of in a manner consistent with Regional Water Quality Control Board (RWQCB) regulations. Construction of the underground facilities associated with the VAPP, including the three new pumps, the wet well, valve vault, meter vault and piping, would occur. These facilities would be

Figure 2
USGS Topographic Map
Venice Auxiliary Pumping Plant Project

constructed at a maximum depth of approximately 25 feet below ground. Within the Grand Canal, a diversion structure approximately 23-feet by 95-feet would be excavated to a depth of approximately 18 feet below ground and then sealed. Excavated materials would be hauled from the site and stockpiled at either Laydown Area 1 or Laydown Area 3 or transported to an approved area landfill; upon completing of installation and sealing, The Grand Canal would be backfilled using the stockpiled excavated material and the coffer dam removed.Excavated materials would be hauled from the site and disposed of at an appropriate location. Water flowing in the Grand Canal would be diverted around a cofferdam structure by the presence of the dam itself. The diversion structure would then be constructed around the in-service Coastal Interceptor Sewer (CIS) pipe. Construction of the cofferdam, placement of the diversion structure, and backfill and soil compaction within the Grand Canal would last approximately three months. The CIS pipe would be cut so that the modular insert could be installed. The pipes would then be connected and a seal would be inserted into the shell. Backfill and soil compaction would be completed, and the Grand Canal channel bottom would be restored to its original elevation. Finally, the diversion structure will be sealed, removing all shoring steel, and allowing flows to resume to pre-construction conditions within the Grand Canal. The Esplanade would be re-opened to pedestrian access on the west side of the Grand Canal. Surface improvements at the site will occur, consisting of constructing an approximately 3532-foot high electrical building and installing two new 480-Volt City of Los Angeles Department of Water and Power transformers.

Chapter 2
Methods

2.1 Terminology

Within this report, the term "project" refers to the proposed construction footprint encompassing the proposed construction limits and lay down areas. The term "study area" refers to the project site plus an additional 500-foot buffer area surrounding the project site. Special-status species referred to in this report include those wildlife and plants listed as threatened or endangered under federal or state endangered species acts (CDFW 2015a); plant species designated by the California Native Plant Society (CNPS) with a California Rare Plant Rank (CRPR) or other plants of local concern (CNPS 2015); and wildlife that is designated as a California Species of Special Concern, as defined by the California Department of Fish and Wildlife (CDFW) (CDFW 2015a).

2.2 Database Search and Literature Review

A literature review was conducted to evaluate the environmental setting of the study area prior to the habitat assessment and identify special-status species or potentially suitable habitat for special-status species. The literature review included a review of the U.S. Fish and Wildlife Service (USFWS) mapping of designated critical habitat and generation of a species list (USFWS 2015, 2016). In addition, the National Marine Fisheries Service Essential Fish Habitat was reviewed to determine if the study area contains designated Essential Fish Habitat (NOAA 2015). The California Natural Diversity Database (CNDDB) (CDFW 2015b) and the CNPS Inventory of Rare and Endangered Plants (CNPS 2015) were reviewed for the Venice (USGS 1964) and surrounding USGS 7.5-minute quadrangles.

Previous reports reviewed include The Ballona Wetlands Ecological Reserve Baseline Assessment Program 2010-2011 Final Report (Johnson 2012) and previous Los Angeles Bureau of Engineering studies including biological resource surveys for the ESR-Hurricane Maintenance Hole Replacement, Grand Canal West Bank, Venice Tide Gates, and Venice Pumping Plant Sluice Gate Replacement (Jones 2016).

2.3 Biological Resources

ICF International (ICF) biologists Shannon Crossen and Marissa Maggio, conducted a habitat assessment for special-status biological resources within the study area on August 20th, 2015. The habitat assessment was conducted between 0930 and 1330, and temperatures ranged from 74˚ to 78˚ Fahrenheit. Winds were calm, and cloud cover was overcast and later becoming clear. Visibility was good.

During the habitat assessment, photos of the study area were taken (see Appendix A). All plant species observed or otherwise detected during the habitat assessment were recorded in a field notebook. Common plant species observed were identified by visual characteristics and morphology in the field. Any unusual and less-familiar plants were identified in the office using taxonomic keys

and guides. Taxonomic nomenclature for plants follows *The Jepson Manual: Vascular Plants of California* (Baldwin et al. 2012). A complete list of all plant species observed during the site visit is found in Appendix B of this document. Appendix B also includes a list of plants observed during previous surveys there were not detected during this habitat assessment (LADPW 2005).

All wildlife species observed or otherwise detected during the habitat assessment were recorded in a field notebook. Wildlife species were detected by sight, calls, tracks, scat, or other sign. Field guides were used to assist with identification of species during surveys and included the *National Geographic Field Guide to the Birds of North America* (National Geographic 2002) for birds, *Western Reptiles and Amphibians* (Stebbins 2003) for reptiles, and *A Field Guide to the Mammals of North America* (Reid 2006) for mammals. A complete list of all wildlife species observed during the site visit is found in Section 3.4 of this document.

2.3.1 Vegetation/Land Use/Land Condition Mapping

Vegetation/land use/land condition within the study area was mapped during the habitat assessment on a satellite aerial image of the site taken from Google Earth (scale: 1 inch = 200 feet) (Google Earth 2015). The Google Earth image was also evaluated to confirm conditions within the extended project footprint within the canal channel, and the associated 500-foot buffer. Community descriptions from the *Preliminary Descriptions of Terrestrial Natural Communities of California.* (Holland 1986) were used to classify the vegetation within the study area where possible.

2.4 Survey Limitations

Plant and animal observations were limited because of the timing of the surveys (mid-August). As such, it is important to note that additional species, beyond those observed in this evaluation, may occur in the study area, but may not have been detected. For example, some species may not have been found because they were not present at the time of day or time of year that the fieldwork was conducted. Some special survey methods may be required to determine the presence or absence of some species (e.g., rare plant surveys during a species blooming season). Therefore, the plants and wildlife species observed and reported herein are not intended to be complete lists of species present within the study area; they include only those species observed during the habitat assessment.

2.5 Regulatory Constraints

Applicable local, state, and federal laws and regulations, as well as court precedents enacted to protect and/or manage biological resources, were evaluated for their relevance and potential to constrain the proposed project. The analysis of constraints provided in this report is based on a combination of direct evaluation of the site, current regulatory information, and professional judgment.

2.5.1 Federal Laws

The federal laws listed below were considered during evaluation of the biological resources in the study area. Note that this is not an exhaustive list of all federal laws that may be applicable to the project.

- *Endangered Species Act of 1973* (including designated critical habitat for listed species)
- *Environmental Quality Improvement Act of 1970*
- *Federal Noxious Weed Act of 1974*
- *Federal Water Pollution Control Act* (Clean Water Act, CWA)
- *Rivers and Harbors Appropriations Act of 1899*
- *Fish and Wildlife Act of 1956*
- *Migratory Bird Treaty Act*
- *National Environmental Policy Act of 1969*

2.5.2 State Laws and Regulations

The state laws and regulations listed below were considered during evaluation of the biological resources in the study area. Note that this is not an exhaustive list of all state laws and regulations that may be considered.

- *California Environmental Quality Act* (CEQA) (Public Resources Code Sections 21000–21177, CEQA Guidelines Sections 15000–15387)
- *California Fish and Game Code* (including codes for the state Endangered Species Act, those similar to the federal Migratory Bird Treaty Act, those for lake or streambed alteration agreements, and those for navigation dredging permits)
- In California, the State Water Resources and nine Regional Water Quality Control Boards regulate activities within state and federal waters under Section 401 of the CWA and the Porter-Cologne Act. Waters of the State under the Porter-Cologne Act are defined as "any surface water or groundwater, including saline waters, within the boundaries of the state" (California Water Code 13050 [e])
- *Coastal Zone Management Act* (Title 16 United States Code 1451–1464)
- *The California Coastal Act* (California Public Resources Code Division 20, Section 30240a) restricts land uses within or adjacent to Environmentally Sensitive Habitat Areas (ESHAs). The *California Coastal Act*, Section 30107.5, defines an ESHA as:
    - …any area in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and could be easily disturbed or degraded by human activities and developments.

2.5.3 Local Regulations

The local regulations listed below were considered during evaluation of the biological resources in the study area. Note that this is not an exhaustive list of all local regulations that may be considered.

- L.A. CEQA Thresholds Guide
- City of Los Angeles General Plan
- Venice Community Plan
- Venice Local Coastal Program

Chapter 3
Existing Conditions

The following discussions address conditions and biological resources observed or potentially present in the study area. Chapter 4 and Appendix C contain specific details regarding habitat assessments conducted for special-status resources.

3.1 Environmental Setting

The project is located within an urban area within the City of Los Angeles community of Venice. The study area is surrounded on the north and west by residential land uses and to the east by the Grand Canal and Ballona Lagoon to the south. Residential land uses are also located immediately east of the Grand Canal. Two parcels associated with the project are currently undeveloped vacant lots surrounded by a chain-link fence. Two other undeveloped lots will function as laydown areas during construction. Elevations within the study area range from approximately 0 feet to approximately 10 feet above mean sea level (MSL).

3.2 Vegetation/Land Use Types

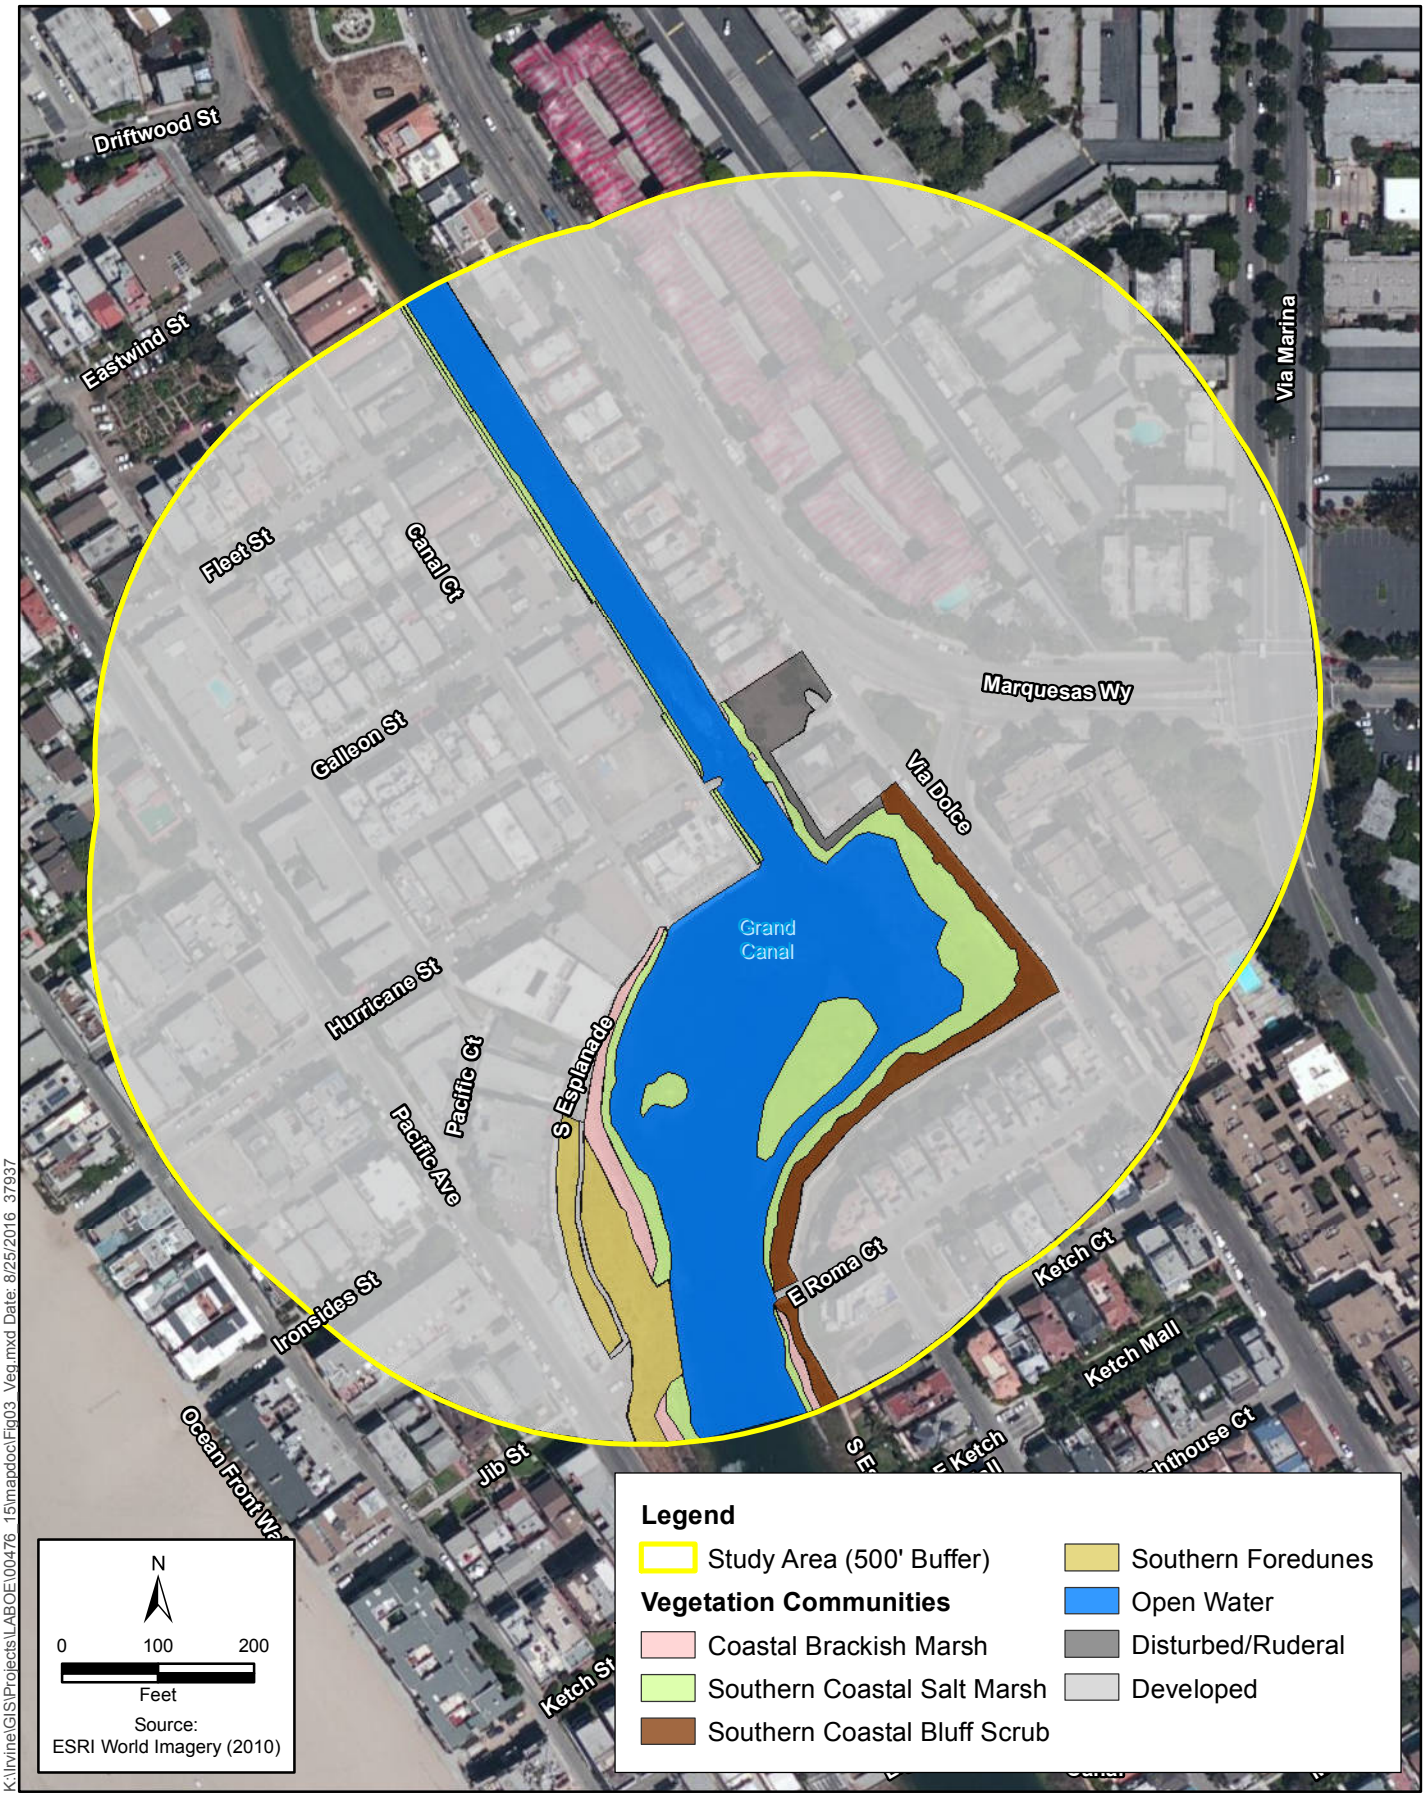
The study area is composed of ornamental vegetation associated with developed and/or disturbed lots surrounding the Grand Canal and Ballona Lagoon, both of which contain native plant communities with varying composition of non-native species. Vegetation types/land uses within the study area are discussed below. Table 1 provides data regarding the vegetation communities, including land use types and acreages for each community mapped within the study area. Figure 3 depicts the location of each vegetation community within the study area.

Table 1. Vegetation Communities/Land Use/Land Condition within the Study Area

Vegetation Community/Land Use/Land Condition	Acres
Developed	24.60
Disturbed/Ruderal	0.18
Open Water	3.13
Southern Coastal Salt Marsh	0.90
Coastal Brackish Marsh	0.16
Southern Foredunes	0.43
Southern Coastal Bluff Scrub	0.35
Total	**29.74**

3.2.1 Developed

Developed lands were mapped in association with the residential structures and surface roads within the study area and include ornamental vegetation typically associated with the developed



K:\Irvine\GIS\Projects\LABOE\00476_15\mapdoc\Fig03_Veg.mxd Date: 8/25/2016 37937

Figure 3
Vegetation Communities
Venice Auxiliary Pumping Plant Project

areas such as Mexican fan palm (*Washingtonis robusta*), acacia (*Acacia* sp.), eucalyptus (*Eucalyptus* sp.), Peruvian pepper tree (*Schinus molle*), iceplant (*Carpobrotus* sp.), and myoporum (*Myoporum* sp.).

3.2.2 Disturbed/Ruderal

This area vegetation type was mapped on the eastern side of the study area associated with a vacant lot surrounded by developed lands to the north, east, and south. The area contains a small footpath leading from the sidewalk adjacent to the Grand Canal to the Via Dolce surface street. This area is dominated by non-native and native annual and perennial species such as iceplant, garland chrysanthemum (*Glebionis coronaria*), telegraphweed (*Heterotheca grandifolia*), cheeseweed (*Malva parviflora*), Bermuda grass (*Cynodon dactylon*), and Australian saltbush (*Atriplex semibaccata*).

3.2.3 Open Water

Open Water consists of the tidal influenced Grand Canal. Grand Canal opens to Marina del Rey approximately 4,000 feet to the south through a flood gate system under Via Marina road. Mudflats occur within the tidally-influenced portions of the BSA and exposed areas of mudflats fluctuate with tide. A small strip of exposed mudflat occurs within the project footprint during low tides within this habitat type.

3.2.4 Southern Coastal Salt Marsh (Holland 52120)

This vegetation type was mapped within the tidal zone of the Grand Canal and Ballona Lagoon. This area is dominated by native wetland species such as pickleweed (*Sarcocornia pacifica*), batis (*Batis maritima*), wooly seablight (*Suaeda taxifolia*[1]), spearscale (*Atriplex prostrata*), and fleshy jaumea (*Jaumea carnosa*). Wooly seablight is a CNPS CRPR List 4.2 species (plants of limited distribution). The upper portions of this area support species such as salt grass (*Distichilis spicata*), five-hooked bassia (*Bassia hyssopifolia*), beach bur (*Ambrosia chamissonis*), and alkali heath (*Frankenia salina*) indicating the start of the wetland-upland interface. Two "islands" were mapped within the Ballona Lagoon that are periodically covered by tidal waters each day.

3.2.5 Coastal Brackish Marsh (Holland 52200) -

This vegetation type was mapped immediately above the tidal zone of the Grand Canal and Ballona Lagoon. This area is dominated by species such as alkali heath, salt grass, five-hooked bassia, woolly seablight, beach bur, alkali heliotrope (*Heliotropium curassavicum*), and deerweed (*Acmispon glaber*). The lower portion of this area transitions to wetland species such as pickleweed, batis, and fleshy jaumea.

3.2.6 Southern Foredunes (Holland 21230)

This area was mapped on the western side of Ballona Lagoon within the southwestern portion of the study area. This area is dominated by upland coastal dune and maritime sage scrub species. Dominant species observed on the western side of the lagoon include beach bur, deerweed, bluff

[1] *Suaeda taxifolia* is designated as a CNPS CRPR 4.2 species.

buckwheat (*Eriogonum parviflora*), red sand verbena (*Abronia maritima*[2]), beach evening primrose (*Camissonia cheiranthifolia*), southwestern spiny rush (*Juncus acutus* ssp. *leopoldii*[3]), telegraphweed (*Heterotheca grandifolia*), and Watson's saltbush (*Atriplex watsonii*).

3.2.7 Southern Coastal Bluff Scrub (Holland 31200)

This area was mapped on the eastern side of Ballona Lagoon. Dominant species observed in this area include southwestern spiny rush, California encelia (*Encelia californica*), California sagebrush (*Artemisia californica*), prickly-pear cactus (*Opuntia littoralis*), and lemonade berry (*Rhus integrifolia*).

3.3 Plants

Most plant species that were observed within the study area are considered common within the study area vicinity. However, three special-status species were determined to be present within the study area: woolly seablite, southwestern spiny rush, and red sand verbena, each of which is CNPS CRPR List 4.2 species. In addition, suitable habitat for other special-status plant species is present within the study area and is discussed in Section 4.1.

Common native plant species observed during the habitat assessment included the following species: lemonade berry (*Rhus integrifolia*), California sagebrush(*Artemisia californica*), California encelia (*Encelia californica*), , telegraphweed (*Heterotheca grandifolia*), alkali heath (*Frankenia salina*), alkali heliotrope(*Heliotropium curassavicum*) , prickly-pear cactus (*Opuntia littoralis*), saltwort , deerweed (*Acmispon glaber*), salt grass (*Distichilis spicata*), gut weed (*Ulva intestinalis*), sea lettuce (*Ulva lactuca*), western ragweed (*Ambrosia psilostachya*), ragweed (*Ambrosia* sp.), coastal goldenbush (*Isocoma menziesii*), beachwort (*Batis maritima*), mouse-ear chickweed (*Cerastium* sp.), Parish's pickleweed (*Arthrocnemum subterminale*), big saltbush (*Atriplex lentiformis*), saltbush (*Atriplex* sp.), Pacific pickleweed (*Salicornia pacifica*), pickleweed (*Salicornia* sp.), salt dodder (*Cuscuta salina*), vetch (*Vicia* sp.), suncup (*Camissonia* sp.), seacliff buckwheat (*Eriogonum parvifolium*), nightshade (*Solanum* sp.), and brittlegrass (*Setaria* sp.).

Common nonnative species observed during the habitat assessment included: Mexican fan palm (*Washingtonis robusta*), acacia (*Acacia* sp.), eucalyptus (*Eucalyptus* sp.), Australian saltbush(*Atriplex semibaccata*), Bermuda grass (*Cynodon dactylon*), flax-leaved horseweed (*Erigeron bonariensis*), five-hooked bassia, cheeseweed, baby sun-rose (*Aptenia cordifolia*), fat-hen (*Atriplex prostrata*), hottentot fig (*Carpobrotus* sp.), Lamb's quarters (*Chenopodium album*), whitestem filaree (*Erodium moschatum*),spotted spurge (*Euphorbia maculate*), crown daisy (*Glebionis coronaria*), grass poly (*Lythrum hyssopifolia*), Ngaio tree (*Myoporum laetum*), Brazilian pepper tree (*Schinus terebinthifolius*), sowthistle (*Sonchus* sp.), and puncturevine (*Tribulus terrestris*).

Appendix B provides a list of all plant species observed on the project site during the habitat assessment, as well as those observed during previous studies (LADPW 2005)

[2] *Abronia maritima* is designated as a CNPS CRPR 4.2 species.

[3] *Juncus acutus* is designated as a CNPS CRPR 4.2 species.

3.4 Wildlife

Wildlife species that were observed within the study area are considered common to the general project vicinity. The majority of species detected were birds. Bird species observed and/or heard during the habitat assessment include mallard (*Anas platyrhynchos*), mourning dove (*Zenaida macroura*), Anna's hummingbird (*Calypte anna*), white-throated swift (*Aeronautes saxatalis*), barn swallow (*Hirundo rustica*), cliff swallow (*Petrochelidon pyrrhonota*), northern rough-winged swallow (*Stelgidopteryx serripennis*), black phoebe (*Sayornis nigricans*), American crow (*Corvus brachyrhynchos*), common raven (*Corvus corax*), European starling (*Sturnus vulgaris*), house finch (*Carpodacus mexicanus*), double-crested cormorant (*Phalacrocorax auritus*), great blue heron (*Ardea herodias*), great egret (*Ardea alba*), osprey (*Pandion haliaetus*), American coot (*Fulica americana*), black-bellied plover (*Pluvialis squatarola*), willet (*Tringa semipalmata*), whimbrel (*Numenius phaeopus*), marbled godwit (*Limosa fedoa*), and belted kingfisher (*Ceryle alcyon*).

Marine invertebrates observed included buckshot barnacles (*Chthalamus* spp.), blue mussel (*Mytilus edulis*), California horn snail (*Cerithidea californica*), California mussel (*Mytilus californianus*), checkered limpet (*Lottia strigatella*), Gould's bubble snail (*Bulla gouldiana*), and Pacific oyster (*Ostrea lurida*). Additional marine invertebrates observed within the Grand Canal include commonly-occurring bivalves, mollusks, and crustaceans (LADPW 2005). Marine vertebrates observed included California corbina (*Menticirrhus undulates*) and topsmelt (*Atherinops affinis*). Appendix B provides a list of all wildlife species observed on the project site during the habitat assessment.

Suitable habitat for several special-status wildlife species is present within the study area and is discussed in Section 4.2.

3.5 Federal and State Jurisdictional Resources

The Grand Canal is a potential jurisdictional waters of the U.S., to Army Corps of Engineers (USACE) and the RWQCB, as well as the California Coastal Commission (CCC). A jurisdictional delineation was prepared for the project, the results of which are presented under separate cover. Please see the jurisdictional delineation report prepared for the proposed project titled *Jurisdictional Delineation Report, Venice Auxiliary Pumping Plant, Community of Venice, Los Angeles County, California,* dated January 2016 (ICF 2016), for a complete analysis of the federal and state jurisdictional resources present at the project site.

The jurisdictional delineation study area is defined as the project footprint plus a 100-foot buffer. Within the study area, two named features that could be subject to the jurisdiction of the USACE, RWQCB, and CCC were delineated: Ballona Lagoon and Grand Canal. These two features are treated as one for the purpose of this document. USACE and RWQCB potential jurisdictional areas within the study area total approximately 0.929-acre of Section 404 non-wetland waters of the U.S. /Section 401 non-wetland waters of the State and 0.075-acre of Section 404 wetland waters of the U.S. and Section 401 wetland waters of the State (Table 2). Additionally, 0.793-acre of potential USACE Section 10 waters of the U.S. was mapped in the study area. Potential CCC jurisdiction within the study area totaled approximately 0.929-acre of one-parameter wetlands.

Table 2. Jurisdictional Delineation Summary (acres)

Study Area Feature	USACE Section 404 Non-Wetland Waters of the U.S./RWQCB Section 401 Non-Wetland Waters of the State	USACE Section 404 Wetland Waters of the U.S./RWQCB Section 401 Wetland Waters of the State	USACE Section 10 Navigable Waters of the U.S.	CCC 1-Parameter Wetlands
Ballona Lagoon and Grand Canal	0.929	0.075	0.793	0.929
Total	**0.929**	**0.075**	**0.793**	**0.929**

Chapter 4
Results of Habitat Assessments

The following discussions address the results of habitat assessments conducted for special-status plant and wildlife species occurring or potentially occurring within the study area, as well as other sensitive biological resources. Appendix C contains specific details regarding the habitat assessments conducted for special-status resources and their potential for occurrence within the study area.

Special-status species are plants and animals that are legally protected under the *California Endangered Species Act* (CESA), the *Federal Endangered Species Act* (FESA), or other regulations, as well as species considered sufficiently rare by the scientific community to qualify for such listing. Special-status species are defined as:

- Species listed or proposed for listing as threatened or endangered under the FESA (Title 50, *Code of Federal Regulations* [CFR], Section 17.12 for listed plants, 50 CFR 17.11 for listed animals, and various notices in the Federal Register [FR] for proposed species);
- Species that are candidates for possible future listing as threatened or endangered under the FESA (CFR 71:53756-53835, September 12, 2006);
- Species that are listed or proposed for listing by the State of California as threatened or endangered under CESA (Title 14, *California Code of Regulations* [CCR], Section 670.5);
- Plants listed as rare under the *California Native Plant Protection Act of 1977* (*California Fish and Game Code*, Section 1900, et seq.);
- Plants considered by CNPS to be "rare, threatened, or endangered in California and elsewhere" (List 1B, 2, and 3. List 4 species were included and evaluated in the impact analysis to determine whether they should be considered special-status species for the purposes of CEQA) (CNPS 2015);
- Species that meet the definition of rare or endangered under CEQA Guidelines, Section 15380;
- Animals fully protected in California (*California Fish and Game Code*, Section 3511 [birds], 4700 [mammals], and 5050 [reptiles and amphibians]); or,
- Animal species of special concern to CDFW.

4.1 Special-Status Plants

Habitat assessments for all special-status plant species evaluated are presented in Appendix C. Of the 47 special-status species evaluated, three species were determined to be present within the study area: woolly seablite, southwestern spiny rush, and red sand verbena, each of which is CNPS CRPR List 4.2 species. These species are discussed in more detail below in Section 4.1.2.

4.1.1 Threatened and Endangered Plants

There are 13 federally and/or state threatened and endangered plant species reviewed to have a potential to occur within the geographical vicinity of the project area (CDFW 2015a; CNPS 2015) (Appendix C). Each of these listed species is presumed absent based on the absence of suitable habitat within the study area, the species being extirpated from the region, and/or recent negative floristic surveys at the adjacent Ballona Wetlands (Johnson 2012).

4.1.2 Non-Listed Special-Status Plants

A total of 34 federal and/or state non-listed special-status plants were reviewed to have a potential to occur within the geographical vicinity of the project area (CDFW 2015a; CNPS 2015) (Appendix C). Non-listed special-status plant species include those species that do not receive protection from state and/or federal endangered species legislation, but are covered in the CEQA process because of their rarity. The following three species were determined to be present within the study area.

Wooly Seablite (*Suaeda taxifolia*)

Wooly seablite is a CNPS CRPR 4.2 species found in coastal bluff scrub, coastal dunes, and margins of coastal salt marshes between the elevation ranges of 0–165 feet. Coastal salt marsh and coastal dunes suitable for this species occurs within the study area. This species was observed during the habitat assessment and is confirmed present within the study area.

Southwestern Spiny Rush (*Juncus acutis* ssp. *leopoldii*)

Southwestern spiny rush is a CNPS CRPR 4.2 species found in coastal dunes, meadows and seeps, and coastal salt marshes between the elevation ranges of 10–2,925 feet. Coastal salt marsh and coastal dunes suitable for this species occurs within the study area. This species was observed during the habitat assessment and is confirmed present within the study area.

Red Sand Verbena (*Abronia maritima*)

Red sand verbena is a CNPS CRPR 4.2 species found in coastal dunes between the elevation ranges of 0–325 feet. Coastal dunes suitable for this species occurs within the study area. This species was observed during the habitat assessment and is confirmed present within the study area.

4.1.3 Sensitive Vegetation Communities

Three sensitive vegetation communities as defined by CDFW occur within the project vicinity: Southern Coastal Bluff Scrub, Southern Coastal Salt Marsh, and Southern Dune Scrub (Holland 1986). Each of these communities occurs within the study area; however, only Southern Coastal Salt Marsh occurs within the disturbance footprint (Figure 4). Southern Coastal Salt Marsh is generally synonymous with *Sarcocornia pacifica* Herbaceous Alliance (Pickleweed Mats) and *Distichilis spicata* Herbaceous Alliance – Disturbed (Salt Grass Flats – Disturbed) as described by Sawyer et al (2009). Southern Coastal Salt Marsh is generally a collection of vegetation community series, which includes pickleweed series, cordgrass series, and saltgrass series. Both pickleweed and saltgrass series occur within the project disturbance footprint.

K:\Irvine\GIS\Projects\LABOE\00476 15\mapdoc\Fig04 Disturbance Footprint.mxd Date: 8/19/2016 37937

Figure 4
Disturbance Footprint
Venice Auxiliary Pumping Plant Project

4.2 Special-Status Wildlife

Habitat assessments for all special-status wildlife species evaluated are presented in Appendix C. Of the 37 special-status species evaluated, four species were determined to have a potential to occur within the study area: El Segundo blue butterfly (*Euphilotes battoides allyni;* FE), Belding's savannah sparrow (*Passerculus sandwichensis beldingi*; SE), light-footed clapper rail (*Rallus longirostris levipes*; FE, SE, SFP), and California least tern (*Sternula antillarum browni*; FE, SE, CFP).

4.2.1 Threatened and Endangered Wildlife

There are 22 federally and/or state listed wildlife species reviewed to have potential to occur within the geographical vicinity of the project area (CDFW 2015a) (Appendix C). Four of these species are judged to have a potential for occurrence within the study area based on current habitat conditions and are discussed in more detail below. No USFWS-designated critical habitat for federally threatened and/or endangered wildlife species is present within the study area (USFWS 2015).

El Segundo Blue Butterfly (*Euphilotes battoides allyni*)

El Segundo blue butterfly is designated as a federally endangered species. This species is found in coastal dune habitat where the host plant, bluff buckwheat, is present. Bluff buckwheat occurs within a restored area along the western portion of Ballona Lagoon in the southwest portion of the study area. None is present within the disturbance footprint. Approximately 30 El Segundo blue butterfly individuals were observed in July 2011 at the neighboring Ballona Wetland in a recently restored area approximately 1.3 miles from the study area (Johnson 2012). Based on the limited amount of host plant and very small population at the adjacent Ballona Wetlands, there is a low potential for this species to occur within the study area.

Belding's Savannah Sparrow (*Passerculus sandwichensis beldingi*)

Belding's savannah sparrow is a state endangered, non-migratory resident of coastal saltmarsh. This species is an obligate breeder in middle elevation saltmarsh dominated by pickleweed, in or adjacent to, tidal or non-tidal flats. Belding's savannah sparrow forages in a wide variety of habitats including upper marsh, adjacent ruderal and ornamental vegetation, open beach and mudflat, and even dirt and gravel parking lots. This species is known to breed within the neighboring Ballona Wetlands (Johnson 2012), but is not known to breed within the study area and no records of occurrence are known within the study area (CNDDB 2015). Therefore, this species has a low potential to breed within the study area. It has a moderate potential to forage within the study area due to the isolated nature of the study area and a limited amount of quality foraging habitat.

Light-Footed Clapper Rail (*Rallus longirostris levipes*)

Light-footed clapper rail is a designated federally endangered, state endangered, and state fully protected species. This subspecies of clapper rail is restricted to the lower elevations of coastal marshes with active tidal flow and dense pickleweed or cordgrass thickets. This species is typically a non-migratory resident. It is known to breed within the neighboring Ballona Wetlands (Johnson 2012), but is not known to breed within the study area and no records of occurrence are known within the study area (CNDDB 2015). In addition, the study area is relatively isolated from the

nearby breeding area. Therefore, this species has low potential to breed or forage within the study area.

California Least Tern (*Sternula antillarum browni*)

California least tern is a designated federally and state endangered species and fully protected state species. It nests on sandy upper ocean beaches, open barren sites, and occasionally uses mudflats. A large breeding colony is present at a neighboring fenced breeding area at Venice Beach, located approximately 0.6 miles to the southwest of the project site. This species has a less than reasonable potential to breed within the study area due to lack of suitable habitat and nearby suitable breeding grounds; however, it has a high potential to occur as a forager within the study area.

4.2.2 Essential Fish Habitat

The National Marine Fisheries Service Essential Fish Habitat mapper was reviewed to determine the presence of mapped Essential Fish Habitat (NOAA 2015). Neither Grand Canal nor Ballona Lagoon is mapped as Essential Fish Habitat. The nearest mapped Essential Fish Habitat is Marina del Rey, located approximately 4,200 feet to the south at the intersection of Ballona Lagoon and Marina del Rey Channel.

4.2.3 Non-Listed Special-Status Animals

Non-listed special-status species referred to herein include those wildlife species that are designated as a California Species of Special Concern, as defined by CDFW. There are 15 non-listed special-status species reviewed to have some potential to occur within the geographical vicinity of the project area (CDFW 2015a) (Appendix C). None of these species are judged to have a potential for occurrence based on current habitat conditions within the study area.

4.3 Nesting Birds

All developed and undeveloped portions of the study area contain suitable nesting habitat for a variety of avian species including, but not limited to, those species observed during the habitat assessment. During the habitat assessment, no birds were observed nesting as it was outside of the breeding season.

4.4 Raptor Foraging

The study area was evaluated for its potential to support raptor foraging activities. Except for a single osprey, no raptors or raptor nests were observed within or in the vicinity of the project site during the site visit. Due to the lack of expansive open areas, the study area would generally not be considered high quality raptor foraging habitat, although it provides foraging opportunities for some raptors that occupy developed areas.

4.5 Wildlife Corridors

No wildlife corridors are identified within the study area as a result of the surrounding urban development and lack of habitat connectivity and upstream hydrological connectivity to any other aquatic resource. Grand Canal and Ballona Lagoon provide refuge for aquatic species; however, neither function as a wildlife corridor since they connect only to the Marina del Rey Channel.

4.6 Environmentally Sensitive Habitat Areas (ESHA)

Grand Canal and Ballona Lagoon are classified as an ESHA by the CCC and County of Los Angeles because of their plant and wildlife resources within the local ecosystem. Portions of the Ballona Lagoon have been restored and have increased the functions and values of biological resources within the portion of the ESHA where the project is proposed (Hamilton 2010).

Chapter 5
Impacts

5.1 Thresholds of Significance

The City of Los Angeles includes the following CEQA thresholds to determine if a project would have a significant impact on biological resources. A project would normally have a significant impact on biological resources if it could result in the following:

- The loss of individuals, or the reduction of existing habitat, of a state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat;
- The loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community;
- Interference with habitat such that normal species behaviors are disturbed (e.g., from the introduction of noise, light) to a degree that may diminish the chances for long-term survival of a sensitive species;
- The alteration of an existing wetland habitat; or
- Interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species.

5.2 Impacts

Direct impacts occur when sensitive biological resources are altered through project implementation, such as through vegetation removal, habitat modifications, and injury or death of wildlife species. Indirect impacts may occur from elevated levels of noise or lighting, changes in surface water hydrology, or increased erosion or sedimentation. These types of indirect impacts can affect vegetation communities or their potential use by sensitive wildlife species.

The proposed project includes temporary direct impacts to the Grand Canal, its banks, and adjacent undeveloped lots to be used as construction laydown areas (Figure 4). The installation of project components, including the coffer dam diversion structure and 66-inch sewer connection within the Grand Canal, will occur below the existing grade of the channel and the work area will be restored to original contours following construction. Grand Canal will also receive increased light exposure from temporary construction lighting that will be installed to prevent incursion into the construction area. Temporary indirect impacts may occur during construction and include increased sedimentation as a result of installation and removal, minor alteration of surface water hydrology within the Grand Canal from the coffer dam that partially obstructs the canal, construction noise and lighting, as well as dust and other particulates that may become airborne during construction. Permanent direct impacts within the study area are limited to areas that are currently developed. No natural habitats would receive direct permanent impacts with the exception of habitat within Grand Canal that could be subject to permanent lighting installed on the new facility. The lighting

may increase the amount of permanent ambient light within Grand Canal. An increase in light could expose wildlife to increased detection and predation and could also deter some wildlife from utilizing the immediate area around the proposed facility lighting. The following sections describe in more detail temporary and permanent short-term and long-term direct and indirect impacts to vegetation communities and other sensitive biological resources anticipated as a result of the proposed project.

5.2.1 Impacts on Vegetation Communities

Temporary and permanent direct impacts to vegetation communities are provided in Table 3. The project will result in a total of 0.14 acre of short-term temporary direct impacts to vegetation communities (excluding developed areas). These impacts would occur during the construction phase only and no operational temporary direct impacts will occur. No permanent direct impacts to vegetation communities will occur. Approximately 0.02 acre of temporary direct impacts will occur to the sensitive vegetation community Southern Coastal Salt Marsh, which is generally synonymous with *Sarcocornia pacifica* Herbaceous Alliance (Pickleweed Mats) and *Distichilis spicata* Herbaceous Alliance – Disturbed (Salt Grass Flats – Disturbed) as described by Sawyer et al (2009). These impacts are potentially significant without mitigation. Mitigation Measures BIO-2, BIO-3, and BIO-7 (see Section 6) will ensure that the project will not cause the loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community Therefore, impacts to this sensitive vegetation community are less than significant with mitigation incorporated.

Table 3. Temporary and Permanent Impacts to Vegetation Communities/Land Uses/Land Conditions /Land Uses within the Study Area

Vegetation Community/Land Use/Land Condition	Temporary Impacts (acres)	Permanent Impacts (acres)
Developed (Vegetation Community)	0.17	0.27
Disturbed/Ruderal	0.12	-
Open water	0.06	
Southern Coastal Salt Marsh)	0.02	-
Coastal Brackish Marsh	0.003*	-
Southern Foredunes	-	-
Southern Coastal Bluff Scrub	-	-
Total	**0.37**	**0.27**

*Temporary impacts are negligible and this community will be avoided during project construction. Mitigation Measures BIO-2, BIO-3, and BIO-7 will also be implemented.

5.2.2 Impacts on Special-Status Plants

Each of the state and/or federally listed threatened and/or endangered plant species with records of occurrence within the project vicinity are presumed absent within the study area based on the lack of suitable habitat, and as a result, no impacts to listed plant species is anticipated. Three non-listed plant species were observed within the study area: woolly seablite, southwestern spiny rush, and red sand verbena, each of which is classified as a CNPS CRPR List 4.2 species (plants of limited

distribution). Although these species were observed in the study area, they are currently absent within the disturbance footprint, and as a result, no impacts to individuals or populations are anticipated. If these species were to inhabit the disturbance footprint, then impacts could be significant. Mitigation Measure BIO-1 (see Chapter 6) will ensure the project will not have a substantial adverse effect, either directly or through habitat modifications, or result in the loss of individuals, or the reduction of existing habitat, of a local, state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat. Therefore, impacts to special-status plants are less than significant with mitigation incorporated.

5.2.3 Impacts on Special-Status Wildlife

This section addresses impacts to special-status species with potential to occur within the study area. Impacts to special-status species would be significant without mitigation measures implemented. With the implementation of mitigation measures, the project will not have a substantial adverse effect, either directly or indirectly or through habitat modifications, or result in the loss of individuals, or the reduction of existing habitat, of a local, state or federal listed endangered, threatened, rare, protected, or candidate species, or a Species of Special Concern or federally listed critical habitat. Furthermore, with the implementation of mitigation measures, the project would not cause an interference with habitat such that normal species behaviors are disturbed (e.g., from the introduction of noise, light) to a degree that may diminish the chances for long-term survival of a sensitive species.

El Segundo Blue Butterfly (*Euphilotes battoides allyn*)

Based on the lack of suitable habitat and host plant within the project footprint, no temporary or permanent direct or indirect impacts to El Segundo blue butterfly are anticipated during construction or in operation. It is possible that stray individuals could temporarily occupy the adjacent restoration area along the western portion of Ballona Lagoon outside of the project footprint; however, no temporary direct or indirect impacts would occur given the disturbance footprint is approximately 390 feet northeast from the closest habitat containing the host plant. Impacts to this species could be potentially significant if the host plant inhabits the disturbance footprint. Although the host plant is not a sensitive species, BIO-1 would ensure that no host plants have established within the disturbance footprint prior to construction. Therefore, impacts to special-status wildlife are less than significant with mitigation incorporated.

Belding's Savannah Sparrow (*Passerculus sandwichensis beldingi*)

No permanent direct or indirect impacts to Belding's savannah sparrow would occur as a result of the project during construction or in operation due to restoration of the disturbance footprint following construction. BIO-3 would ensure that permanent direct impacts would be less than significant. Belding's savannah sparrow has a moderate potential to forage within the study area due to the nearby population at Ballona Wetlands, although the species has not been observed within Ballona Lagoon or Grand Canal and no records of occurrence are known within the study area (CNDDB 2015). Therefore, direct or indirect temporary impacts to this species are not anticipated. BIO-2 would ensure that no temporary impacts will occur to Belding's savannah sparrow. Therefore, impacts to special-status wildlife are less than significant with mitigation incorporated.

Light-Footed Clapper Rail (*Rallus longirostris levipes*)

No permanent direct or indirect impacts to light-footed clapper rail would occur as a result of the project during construction or in operation due to restoration of the disturbance footprint within Grand Canal following construction. BIO-3 would ensure that permanent direct impacts would be less than significant. Light-footed clapper rail has a low potential to forage within the study area due to the nearby population at Ballona Wetlands. However, the study area is relatively isolated and this species has not been observed within Ballona Lagoon or the Grand Canal and no records of occurrence within the study area are known (CNDDB 2015). Therefore, direct or indirect temporary impacts to this species are not anticipated. BIO-2 would ensure that no temporary impacts will occur to light-footed clapper rail. Therefore, impacts to special-status wildlife are less than significant with mitigation incorporated.

California Least Tern (*Sternula antillarum browni*)

No permanent direct or indirect impacts to California least tern would occur as a result of the project during construction or in operation due to restoration of the disturbance footprint following construction. BIO-3 would ensure that permanent direct impacts would be less than significant. California least tern has a less than reasonable potential to breed within the study area due to lack of suitable habitat and nearby suitable and protected breeding grounds approximately 0.6 miles from the study area; therefore, direct or indirect temporary impacts to breeding California least tern are not anticipated during construction or in operation. Installation of the coffer dam could cause an increase in turbidity that could have temporary indirect impacts on California least tern foraging either by reducing local prey availability and/or by reducing visibility of prey in the vicinity. Any construction activities conducted during the California least tern nesting season when terns are present could also cause temporary impacts in the form of noise and increased human disturbance that may attract tern predators such as the American crow and common raven. These predators could result in nest predation within the tern colony. Impacts to this species could be potentially significant. BIO-2, BIO-4, and BIO-5 would ensure that impacts to foraging California are least tern less than significant. Therefore, impacts to special-status wildlife are less than significant with mitigation incorporated.

5.2.4 Impacts on Nesting Birds

The study area and disturbance footprint support marginally suitable habitat for nesting birds, and as a result, direct and indirect temporary impacts to nesting species within the study area could potentially occur during construction. The areas to be affected potentially support nesting habitat only for ground-nesting birds, such as black-necked stilt (*Himantopus mexicanus*) and killdeer (*Charadrius vociferous*), as well as a habitat for a few species that commonly nest in structures and trees in developed areas. Impacts to nesting birds could be potentially significant. Impacts to nesting birds are protected under the *Migratory Bird Treaty Act* and *California Fish and Game Code* Sections and a nesting bird survey will be conducted during the nesting bird season and prior to any disturbance within the study area to document the presence or absence of nesting birds. Following construction, the project disturbance footprint within Grand Canal will be restored to original conditions. No operational impacts on nesting birds would occur. BIO-2, BIO-4, and BIO 6 will ensure that impacts on nesting birds will be less than significant with mitigation incorporated should the project occur during the nesting season.

5.2.5 Impacts on Raptor Foraging

Raptors such as osprey, Cooper's hawk, and red-tailed hawk are generally not expected to nest within the study area due to the disturbed and developed nature of the project; however, limited foraging habitat does occur for some raptor species. Because the project impacts within natural habitats are limited to a relatively small and defined portion of the Grand Canal and to a lesser extent Ballona Lagoon within the context of an urban environment and are temporary in nature, they are not considered significant. No operational impacts on nesting birds would occur. BIO-2 and BIO 6 will ensure that impacts on raptors will be less than significant.

5.2.6 Impacts on Wildlife Corridors

Construction of the project will include installation of a coffer dam that will partially block the Grand Canal; however, hydrological connectivity between upstream and downstream will remain in place throughout construction. Therefore, the project will not result in interference with wildlife movement/migration corridors that may diminish the chances for long-term survival of a sensitive species. Impacts on wildlife corridors will be less than significant.

5.2.7 Impacts on Jurisdictional Resources

The project occurs within the jurisdiction of several agencies including, but not limited to, USACE, RWQCB, and CCC and will result in temporary direct and indirect impacts to aquatic resources, including an existing wetland habitat. These impacts are significant without mitigation. No permanent direct or indirect impacts will occur. Table 4 below and Figure 5 identify temporary impacts to jurisdiction regulated by each of the agencies. Applicable permits from resource agencies will be obtained during the permitting phase prior to construction and all permit conditions and avoidance and minimization measures will be implemented. BIO-3 and BIO-5 will ensure that project impacts are less than significant with mitigation incorporated. Therefore, impacts associated with alteration of an existing wetland habitat are less than significant with mitigation incorporated.

Table 4. Temporary Impacts to Aquatic Resources (acres)

Study Area Feature	USACE Section 404 Non-Wetland Waters of the U.S./RWQCB Section 401 Non-Wetland Waters of the State	USACE Section 404 Wetland Waters of the U.S./RWQCB Section 401 Wetland Waters of the State	USACE Section 10 Navigable Waters of the U.S.	CCC 1-Parameter Wetlands
Ballona Lagoon and Grand Canal	0.092	0.012	0.056	0.092
Total	**0.092**	**0.012**	**0.056**	**0.092**

5.2.8 Impacts on Essential Fish Habitat

No designated Essential Fish Habitat is present within the study area; therefore; no impacts to Essential Fish Habitat will occur and no mitigation is required.

K:\Irvine\GIS\Projects\LABOE\00476_15\mapdoc\JD\Fig05_USACE.mxd Date: 8/25/2016 37937

Figure 5
USACE/RWQCB Jurisdictional Delineation Results Map
Venice Auxiliary Pumping Plant Project

5.2.9 Impacts on Environmentally Sensitive Habitat Areas

The Grand Canal and Ballona Lagoon are classified as an ESHA by the CCC and County of Los Angeles because of their plant and wildlife resources within the local ecosystem. Direct and indirect temporary impacts to ESHA will occur as a result of the project and are significant without mitigation. BIO-1 through BIO-9 will ensure that project construction and operation will not result in the loss of individuals or the reduction of existing habitat of a locally designated species or a reduction in a locally designated natural habitat or plant community. Therefore, impacts to ESHA will be less than significant with mitigation incorporated.

Chapter 6
Mitigation Measures

The following section provides specific mitigation measures to offset potential indirect or direct impacts on special-status species or resources. These mitigation measures will ensure that impacts on special-status biological resources would be mitigated to a level considered less than significant pursuant to CEQA.

MM-BIO-1: Special-Status Plant Surveys

To confirm the presence or absence of special-status plant species within the disturbance footprint, a special-status plant survey shall be completed prior to construction. The focused survey shall be conducted by a qualified biologist during the appropriate blooming period, or when the plant is readily identifiable, prior to the start of construction activities. If any sensitive non-listed plant species is found, then the individuals shall be clearly identified and avoidance measures shall be utilized to the extent practical.

MM-BIO-2: Monitoring During Vegetation Removal

A qualified biologist shall monitor all vegetation removal and ground-disturbing activities, such as staging and grading, for the duration of the project to ensure that practicable measures are being employed to avoid incidental disturbance of habitat outside the project footprint and to survey for sensitive wildlife species. When vegetation removal and ground-disturbing activities are not occurring, as-needed monitoring at the Project Site shall occur. Monitoring logs, as appropriate depending on project activities, shall be maintained for the duration of construction activities.

MM-BIO-3: Restoration of Vegetation within Grand Canal

Regarding the disturbance footprint within the Grand Canal, habitat along the bank shall be restored to its original condition by seeding, cuttings and/or container plant installation following construction. Habitat restoration shall be performed in coordination with regulating agencies (CCC, USACE, and RWQCB) and as required by agency permits. A habitat restoration plan shall be prepared and submitted to the Environmental Management Group for review and approval, prior to submittal to the agencies. The plan will include a native plant palette, and establishment period, as well as success criteria and monitoring requirements. In addition, a monetary contribution will be provided to the Grand Canal Restoration Project fund for wider restoration of the canal banks.

MM-BIO-4: Covered Disposal Containers

Work crews shall properly dispose of all garbage in covered containers to avoid attracting predators (such as crows and ravens) that could contribute indirectly to depredation of California least tern eggs and chicks in the nearby nesting colony.

MM-BIO-5: Water Quality Monitoring During Construction

Water quality shall be monitored by the qualified biologist or a water quality specialist to ensure that no substantial increases in turbidity occur during construction. The contractor shall ensure

compliance with RWQCB Section 401 Water Quality Certification, USACE Section 404 authorization, applicable water-quality related Best Management Practices, and the project Storm Water Pollution Prevention Plan.

MM-BIO-6: Nesting Bird Survey

If construction commences during the bird breeding season (February 15 through August 31), a preconstruction survey for nesting birds shall occur within three days prior to construction activities by an experienced avian biologist. The survey shall occur within all suitable nesting habitat within the project impact area and a 500-foot buffer. If nesting birds are found, an avoidance area shall be established in consultation with the resource agencies as appropriate by a qualified biologist around the nest until a qualified avian biologist has determined that young have fledged or nesting activities have ceased. The Project Site shall be re-surveyed if there is a lapse in construction activities for more than seven days during the bird breeding season.

MM-BIO-7: Silt Fencing at Construction Limits

Construction limits shall be identified using silt fencing, which shall be installed under the supervision of a qualified biologist prior to the commencement of work. Construction personnel shall strictly limit their activities, vehicles, equipment, and construction materials to the project footprint, including designated staging areas, and routes of travel. The construction areas shall consist of the minimal area necessary to complete the Proposed Project. The fencing shall remain in place until the completion of all construction activities.

MM-BIO-8: ESHA Protection

Existing functions and values in ESHA shall be protected, enhanced, and restored as necessary to previous undisturbed conditions in accordance with applicable USACE, RWQCB, CCC, or City of Los Angeles permits and requirements.

MM-BIO-9: Restoration of Mudflats within Grand Canal

The temporary work area within Grand Canal within mudflat/open water shall be returned to pre-construction grade and contours following construction.

Appendix B

Floral Compendium and Wildlife Observed

Plant Species Observed During 2015 Habitat Assessment Survey

Scientific Name	Common Name	Special Status
CHLOROPHYTA		
Ulvaceae		
Ulva intestinalis	Gut Weed	
Ulva lactuca	Sea Lettuce	
ANTHOPHYTA		
Aizoaceae - Fig-marigold family		
* *Aptenia cordifolia*	Baby sun-rose	
* *Carpobrotus edulis*	Hottentot fig	
Anacardiaceae - Sumac Or Cashew family		
Rhus integrifolia	Lemonade berry	
* *Schinus terebinthifolius*	Brazilian pepper tree	
Asteraceae - Sunflower family		
Ambrosia chamissonis	Beach bur-sage	
Ambrosia psilostachya	Western ragweed	
Ambrosia sp.	Ragweed	
Artemisia californica	California sagebrush	
Encelia californica	California encelia	
* *Erigeron bonariensis*	Flax-leaved horseweed	
* *Glebionis coronaria*	Crown daisy	
Heterotheca grandiflora	Telegraph weed	
Isocoma menziesii	Coastal goldenbush	
Jaumea carnosa	Marsh sunflower	
* *Sonchus asper ssp. asper*	Prickly sow thistle	
Bataceae - Saltwort family		
Batis maritima	Saltwort, beachwort	
Boraginaceae - Borage family		
Heliotropium curassavicum	Alkali heliotrope	
Cactaceae - Cactus family		
Opuntia littoralis	Coastal prickly pear	
Caryophyllaceae - Pink family		
Cerastium sp.	Mouse-ear chickweed	
Chenopodiaceae - Goosefoot family		
Arthrocnemum subterminale	Parish's pickleweed	
Atriplex lentiformis	Big saltbush	

Scientific Name	Common Name	Special Status
* *Atriplex prostrata*	Fat-hen	
* *Atriplex semibaccata*	Australian saltbush	
Atriplex watsonii	Watson's saltbush	
* *Bassia hyssopifolia*	Fivehorn smotherweed	
* *Chenopodium album*	Lamb's quarters	
Salicornia pacifica	Pacific pickleweed	
Suaeda taxifolia	Woolly seablite	CRPR 4.2
Convolvulaceae - Morning-glory family		
Cuscuta salina	Salt dodder	
Euphorbiaceae - Spurge family		
Euphorbia albomarginata	White margin spurge	
* *Euphorbia maculata*	Spotted spurge	
Fabaceae - Legume family		
Acmispon glaber	Deerweed	
Vicia sp.	Vetch	
Frankeniaceae - Frankenia family		
Frankenia salina	Alkali heath	
Geraniaceae - Geranium family		
* *Erodium moschatum*	Whitestem filaree	
Lythraceae - Loosestrife family		
* *Lythrum hyssopifolia*	Grass Poly	
Malvaceae - Mallow family		
* *Malva parviflora*	Cheeseweed	
Myrtaceae - Myrtle family		
* *Eucalyptus sp.*	Gum	
Nyctaginaceae - Four O'clock family		
Abronia maritima	Red sand-verbena	CRPR 4.2
Onagraceae - Evening Primrose family		
Camissoniopsis cheiranthifolia	Beach evening-primrose	
Polygonaceae - Buckwheat family		
Eriogonum parvifolium	Seacliff buckwheat	
Scrophulariaceae - Figwort family		
* *Myoporum laetum*	Ngaio tree	
Solanaceae - Nightshade family		
Solanum americanum	White nightshade	

Scientific Name	Common Name	Special Status
Zygophyllaceae - Caltrop family		
* *Tribulus terrestris*	Puncturevine	
Arecaceae - Palm family		
* *Washingtonia robusta*	Mexican fan palm	
Juncaceae - Rush family		
Juncus acutus ssp. leopoldii	Southwestern spiny rush	CRPR 4.2
Poaceae - Grass family		
* *Cynodon dactylon*	Bermuda grass	
Distichlis spicata	Salt grass	
Setaria sp.	Bristlegrass	

Legend

*= Non-native or invasive species

Special Status:

Federal:
FE = Endangered
FT = Threatened

State:
SE = Endangered
ST =Threatened

CRPR – California Rare Plant Rank
1A. Presumed extinct in California and elsewhere
1B. Rare or Endangered in California and elsewhere
2A. Presumed extinct in California, more common elsewhere
2B. Rare or Endangered in California, more common elsewhere
3. Plants for which we need more information - Review list
4. Plants of limited distribution - Watch list

Threat Ranks
.1 - Seriously endangered in California
.2 – Fairly endangered in California
.3 – Not very endangered in California

Plant Species Observed During LADPW 2005 Surveys Not Observed During 2015 Survey

Scientific Name	Common Name	Special Status
EUDICOTS		
Aizoaceae - Fig-marigold family		
Sesuvium verrucosum	Western sea-purslane	
Asteraceae - Sunflower family		
Erigeron canadensis	Horseweed	
* *Helminthotheca echioides*	Bristly ox-tongue	
* *Sonchus oleraceus*	Common sow thistle	
* *Taraxacum officinale*	Common dandelion	
Caryophyllaceae - Pink family		
* *Spergularia media var. media*	Greater sand-spurrey	
Chenopodiaceae - Goosefoot family		
* *Chenopodium macrospermum*	Largeseed goosefoot	
* *Chenopodium murale*	Nettleleaf goosefoot	
* *Dysphania botrys*	Clustered goosefoot	
Suaeda californica	California seablite	FE, CRPR 1B.1
Fabaceae - Legume family		
* *Melilotus sp.*	Sweetclover	
Geraniaceae - Geranium family		
* *Erodium cicutarium*	Redstem filaree	
Malvaceae - Mallow family		
* *Malva neglecta*	Common mallow	
Plantaginaceae - Plantain family		
* *Plantago major*	Common plantain	
Polygonaceae - Buckwheat family		
* *Polygonum aviculare ssp. depressum*	Dented oval leaf knotweed	
Rosaceae		
* *Rhaphiolepis indica*	Indian hawthorn	
MONOCOTS		
Poaceae - Grass family		
* *Digitaria ischaemum*	Smooth cottontop	
* *Stenotaphrum secundatum*	Saint augustine grass

Appendix C

Special-Status Species Table

Appendix C
Special-Status Species Information

This appendix addresses all species with applicable special regulatory or management status whose general range includes the study area or whose habitat occurs within or near the study area and/or vicinity. Information provided includes: 1) definitions of terms to describe likelihood of occurrence, 2) a table of special-status codes and their meanings, and 3) a species information table listing the English and scientific names, current special-status, likelihood of occurrence within the project site, and specific notes relevant to likelihood of occurrence.

Conclusions provided in this report are limited to biology and do not address regulatory or management issues. For interpretation of this information under applicable laws, regulations, and court precedent, see the relevant portion(s) of the report. Judgments regarding likelihood of occurrence are based on evaluation of available biological information regarding regional and local conditions, species biology, available evaluations of the study area and vicinity, and professional experience conducting field investigations across California over many years. Though professional, such judgments are necessarily subjective at least in part.

Specific factors substantially affect likelihood of occurrence for individual species on any particular study area. These factors are relevant at multiple scales, including regionally, locally, and within the study area. These factors include the presence or absence of other particular species (e.g., predators and prey), climate, ongoing disturbances, historical land use, and other past disturbances such as fire history, surface and subsurface hydrology, soil texture and chemistry, study area and habitat size and topology (i.e., shape and fragmentation), past population fluctuations of the species in response to random and nonrandom events, and many other factors, including many not readily visible. Note that some species, including some amphibians and many birds and bats, can occur in multiple roles. Thus, likelihood of occurrence, habitat use, and abundance may vary accordingly.

Finally, note that likelihood of occurrence for a given species refers to a time scale of a few years up to perhaps 10 years under current or assumed resources and conditions.

Terms for Likelihood of Occurrence in the Study Area

Confirmed Absent

If the likelihood of occurrence is *confirmed absent*, the species is confirmed to be absent on the study area as a formal and/or practical matter. Most often, this is a determination based on negative results of a focused survey for the species conducted in appropriate habitat at appropriate time(s) of year, using biologically sound methods and qualified personnel. In the remaining cases, it may be based on a simple study area examination, where it is easily determined that the species is absent because of the study area context. For example, a tidal marsh insect would not occur in a dry mountainside study area, or a disturbance-intolerant chaparral shrub would not occur in a long-standing, degraded grassland study area located far from chaparral. When a species is confirmed absent, the relevant fieldwork in all cases was conducted within a timeframe sufficiently recent to conclude that the species remains absent, based on study area conditions and the species' known ecology. In most cases a specific, established survey protocol and/or guidelines have been followed.

Less than Reasonable/Presumed Absent

If the potential to occur is *less than reasonable or presumed absent*, the likelihood of occurrence, although remotely possible, is less than that required for any potentially applicable regulatory threshold. Further, the likelihood that the site is meaningfully valuable to any population(s) of this taxon is less than reasonable. The species may or may not include the study area within its current, general range. However, no appropriate, or adequately extensive, or effectively connected habitat is present. Neither the species nor any indication of its presence was detected. In some cases, based on the best available information, this likelihood may indicate that the study area has a very high probability of being outside of the species' current range. In all of the above cases, the species may not be definitively ruled out but is strongly believed to be absent based on professional evaluation of all available evidence. In some cases, the species may occur on rare occasions and in low numbers, but with no more than brief, incidental use of the study area; that is, the site is also judged to lack any important function for the species. Certainly, there are no substantial populations directly utilizing the study area at any time of year. Further evaluation should not normally be required.

Low

If the potential to occur is *low*, occurrence of the species is reasonable but unlikely because of some combination of facts. For example, 1) the study area was the subject of unsuccessful searches conducted under relevant and reasonable circumstances, 2) potential habitat present is marginal or minimal in extent, 3) the best available information suggests the species is absent from the study area, and/or 4) available information sheds no clear light on the species likelihood on the study area but it is known to be rare at best in the vicinity. Neither the species nor any indication of its presence was detected. Although individuals may have been missed, it is unlikely that substantial populations are present. Further evaluation should usually not be required for individual species except, in most cases, for biologically threatened or endangered species. Note, however, that where several non-listed species hold this status, a higher likelihood of occurrence for "one or more" will generally hold. This is due both to the increased number of species and the fact that an array of possibilities often correlates with greater site biodiversity and lower relevant (but not readily detected) disturbance levels.

Moderate

If the potential to occur is *moderate*, the study area is within the range of the species and contains potentially appropriate habitat. Neither individuals nor diagnostic sign were detected. It is nevertheless reasonable that some individuals may have been overlooked. The best available information on the species with regard to the study area is either very uncertain, or may be equally weighted for and against occurrence. Depending on local and special legal status, extent of habitat, and the nature and sensitivity of the project, focused surveys for the species may be warranted or presence may be assumed.

High

If the potential to occur is *high*, the study area is known to be within the range of the species and contains potential habitat with a high likelihood of occupancy. Although no individuals or diagnostic sign were detected during current fieldwork by a qualified observer, the species is likely to be present to some degree given the best available information. Depending on regulatory status, local

rarity, public interest, extent of habitat on the study area, and the nature of potential project impacts, a substantial basis may exist for either conducting focused surveys for the species or for assuming presence.

Confirmed Present

If the likelihood of occurrence is *confirmed present*, a qualified biologist or other reliable source has confirmed the presence of the species and there is no specific evidence that the species has subsequently become absent. Depending on the species and other information available, it may or may not be possible to determine, without further studies, what portions of the study area are currently in use.

Table C-1. Sensitive Plant Species

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Abronia maritima	Red sand verbena	CRPR 4.2	Coastal dunes. Elevation range: 0–325 feet. Blooms: February–November.	HP, P	**Confirmed Present**. This species was observed within the study area.
Arenaria paludicola	Marsh sandwort	FE, SE, CRPR 1B.1	Sandy openings within freshwater marshes and swamps. Elevation range: 9–510 feet. Blooms: May–August.	HA	**Presumed Absent**. Present in the project region, but not known from the study area. Closely associated with freshwater wetland habitat, which is not present in the study area. Last southern California record is from 1899. Known from only two natural occurrences in Black Lake Canyon and at Oso Flaco Lake.
Astragalus brauntonii	Braunton's milk-vetch	FE, CRPR 1B.1	Recent burned or disturbed areas within chaparral, coastal scrub, and valley and foothill grasslands. Usually associated with sandstone or carbonate substrates. Elevation range: 12–1,920 feet. Blooms: January–August.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. This is a primarily chaparral species and the habitats in the study area do not provide suitable microsite conditions. Multiple surveys of the adjacent Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July 2010 and April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Astragalus pycnostachyus var. *lanosissimus*	Ventura Marsh milk-vetch	FE, SE, CRPR 1B.1	Coastal salt marsh, coastal dune, coastal scrub. Typically located within reach of high tide protected by barrier beaches and near seeps on sandy bluffs. Elevation range: 1–115 feet. Blooms: June–October.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area does not contain the barrier beaches and sandy bluffs that provide suitable microsite conditions for the species. Multiple surveys of the adjacent Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July 2010 and April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Astragalus tener var. *titi*	Coastal dunes milk-vetch	FE, SE, CRPR 1B.1	Vernally mesic areas within sandy coastal bluff scrub, coastal dunes, and mesic coastal prairie. Elevation range: below 165 feet. Blooms: March–May.	HA	**Presumed Absent**. Historically present in the project region but not known from the study area or adjacent Ballona Wetlands. Primarily a coastal prairie species, which does not occur in the study area. Multiple surveys of the study area conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Atriplex pacifica	South Coast saltscale	CRPR 1B.2	Coastal scrub, coastal bluff scrub, playas, chenopod scrub. Located on alkali soils. Elevation range: 0–460 feet. Blooms: March–October.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area does not contain the drier, steeper bluffs that provide suitable microsite conditions for the species. Multiple surveys of the adjacent Ballona Wetlands site conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Atriplex parishii	Parish's saltscale	CRPR 1B.1	Alkaline meadows, vernal pools, chenopod scrub, and playas. Usually on drying alkaline flats with fine soils. Elevation range: 80–6,160 feet. Blooms: June–October.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area is below the known elevation distribution.
Atriplex serenana var. *davidsonii*	Davidson's saltscale	CRPR 1B.2	Alkaline areas within coastal bluff scrub and coastal scrub. Elevation range: 30–650 feet. Blooms: April–October.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area does not contain the drier, steeper bluffs that provide suitable microsite conditions for the species. Multiple surveys of the adjacent Ballona Wetlands site conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Calochortus clavatus var. *gracilis*	Slender mariposa lily	CRPR 1B.2	Chaparral, coastal scrub, and valley and foothill grasslands. Elevation range: 1,180–3,280 feet. Blooms: March–June.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area is below the known elevation distribution.
Calochortus plummerae	Plummer's mariposa lily	CRPR 4.2	Sandy or rocky sites of granitic or alluvial material in valley and foothill grassland, coastal scrub, chaparral, cismontane woodland, and lower coniferous forests. Elevation range: 320–5,510 feet. Blooms: May–July.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area is below the known elevation distribution.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Calystegia felix	Lucky morning-glory	CRPR 3.1	Historically associated with wetland and marshy places but possibly in drier situations as well. Occurs in meadows and seeps (sometimes alkaline) and riparian scrub (alluvial). Elevation range: 90–650 feet. Blooms: March–September.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.
Camissoniopsis lewisii (=Camissonia lewisii)	Lewis's evening primrose	CRPR 3	Coastal bluff scrub, cismontane woodland, coastal dunes, coastal scrub, and valley and foothill grassland on sandy or clay soils. Elevation range: 0–975 feet. Blooms: March–May, sometimes June.	HP	**Moderate potential.** Suitable habitat is present within the study area. Although this species was not observed during surveys (August 2015), the field visit was outside of its blooming period. Several populations were mapped in the adjacent Ballona Wetlands during focused rare plant surveys in 2011 (Johnson 2012). Additionally, this species was observed during surveys by LABOE near 62nd Avenue and Pacific Street, south of the project area (personal communication W. Jones).
Centromadia parryi ssp. *australis*	Southern tarplant	CRPR 1B.1	Margins of marshes and swamps, vernally mesic valley and foothill grassland, and vernal pools. Often located on disturbed sites near the coast on alkali soils. Elevation range: 0–1,385 feet. Blooms: May–November.	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. Rare plant surveys in 2010 and 2011 at Ballona Wetlands did not detect this species (Johnson 2012).

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Chaenactis glabriuscula var. *orcuttiana*	Orcutt's pincushion	CRPR 1B.1	Coastal bluff scrub, coastal dunes. Located on sandy soils. Elevation range: 0–330 feet. Blooms: January–August.	HP	**Presumed Absent**. Although first documented from Ballona Wetlands in 1979 and found during focused rare plant surveys in 2011 (Johnson 2012), suitable habitat for this species only occurs outside of the project disturbance footprint within the 500-foot buffer. As such, it would not be impacted by the project. This species is known to occur within the adjacent Ballona Lagoon Restoration Area (Personal communication W. Jones 2016).
Chenopodium littoreum	Coastal goosefoot	CRPR 1B.2	Coastal dunes. Elevation range: 30–95 feet. Blooms: April–August.	HA	**Presumed Absent**. Historically present in the Ballona Wetlands. The study area contains small portions of restored coastal dune habitat that is potential habitat for this species; however, multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in 2010 and 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Chloropyron maritimum ssp. *maritimum (=Cordylanthus maritimus* ssp. *maritimus)*	Salt marsh bird's-beak	FE, SE, CRPR 1B.2	Coastal dune, marsh and swamp, coastal salt marsh, and wetland. Located on the higher zones of salt marshes. Elevation range: 0–100 feet. Blooms: May–October.	HP	**Presumed Absent**. Known historically from a 1901 collection from the region area; occurrence considered to be extirpated, based on surveys at Ballona Wetlands in 1980, 1982 and 1983; floristic rare plant surveys in July and October 2010 did not observe this species (Johnson 2012).
Chorizanthe parryi var. *fernandina*	San Fernando Valley spineflower	FC, SE, CRPR 1B.1	Coastal scrub and valley and foothill grasslands. Elevation range: 450–3,680 feet. Blooms: April–July.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Deinandra minthornii	Santa Susana tarplant	CRPR 1B.2	This deciduous shrub can be found in rocky chaparral and coastal scrub communities of Ventura and Los Angeles counties. Elevation range: 919–2,493 feet. Blooms: July–November.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.
Dithyrea maritima	Beach spectaclepod	ST, CRPR 1B.1	Coastal dunes, coastal scrub. Located at seashores on sand dunes and sandy places near the shore. Elevation range: 10–165 feet. Blooms: March–May.	HP	**Presumed Absent**. Historically present in the region and last observed in 1934; the study area contains small portions of restored coastal dune habitat that is potential habitat for this species; however, multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Dudleya cymosa ssp. *ovatifolia*	Santa Monica dudleya	FT, CRPR 1B.2	Chaparral, coastal scrub. Located in canyons on sedimentary conglomerates on primarily north-facing slopes. Elevation range: 485–5,430 feet. Blooms: March–June.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.
Dudleya multicaulis	Many-stemmed dudleya	CRPR 1B.2	Often on clay soils around granitic outcrops in chaparral, coastal sage scrub, and grasslands. Elevation range: 45–5,430 feet. Blooms: April–July.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Dudleya virens ssp. *insularis*	Island green dudleya	CRPR 1B.2	Coastal bluff scrub, coastal scrub. Located on rocky sites. Elevation range: 15–975 feet. Blooms: April–June	HA	**Presumed Absent**. Present in the project region but not known from the study area or adjacent Ballona Wetlands. The study area does not contain the drier, steeper bluffs that provide suitable microsite conditions for the species. Multiple surveys of the adjacent Ballona Wetlands site conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Eryngium aristulatum var. *parishii*	San Diego button-celery	FE, SE	Occurs in vernal pools and wetlands within coastal scrub, valley and foothill grassland, and wetland riparian communities. Elevation range: 60–1,860 feet. Blooms: April–June.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.
Erysimum insulare	Island wallflower	CRPR 1B.3	Coastal bluff scrub and coastal dune habitat. Elevation range: 0–985 feet. Blooms: March–July.	HP	**Moderate Potential.** Suitable habitat is present within the study area. Although this species was not observed during surveys (August 2015), the field visit was outside of its blooming period.
Helianthus nuttallii ssp. *parishii*	Los Angeles sunflower	CRPR 1A	Saltwater and freshwater marshes and swamps. Elevation range: 30–5,445 feet. Blooms: August–October.	HP	**Presumed Absent**. Historically present in the project region, but not known from the study area or adjacent Ballona Wetlands. Considered to be extirpated in California. Multiple surveys of the adjacent Ballona Wetlands site conducted since 1979, including floristic rare plant surveys in 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Hordeum intercedens	Vernal barley	CRPR 3.2	Coastal dunes, coastal scrub, valley and foothill grassland, vernal pools. Located on saline flats and depressions. Elevation range: 15–3,240 feet. Blooms: March–June.	HA	**Presumed Absent**. Historically present in the region, but not observed since 1901. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Horkelia cuneata var. *puberula*	Mesa horkelia	CRPR 1B.1	Sandy or gravelly soils in chaparral or rarely in cismontane woodlands or coastal scrub. Elevation range: 225–2,625 feet. Blooms: February–September.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.
Juncus acutus ssp. *leopoldii*	Southwestern spiny rush	CRPR 4.2	Coastal dunes, meadows and seeps, coastal salt marshes. Located on mesic, alkaline seeps and coastal salt. Elevation range: 10–2,925 feet. Blooms: May–June.	HP, P	**Confirmed Present**. This species was observed within the study area.
Lasthenia glabrata ssp. *coulteri*	Coulter's goldfields	CRPR 1B.1	Marshes, playas, vernal pools, and grasslands. Usually associated with alkaline soils. Elevation range: 1–3,955 feet. Blooms: February–June.	HP	**Presumed Absent**. Wetlands in the study area may provide suitable habitat for the species. However, although it was historically present in the region it has not observed since 1934. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Leptosyne maritima	Sea dahlia	CRPR 2B.2	Found in coastal bluff scrub and coastal scrub habitat. Located on a variety of soil types, including sandstone. Elevation range: 16–492 feet. Blooms: March–May.	HA	**Presumed Absent.** This species does not occur in the project region and study area is outside of the species range. The study area contains coastal scrub habitat, but not the drier, steeper bluffs that provide suitable microsite conditions for the species. Multiple surveys of the adjacent Ballona Wetlands, including floristic rare plant surveys in 2010 and 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Monardella hypoleuca ssp. *hypoleuca*	White-veined monardella	CRPR 1B.3	Found in chaparral and cismontane woodland. Located on dry slopes. Elevation range: 164–5,003 feet. Blooms: April–December.	HA	**Presumed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution.
Nama stenocarpa	Mud nama	CRPR 2B.2	Marshes and swamps. Located on lake shores, streambanks, and intermittently wet areas. Elevation range: 15–1,620 feet. Blooms: January–July.	HA	**Presumed Absent**. Historically present in the region but not observed since 1924. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in 2010 and 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Nasturtium gambelii	Gambel's water cress	FE, ST, CRPR 1B.1	Freshwater and brackish marshes and swamps. Elevation range: 16–1,083 feet. Blooms: April–October.	HP	**Presumed Absent**. Marshes in the study area may provide suitable habitat for the species. However, although it was historically present in the region it has not observed since 1906 and is not known from the study area. Multiple surveys of the Ballona Wetlands conducted since 1979, including focused rare plant surveys in July 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Navarretia fossalis	Spreading navarretia	FT, CRPR 1B.1	Chenopod scrub, marshes and swamps (shallow freshwater), playas, and vernal pools. Elevation range: 98–2,149 feet. Blooms: April–June.	HA	**Presumed Absent**. Known historically in the project region (last seen in 1904) but not known from the study area. Closely associated with freshwater wetland habitat, which is not present in the study area. Multiple surveys of the Ballona Wetlands conducted since 1979, including focused rare plant surveys in July 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Navarretia prostrata	Prostrate navarretia	CRPR 1B.1	Vernal pools, coastal scrub, meadows and seeps, and alkaline valley and foothill grassland. Elevation range: 95–4,225 feet. Blooms: April–June.	HA	**Presumed Absent**. Historically present in the region, but not observed since 1906. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). The study area is below the known elevation distribution.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Orcuttia californica	California Orcutt's grass	FE, SE, CRPR 1B.1	Vernal pools that remain ponded for longer than three weeks. Elevation range: 45–2,145 feet. Blooms: April–August.	HA	**Presumed Absent**. Known historically in the project region (last seen in 1946) but not known from the study area. Closely associated with freshwater wetland habitat, which is not present in the study area. Multiple surveys of the Ballona Wetlands conducted since 1979, including focused rare plant surveys in July 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Pentachaeta lyonii	Lyon's pentachaeta	FE, SE, CRPR 1B.1	Chaparral, valley and foothill grassland. Located on the edges of openings at the ecotone between chaparral and grassland. Elevation range: 95–2,050 feet. Blooms: March–August.	HA	**Presumed Absent**. Historically present in the region but not observed since 1884. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July 2010 and April 2011, did not observe this species (Johnson 2012). The study area is below the known elevation distribution.
Phacelia stellaris	Brand's star phacelia	FC, CRPR 1B.1	Coastal scrub and coastal dunes. Elevation range: below 1,200 feet. Blooms: March–June.	HP	**Presumed Absent**. Historically present in the region, but not observed since 1932. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Potentilla multijuga	Ballona cinquefoil	CRPR 1A	Perennial herb found in brackish meadows and seeps. Elevation range: 0–10 feet. Blooms: June–August.	HP	**Presumed Absent**. This species is known from only a single location. It was originally collected on the flats of Ballona (now called Venice) in 1890. No further observations of the species were made, and it is presumed to be extinct. Multiple surveys of the Ballona Wetlands conducted since 1979, including focused rare plant surveys in July 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Pseudognaphalium leucocephalum	White rabbit tobacco	CRPR 2.2	Sandy areas within chaparral, cismontane woodland, coastal scrub, riparian woodland. Elevation range: below 6,825 feet. Blooms: July–December.	HP	**Presumed Absent**. Coastal scrub habitat in the study area may be suitable habitat for this species. However, although known historically in the project region, this species was last recorded in 1907 and the study area occurs outside of the species range. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July and October 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Quercus dumosa	Nuttall's scrub oak	CRPR 1B.1	Evergreen shrub that inhabits sandy soils and clay loam in coastal scrub, chaparral, and closed-cone coniferous forests. It can be found along the coasts of Santa Barbara, Orange, and San Diego counties. Elevation range: 49–1,312 feet. Blooms: February–August.	HA	**Confirmed Absent**. No suitable habitat is present within the study area, and the study area is below the known elevation distribution. This species was not observed during field surveys.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Sidalcea neomexicana	Salt spring checkerbloom	CRPR 2B.2	Alkali playas, brackish marshes, chaparral, coastal scrub, lower montane coniferous forest, Mojavean Desert scrub. Located on alkali springs and marshes. Elevation range: 45–4,960 feet. Blooms: March–June.	HA	**Presumed Absent**. Brackish marsh in the study area may be suitable habitat for this species. However, the study area is below the known elevation distribution and outside of the species range. In addition, it known historically in the project region from only a single collection from 1890. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July 2010 and April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Suaeda esteroa	Estuary seablite	CRPR 1B.2	Coastal salt marshes and swamps. Located on clay, silt, and sand substrates. Elevation range: 0–15 feet. Blooms: May–January.	HP	**Presumed Absent**. Marshes in the study area may be suitable habitat for this species. However, it is not known to occur in the project region. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July and October 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Suaeda taxifolia	Wooly seablite	CRPR 4.2	Coastal bluff scrub, coastal dunes, margins of coastal salt marshes. Elevation range: 0–165 feet. Blooms: January–December	HP, P	**Confirmed Present**. The species is known to occur in the study area. Coastal salt marsh and coastal dunes in the study area are habitat for this species.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Symphyotrichum defoliatum	San Bernardino aster	CRPR 1B.2	Cismontane woodland, coastal scrub, coniferous forest, meadows and seeps, marshes and swamps, and mesic grassland near water. Elevation range: 5–6,630 feet. Blooms: July–November.	HA	**Presumed Absent**. No chaparral or woodland habitat is present in the study area. Known historically in the project region (last seen in 1932) but not known from the study area. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July and October 2010, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.
Symphyotrichum greatae	Greata's aster	CRPR 1B.3	Broadleaved upland forest, chaparral, cismontane woodland, lower cismontane coniferous forest, and riparian woodland. Elevation range: 975–6,535 feet. Blooms: June–October.	HA	**Presumed Absent**. Known historically in the project region (last seen in 1930) but not known from the study area. Coastal scrub habitats in the study area do not provide suitable habitat for this species and the study area is below the known elevation distribution.
Thelypteris puberula var. *sonorensis*	Sonoran maiden fern	CRPR 2B.2	Seeps and streams in meadows. From southern California south to Sonora, Mexico, and east to Arizona. Within California it is known from Santa Barbara, Los Angeles, Riverside, and San Bernardino counties. This fern is rare to uncommon in California but is more common outside of the state. Elevation range: 164–2,001 feet. Blooms: January–September.	HA	**Presumed Absent**. Not known to occur in the project region or study area and no suitable habitat occurs in the study area. Not observed during field surveys. Multiple surveys of the Ballona Wetlands conducted since 1979, including floristic rare plant surveys in July 2010 and April 2011, did not observe this species (Johnson 2012). Additionally, surveys done within the Grand Canal in November 2005 (LABOE 2005) and May 2009 (LABOE 2009) were also negative for the species.

P Species is present
HA Habitat is absent
HP Habitat is, or may be, present

Table C-2. Sensitive Wildlife Species

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Insects					
Euphilotes battoides allyni	El Segundo blue butterfly	FE	Historically ranged over the entire Los Angeles/El Segundo Dunes and the northwestern Palos Verdes Peninsula in southwestern LA County. Currently distributed on three remnant habitats within its former range supporting coastal sand dunes with host plant sea cliff buckwheat (*Eriogonum parvifolium*). All life stages depend on the host plant, as well as possibly loose sand.	HP	**Low Potential.** The study area contains the host plant *Eriogonum parvifolium* within a restoration area along the western portion of Ballona Lagoon although no host plant is present within the project footprint. Because approximately 30 individuals were observed in July 2011 at the adjacent Ballona Wetland (Johnson 2012), there is a potential for the species to occur within the study area, albeit low.
Glaucopsyche lygdamus palosverdesensis	Palos Verdes blue butterfly	FE	Restricted to the cool, fog-shrouded, seaward side of Palos Verdes Hills, Los Angeles County. The larval host plant, Southern California milkvetch (*Astragalus trichopodus* ssp. *lochus*), is typically found on clay soils on rocky slopes. Butterflies feed on milkvetch and deerweed.	HA	**Less than Reasonable.** The study area lacks suitable habitat and the host plant. Historical sightings include Malaga Cove in 2001 (approximately 10 miles to the south). Other sightings in CNDDB are from the 1980's and are considered possibly extirpated (CNDDB 2015).
Crustaceans					
Streptocephalus woottoni	Riverside fairy shrimp	FE	Found in shallow depressions containing a clay hard pan soil layer. Discontinuously distributed along coastal southern California and northern Baja California.	HA	**Less than Reasonable.** The study area lacks vernal pools or suitable clay hardpan with freshwater habitat.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Reptiles and Amphibians					
Anniella pulchra pulchra	Silvery legless lizard	SSC	Sandy or loose soils under sparse vegetation on beaches, within chaparral, pine-oak woodlands, sycamore and cottonwood woodland or oaks near stream terraces.	HP	**Less than Reasonable.** The study area lacks quality habitat and the isolated nature of the study area precludes this species from occurring.
Emys marmorata	Western pond turtle	SSC	Inhabits permanent or nearly permanent freshwaters. Requires basking sites (i.e., partially submerged logs, rocks, or open banks).	HA	**Less than Reasonable.** The study area lacks suitable vegetated freshwater habitat. No pond turtles were detected during surveys at the adjacent Ballona Wetlands from 1981 to 2011 (Johnson 2012).
Phrynosoma blainvillii	Coast horned lizard	SSC	Sandy areas within valley and foothill hardwood and conifer woodlands, riparian areas, coastal scrub, chaparral, and annual grasslands.	HA	**Less than Reasonable.** The study area lacks suitable loose sand and soil habitat. Documented CNDDB observations are greater than 5 miles away predominantly near Santa Monica mountains.
Rana draytonii	California red-legged frog	FT, SSC	Occurs very locally on the western slopes of the Sierra Nevada and the coastal foothills the length of the state, up to about 4,920 feet. Inhabits pools of streams, marshes, and ponds. Adults feed on a wide variety of aquatic prey and will move up to a mile through riparian communities under wet conditions, such as rainfall. They prefer shorelines with extensive vegetation and are vulnerable to the introduction of exotic competitors.	HA	**Less than Reasonable.** The study area lacks suitable freshwater habitat. This species has not been detected during any of the numerous studies conducted in the adjacent Ballona Wetlands over the past several decades (Johnson 2012).

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Spea hammondii	Western spadefoot	SSC	Open habitats including low grasslands, open chaparral, and pine-oak woodlands, where soils are sandy or gravelly. Requires temporary rain pools that last at least 3 weeks. Pools must lack predators of eggs and tadpoles.	HA	**Less than Reasonable.** The study area lacks suitable freshwater habitat.
Taricha torosa	Coast range newt	SSC	Breeds in ponds, reservoirs, and slow-moving streams. Uses nearby upland areas including grasslands, chaparral, and woodlands.	HA	**Less than Reasonable.** The study area lacks suitable freshwater habitat.
Thamnophis hammondii	Two-striped garter snake	SSC	Permanent streams with rocky beds that support riparian canopy.	HA	**Less than Reasonable.** The study area lacks suitable habitat. This species has not been detected during surveys at the adjacent Ballona Wetlands from 1981 to 2011 (Johnson 2012).
Fish					
Eucyclogobius newberryi	Tidewater goby	FE, SSC	Found primarily in waters of coastal lagoons, estuaries, and marshes, and historically ranged from mouth of the Smith River, Del Norte County to northern San Diego County. The species is benthic in nature, living at the bottom of shallow brackish bodies of water, such as lagoons and in lower stream reaches where the water is fairly still but not stagnant. Prefers water with high dissolved oxygen levels and salinities less than 10 parts per thousand.	HP	**Less than Reasonable.** Possible suitable habitat may occur within the study area and this species may have occurred historically; however, the species has not been detected during numerous studies over the last several decades within the adjacent Ballona Wetlands (Johnson 2012).

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Oncorhynchus mykiss irideus	Southern steelhead	FE, SSC	Permanent streams in coastal basins. Migrates into fresh water streams when sandbars breach during winter and spring rains. Occurs in coastal streams with water temperatures < 15°C. Needs cool, clear water with in-stream cover. Spawns in tributaries to large rivers or streams directly connected to the ocean. Spawning habitat consists of gravel substrates free of excessive silt. Thrives when dissolved oxygen concentration is at least 7 parts per million. In streams, deep low-velocity pools are important wintering habitats.	HA	**Less than Reasonable** Although individuals have been periodically observed in Ballona Creek (Johnson 2012), the study area and its tributaries are urbanized and provide no spawning conditions.
Siphateles bicolor mohavensis	Mohave tui chub	FE, SE	Deep pools or shallow outflow streams of mineralized, alkaline waters. Formerly in mainstream Mohave River; now in lakes and mineral spring pools. Dominant plants in habitat include ditchgrass, bulrush, cattail, rush, and saltgrass. Capable of surviving low oxygen (1 mg oxygen/L) and high alkaline (pH 9-10) environments.	HA	**Less than Reasonable.** Suitable conditions for this species not present in the study area. There is no historic record of occurrence of this species near the study area.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Birds					
Agelaius tricolor	Tricolored blackbird	SSC	Range is restricted to the Central Valley and surrounding foothills, throughout coastal and some inland localities in southern California. Breeds in dense colonies near freshwater, often in tall emergent wetland habitats with dense cattail or tule. Will also nest in thickets of willow, blackberry, wild rose, and tall herbs. May travel several kilometers to secure food for nestlings. Forages in grassland and cropland habitat. They are itinerant breeders, nesting more than once at different locations during the breeding season.	HA	**Less than Reasonable** as a breeder as the study areas lacks high quality breeding habitat for this species. The nearest historical nesting site is several miles inland near Torrance. **Less than Reasonable** as a forager as this species, with the exception of a regular wintering flock of several dozen birds in the vicinity of Westchester Park, is a casual visitor to the Ballona Valley.
Athene cunicularia	Burrowing owl	SSC	Level, open, dry, heavily grazed or low grassland or desert vegetation with available rodent or other large burrows. In coastal Southern California, found in microhabitats highly altered by humans, including flood control and irrigation basins, dikes, banks, abandoned fields surrounded by agriculture, and road cuts and margins.	HA	**Less than Reasonable** as a breeder or a forager as there is no suitable nesting habitat in the study area and this species has not been observed during the breading season at the adjacent Ballona Wetlands for decades (Johnson 2012).
Buteo swainsoni	Swainson's hawk	ST	Occurs in open habitats, including cropland and hedgerow, desert, grassland, savanna, and mixed woodland. Nests in solitary or small groups of trees in open areas where they forage. Breeds in the western United States and migrates through Central America to winter in Argentina and Brazil.	HA	**Less than Reasonable** as a breeder or a forager as the study area lacks suitable habitat.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Charadrius alexandrinus nivosus	Western snowy plover	FT, SSC	Breeds primarily above the high tide line on coastal beaches, sand spits, dune-backed beaches, sparsely vegetated dunes, beaches at creek and river mouths, and salt pans at lagoons and estuaries. In winter, found on beaches used for nesting and other beaches, in manmade salt ponds, and on estuarine sand and mud flats.	HA	**Less than Reasonable** as a breeder. This species has been extirpated as a breeding perennial resident from the region. **Less than Reasonable** as a forager as the study area lacks high quality foraging habitat for this species.
Coccyzus americanus occidentalis	Western yellow-billed cuckoo	FC, SE	Breeds and nests in extensive stands of cottonwood/willow riparian forest within large rivers with broad flood prone bottoms.	HA	**Less than Reasonable** as a breeder due to lack of habitat. **Less than Reasonable** as a forager as this species is a vagrant.
Empidonax traillii extimus	Southwestern willow flycatcher	FE, SE	Restricted to riparian woodlands along streams and rivers with mature, dense stands of willows, cottonwoods, or smaller spring-fed or boggy areas with willows or alders.	HA	**Less than Reasonable** as a breeder due to lack of habitat. **Less than Reasonable** as a forager as this species is a vagrant.
Grus canadensis tabida	Greater sandhill crane	ST	Sandhill cranes breed in the upper Midwest and Canada, winter in the southern U.S. and northern Mexico, and can be seen throughout the Great Plains and Pacific Northwest during migration. Winter foraging habitat includes irrigated croplands, pastures, grasslands, and wetlands with shallow lakes or rivers for night roosts. Three subpopulations of this species are non-migratory and found in Mississippi, Florida, and Cuba.	HA	**Less than Reasonable** as a breeder. The study area is outside of the species breeding range. **Less than Reasonable** as a forager as this species is considered extirpated from the region.
Gymnogyps californianus	California condor	FE, SE, SFP	Requires large areas of remote country for foraging and tall cliff faces for breeding. Forages in open grasslands and oak savanna foothills.	HA	**Less than Reasonable** as a breeder due to lack of habitat. **Less than Reasonable** as a forager as this species is considered extirpated from the region.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Laterallus jamaicensis coturniculus	California black rail	ST, SFP	Tidal salt marshes associated with heavy growth of tule and pickleweed; also occurs in brackish marshes or freshwater marshes at low elevations. Primarily restricted to the San Francisco Bay, with smaller numbers in wetlands from the Salton Sea area to Arizona.	HA	**Less than Reasonable** as a breeder or a forager as this species is deemed extirpated from the region.
Passerculus sandwichensis beldingi	Belding's savannah sparrow	SE	Locally common non-migratory resident of coastal saltmarsh. Obligate breeder in middle elevation saltmarsh, nearly always characterized by pickleweed, either in tidal situations or non-tidal alkaline flats nearby. The majority of its subsistence stems from the saltmarsh and closely adjacent mudflat. Also can be found foraging in a wide variety of habitats, including upper marsh, adjacent ruderal and ornamental vegetation, open beach and mudflat, and even dirt and gravel parking lots.	HP	**Low potential** as a breeder due to lack of high quality habitat within the study area. **Moderate potential** as a forager due to the isolated nature of the study area and limited amount of quality foraging habitat.
Polioptila californica californica	Coastal California gnatcatcher	FT, SSC	May be found in coastal sage scrub below 2,500 feet. Prefers low, coastal sage scrub in arid washes, mesas, and slopes.	HA	**Less than Reasonable** as a breeder or a forager due to lack of habitat.
Rallus longirostris levipes	Light-footed clapper rail	FE, SE, SFP	This subspecies of the large and widespread clapper rail is restricted to the lower elevations of coastal marshes with active tidal flow and dense pickleweed and/or cordgrass thickets from Hueneme, Ventura County (formerly to Santa Barbara County) south to Bahia de San Quintin, Baja California, Mexico. No substantial seasonal movements occur, although rare individuals wander away from known breeding locales.	HP	**Low potential** as a breeder. This species breeds within the adjacent Ballona Wetlands, but is not known to breed within the study area. **Low potential** as a forager as the study area is relatively isolated from the nearby breeding area.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Rallus longirostris obsoletus	California clapper rail	FE, SE	Occurs in marine and brackish water marshes with pickleweed and cordgrass.	HA	**Less than Reasonable** as a breeder or a forager due to lack of quality habitat and nearby breeding populations.
Riparia riparia	Bank swallow	ST	Nests on vertical banks along streams and rivers.	HA	**Less than reasonable** as a breeder due to lack of suitable nesting habitat. **Less than Reasonable** as a forager as this species is an occasional transient.
Sternula antillarum browni	California least tern	FE, SE, CFP	Nests on sandy upper ocean beaches, open barren sites, and occasionally uses mudflats. Forages on adjacent surf line, estuaries, or the open ocean. Colonies are located near the ocean shoreline (within 0.5 miles [about 800 meters]), typically on nearly flat, loose sandy substrates with lightly scattered short vegetation and debris, although some colonies have been located on hard-packed surfaces, even unused asphalt.	HP	**Less than Reasonable** as a breeder as suitable habitat is not present. A large breeding colony (up to 200–300 pairs) within fenced-off "tern preserve" is on Venice Beach just north of Ballona Creek mouth. **High potential** as a forager as this species is a common local summer resident, fishing offshore, along lower Ballona Creek., along tidal channels within Ballona Lagoon, and at the Ballona freshwater marsh.
Vireo bellii pusillus	Least Bell's vireo	FE, SE	Prefers dense riparian habitats but can also be found in more open riparian habitats such as mulefat scrub.	HA	**Less than Reasonable** as a breeder or a forager due to lack of habitat.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Mammals					
Antrozous pallidus	Pallid bat	SSC	Arid regions with suitable roosting habitat adjacent to large bodies of water to forage over. Suitable roosting habitat consists of rocky outcrops, caves, tunnels, mines, eaves, and tree hollows.	HA	**Less than Reasonable**. Roosting and foraging sites are lacking in the study area.
Eumops perotis californicus	Western mastiff bat	SSC	Many open, semi-arid to arid habitats, including conifer and deciduous woodlands, coastal scrub, grasslands, and chaparral. Roosts in crevices in cliff faces, high buildings, trees, and tunnels.	HA	**Less than Reasonable**. Roosting and foraging sites are lacking in the study area.
Microtus californicus stephensi	South coast marsh vole	SSC	Occurs in the area of tidal marshes in Los Angeles, Orange, and southern Ventura counties.	HA	**Less than Reasonable**. Although this species was captured during small mammal surveys in marsh habitats containing saltgrass (*Distichlis spicata*) in Ballona Wetlands (Johnson 2012), the lack of quality habitat and isolated nature of the study area preclude this species from occurring.
Nyctinomops femorosaccus	Pocketed free-tailed bat	SSC	Rocky desert areas with relatively high cliffs. Less frequently known to roost in buildings, caves, and under roof tiles.	HA	**Less than Reasonable**. Roosting and foraging sites are lacking in the study area.
Nyctinomops macrotis	Big free-tailed bat	SSC	Roosts are in deep tunnels or caves, occasionally in buildings or bridges. It was formerly found throughout southern California but is apparently now confined to lowland Sonoran Desert habitat below 1,800 feet. It forages in desert wash vegetation within 1 to 3 miles of roosting sites. Historical habitats used in coastal areas appear to be poorly known.	HA	**Less than Reasonable**. Roosting and foraging sites are lacking in the study area.

Scientific Name	Common Name	Status	General Habitat Description	Habitat Present/ Absent	Rationale
Perognathus longimembris pacificus	Pacific pocket mouse	FE, SSC	This species is an obligate resident of fine-grained sandy soils of Coastal Strand, Coastal Dunes, River and Marine Alluvium, and Coastal Sage Scrub close to the ocean, and it has never been collected more than 2 miles from the coast or above 600 feet in elevation. It appears that occurrences are closely associated with loose or friable soils that permit burrowing.	HP	**Less than Reasonable.** No detection in survey efforts in 1981–2011 within Ballona Wetlands (Johnson 2012). The study area contains some suitable habitat; however, the last noted detections in the region were in 1938.
Sorex ornatus salicornicus	Southern California saltmarsh shrew	SSC	Occurs in coastal marshes in Los Angeles, Orange, and Ventura counties. Based on other studies of shrews, may require dense ground cover and nesting sites above mean high tide and free from inundation.	HP	**Less than Reasonable**. Last captured in Ballona Wetlands in 1991 (Johnson 2012). Although some marginal suitable habitat is present within the study area, the isolated nature of the study area precludes this species from occurring.
Taxidea taxus	American badger	SSC	Open plains and fields, particularly in grasslands.	HA	**Less than Reasonable** due to lack of habitat. The closest occurrence is greater than 9 miles away. Urbanized and isolated setting precludes the species from occurring.

U.S. Fish and Wildlife Service		**California Department of Fish and Game**		**Habitat Present/Absent**

Chapter 1
Introduction

On September 21, 2015, ICF International (ICF) conducted a routine-level delineation of jurisdictional waters and wetlands within a portion of the Ballona Lagoon and Grand Canal for the Los Angeles Bureau of Engineering as part of the federal and state regulatory permitting process for activities to be conducted for the Venice Auxiliary Pumping Plant Project (project).

The purpose of this delineation is to identify the extent of federal, state, and local jurisdictions within and adjacent to the project site to support the resource-agency permitting process. Given the location of the project, the analysis focuses on the jurisdiction over water and wetlands and takes into consideration the Clean Water Act (CWA) and its State iterations (in California the Porter-Cologne Act), the River and Harbors Act, Section 1602 of the California Fish and Game Code, and Section 30121 of the California Coastal Act.

Section 404 of the CWA covers waters of the United States (WoUS) as well as federal wetlands. Section 10 of the Rivers and Harbors Act covers navigable waters and rivers. Both Section 404 and Section 10 establish the jurisdiction by the U.S. Army Corps of Engineers (USACE). The Regional Water Quality Control Board (RWQCB), under guidance from the U.S. Environmental Protection Agency (EPA), regulates at the state level all activities that are regulated at the federal level by USACE through CWA Section 401. The RWQCB/State Water Resources Control Board (SWRCB) may also regulate activities that affect non-federal waters and wetlands (e.g., isolated features) under the Porter-Cologne Act. Section 1600 et. seq. of the California Fish and Game Code is regulated by the California Department of Fish and Wildlife (CDFW) and covers aquatic features, which may include lakes or streambeds or other aquatic features that support wildlife or potential habitat for wildlife. Section 30121 of the California Coastal Act establishes the jurisdiction by the California Coastal Commission (CCC), which regulates all development activities in the Coastal Zone, including wetlands, as defined by the CCC under Title 14 of the California Code of Regulations, and Environmentally Sensitive Habitat Areas (ESHAs), defined under Section 30107.5 of the California Coastal Act. If a proposed project may affect waters or wetlands, the project site must be evaluated to determine the presence of jurisdictional waters. Permits for the proposed activity must be sought from each applicable resource agency. Details regarding each of these resource agencies and their regulatory authority, jurisdiction, permits, and regulatory processes are provided in Chapter 2, *Regulatory Background*.

The information and results presented herein document the investigation, best professional judgment, and conclusions of the investigators. It is correct and complete to the best of our knowledge. However, all jurisdictional determinations should be considered preliminary until reviewed and approved by the regulatory agencies.

1.1 Project Location

The proposed project is located at the northeast corner of Hurricane Street and Canal Court across and immediately north of the existing Venice Pumping Plant (Figure 1). The project would be located on two three existing vacant lots (Assessor Parcel Numbers [APN]: 4225-008-904 and 42250089044225-010-016), which are owned by the City of Los Angeles, two of which would serve

as laydown areas. Laydown Area 1 would be used for soil stockpile and construction materials and equipment and then permanently converted to parking and open space once the proposed project is operational. Laydown Area 2, located on the east side of the Grand Canal would be used for temporary storage of construction material and equipment, and two laydown areas, as well as within the Grand Canal. The site is mapped in Township 2 South, Range 15 West, Section 21 U.S. Geological Survey (USGS) 7.5-minute "Venice" quadrangle map (USGS 1964) (Figure 2).

1.2 Project Description

The project would include the construction of an auxiliary pumping facility that would provide additional reliability and supplement capacity to the existing Venice Pumping Plant (VPP). The project would be sized to supplement the pumping capacity of the VPP (Pump Station No. 646), for a combined ultimate peak flow capacity of 87 million gallons per day (mgd), reflecting wet weather flows of a 10-year storm event. Major project components of the VAPP would include: one electrical building approximately 3532-feet in height, three pumps constructed below ground level, utility connections, transformers and generators, 17-feet by 17-feet submerged diversion structure, the top of which will be below the channel bed, or the lowest elevation of the Grand Canal, and a 66-inch sewer to connect VAPP to the new diversion structure. A portion of Hurricane Street between and Canal Court and Esplanade would be temporarily closed off during construction and then reopened , with Hurricane Street from Canal Court to Esplanade closed to the public once the facility is operational. Shoring would be installed around the project site, and then excavation would occur to a depth of approximately 25 feet. The proposed project would require the excavation of approximately 10,000 cubic yards of soil of which approximately 2,300 cubic yards would be stockpiled at Laydown Area 1. The remaining 7,700 cubic yards of soil would be exported off-site and stockpiled at Laydown Area 3 in Culver Cityexported off-site and disposed of in an approved area landfill. Laydown Area 2 (across Grand Canal), given the slope and access constraints, may be used only as needed for equipment and materials storage. Water pumped from the site would be disposed of in a manner consistent with Regional Water Quality Control Board (RWQCB) regulations. Construction of the underground facilities associated with the VAPP, including the three new pumps, the wet well, valve vault, meter vault and piping, would occur. These facilities would be constructed at a maximum depth of approximately 25 feet below ground. Within the Grand Canal, a diversion structure approximately 23-feet by 95-feet would be excavated to a depth of approximately 18 feet below ground and then sealed. Excavated materials would be hauled from the site and stockpiled at either Laydown Area 1 or Laydown Area 3 or transported to an approved area landfill; upon completing of installation and sealing, The Grand Canal would be backfilled using the stockpiled excavated material and the coffer dam removed.Excavated materials would be hauled from the site and disposed of at an appropriate location. Water flowing in the Grand Canal would be diverted around a cofferdam structure by the presence of the dam itself. The diversion structure would then be constructed around the in-service Coastal Interceptor Sewer (CIS) pipe. Construction of the cofferdam, placement of the diversion structure, and backfill and soil compaction within the Grand Canal would last approximately three months. The CIS pipe would be cut so that the modular insert could be installed. The pipes would then be connected and a seal would be inserted into the shell. Backfill and soil compaction would be completed, and the Grand Canal channel bottom would be restored to its original elevation. Finally, the diversion structure will be sealed, removing all shoring steel, and allowing flows to resume to pre-construction conditions within the Grand Canal. The Esplanade would be re-opened to pedestrian access on the west side of the Grand Canal. Surface

improvements at the site will occur, consisting of constructing an approximately 3532-foot high electrical building and installing two new 480-Volt City of Los Angeles Department of Water and Power transformers.

Chapter 2
Regulatory Background

The following sections summarize the regulations imposed on each type of jurisdictional feature potentially present within the study area.

2.1 Waters and Activities Regulated by U.S. Army Corps of Engineers

USACE regulates the discharge (temporary or permanent) of dredged or fill material into WoUS, including wetlands. A discharge of fill material includes, but is not limited to, grading, placing riprap for erosion control, pouring concrete, and stockpiling excavated material into WoUS.[1]

2.1.1 Waters of the United States

WoUS within the study area may include some or all of the following classifications of potentially jurisdictional aquatic resources. WoUS, as defined in Code of Federal Regulations (CFR) Title 33, Section 328.3, includes:

(1) All waters that are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters that are subject to the ebb and flow of the tide;

(2) All interstate waters, including interstate wetlands;

(3) All other waters, such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation, or destruction of which could affect interstate or foreign commerce, including any such waters:

(i) That are or could be used by interstate or foreign travelers for recreational or other purposes; or

(ii) From which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or

(iii) That are used or could be used for industrial purpose by industries in interstate commerce;

(4) All impoundments of waters otherwise defined as waters of the United States under the definition;

(5) Tributaries of waters identified in paragraphs (1) through (4) of this section;

(6) The territorial seas;

(7) Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (1) through (6) of this section.

(8) Waters of the United States do not include prior converted cropland. Notwithstanding the determination of an area's status as prior converted cropland by any other federal agency, for

[1] Activities that generally do not involve a regulated discharge (if performed specifically in a manner to avoid discharges) include driving pilings, performing certain drainage channel maintenance activities, constructing temporary mining and farm/forest roads, and excavating without stockpiling.

> the purposes of the Clean Water Act, the final authority regarding Clean Water Act jurisdiction remains with EPA.
>
> Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA (other than cooling ponds as defined in 40 CFR 423.11(m), which also meet the criteria of this definition), are not waters of the United States.

Excluding wetlands and tidal waters, the limit of USACE jurisdiction is delineated using the ordinary high-water mark (OHWM), defined in CFR 328.3(e) as:

> …that line on the shore established by the fluctuations of water and indicated by physical characteristics such as [a] clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas.

The limit of Section 404 jurisdiction within navigable/tidal waters is delineated using the maximum predicted annual tide (or High-Tide Level [HTL]) for the previous year. The HTL elevations for each tidal gauge station are available online from the National Oceanic and Atmospheric Administration (NOAA) (NOAA 2015a).

2.1.2 Special Aquatic Sites and Wetlands

Section 404 of the CWA identifies six categories of Special Aquatic Sites: Sanctuaries and Refuges, Wetlands, Mudflats, Vegetated Shallows, Coral Reefs, and Riffle and Pool Complexes. Wetlands are explained in detail below.

Normally, three criteria must be satisfied to classify an area as a jurisdictional wetland: (1) a predominance of plant life that is adapted to life in wet conditions (hydrophytic vegetation); (2) soils that saturate, flood, or pond long enough during the growing season to develop anaerobic conditions in the upper part (hydric soils); and (3) permanent or periodic inundation or soils saturation, at least seasonally (wetland hydrology) (Environmental Laboratory 1987).

2011 Draft Clean Water Act Guidance

On April 27, 2011, USACE and EPA issued draft guidance for determining jurisdiction under the CWA (USACE 2011). The guidance supersedes the previous guidance from 2003 regarding *SWANCC* (68 *Federal Register* 1991–1995) and 2007 *Rapanos* guidance. This document reiterated the guidance issued under the *Rapanos* decision, asserting that the following waters are protected by the CWA.

- Traditional navigable waters
- Interstate waters
- Wetlands adjacent to either TNWs or interstate waters
- Non-navigable tributaries to TNWs that are relatively permanent (meaning they contain water at least seasonally)
- Wetlands that directly abut relatively permanent waters

The guidance further clarifies the criteria for defining TNWs, primarily consistent with previous guidance. In addition, a significant nexus evaluation is required for the "other waters" category of the regulations (see item 3 in Section 2.1.1, *Waters of the United States*, above). The guidance divides these waters into two categories—those that are physically proximate to other jurisdictional waters and those that are not—and discusses how each category should be evaluated.

Finally, the guidance reiterated that certain aquatic areas are generally not considered WoUS, as follows.

- Wet areas that are not tributaries or open waters and do not meet the agencies' regulatory definition of "wetlands"
- Waters that are excluded from coverage under the CWA by existing regulations
- Waters that lack a "significant nexus" where one is required for a water to be protected by the CWA
- Artificially irrigated areas that would revert to upland should irrigation cease
- Artificial lakes or ponds created by excavating and/or diking dry land and used exclusively for such purposes as stock watering, irrigation, settling basins, or rice growing
- Artificial reflecting pools or swimming pools created by excavating and/or diking dry land
- Small ornamental waters created by excavating and/or diking dry land for primarily aesthetic reasons
- Water-filled depressions created incidental to construction activity
- Groundwater drained through subsurface drainage systems
- Erosional features (gullies and rills) and swales and ditches that are not tributaries or wetlands

2.1.3 Section 10 of the Rivers and Harbors Act

Section 10 of the Rivers and Harbors Act gives USACE regulatory and permitting authority over work in, over, or under "navigable WoUS." Regulated Section 10 activities include the construction of structures in or over navigable WoUS, the excavation/dredging or deposition of material in navigable WoUS, or any obstruction or alteration to a navigable WoUS. Section 10 navigable WoUS and Section 404 WoUS do overlap in some areas that involve wetlands and non-wetland waters associated with navigable WoUS.

The limits of Section 10 navigable WoUS are defined by the Mean High Water (MHW) elevation, using Mean Lower Low Water (MLLW) as a baseline (MHW minus MLLW = Section 10 MHW).

2.2 Waters and Activities Regulated by the State of California

2.2.1 Section 401 of the Clean Water Act

Before USACE will issue a Section 404 permit, applicants must apply for and receive a Section 401 water quality certification or waiver. Under Section 401 of the CWA, all activities that are regulated at the federal level by USACE are also regulated at the state level. Therefore, state jurisdiction usually includes all waters or tributaries to waters that are determined to be WoUS and, similar to WoUS, typically delineated at the OHWM. However, if it is determined that the waters are not WoUS,

they may still be subject to state jurisdiction based on the Porter-Cologne Act. Pursuant to Section 401 of the CWA:

> …any applicant for a federal permit for activities that involve a discharge to waters of the United States shall provide the federal permitting agency a certification from the state in which the discharge is proposed that states that the discharge will comply with the applicable provisions under the federal Clean Water Act.

2.2.2 Porter-Cologne Water Quality Control Act

In addition to the USACE, the state also regulates activities that would involve "discharging waste, or proposing to discharge waste, within any region that could affect waters of the State" (California Water Code 13260(a)),. The definition of WoS in California is wider than the the definition of WoUS included in Section 404 of the CWA. Waters of the State (WoS) are defined as "any surface water or groundwater, including saline waters, within the boundaries of the state" (California Water Code 13050(e)).. These waters may include isolated vernal pools, isolated wetlands, or other aquatic habitats that are not normally subject to federal regulation under Section 404 of the CWA.

2.2.3 Jurisdiction of the State Water Resources Control Board/Regional Water Quality Control Boards

In California, SWRCB and nine RWQCBs regulate activities within state and federal waters under Section 401 of the CWA and the Porter-Cologne Act. SWRCB is responsible for setting statewide policy, coordinating and supporting RWQCB efforts, and reviewing petitions that contest RWQCB actions. Each semi-autonomous RWQCB sets water quality standards, issues Section 401 certifications and waste discharge requirements, and takes enforcement action for projects that occur within its boundary. However, when a project crosses multiple RWQCB jurisdictional boundaries, SWRCB becomes the regulating agency and issues project permits.

2.3 Activities Regulated by the California Department of Fish and Wildlife Regulated

Pursuant to Sections 1600–1616 of the California Fish and Game Code, CDFW regulates any activity that will substantially divert or obstruct the natural flow—or substantially change or use any material from the bed, channel, or bank—of any river, stream, or lake. CDFW also regulates any activity that will deposit or dispose of debris, wastewater, or other material containing crumbled, flaked, or ground pavement that may pass into any river, stream, or lake. The applicant must notify CDFW prior to such activities and obtain a Lake or Streambed Alteration Agreement.

2.3.1 California Department of Fish and Wildlife Jurisdiction

CDFW jurisdiction includes ephemeral, intermittent, and perennial watercourses (including dry washes) and lakes that are characterized by the presence of (1) definable bed and banks and (2) existing fish or wildlife resources. Furthermore, CDFW jurisdiction often extends to habitats adjacent to watercourses, such as oak woodlands in canyon bottoms or willow woodlands that

support hydrologic functions within the riparian system. CDFW jurisdiction typically does not include features without a discernible bed and bank, such as swales, vernal pools, or wet meadows.

2.4 California Coastal Act – California Coastal Commission

In 1972, the United States Congress passed the Coastal Zone Management Act (CZMA) (Title 16 United States Code 1451–1464). The CZMA declared a national policy "to preserve, protect, develop, and, where possible, restore or enhance the resources of the nation's Coastal Zone for this and succeeding generations" and sought to encourage and help states develop and implement management programs for the use of coastal land and water resources, "giving full consideration to ecological, cultural, historic, and esthetic values as well as the need for compatible economic development."

To achieve maximum responsiveness to local conditions, accountability, and public accessibility, the California Coastal Act relies heavily on local government and local land use planning procedures and enforcement. Therefore, implementation of California Coastal Act policies is accomplished primarily through the preparation of Local Coastal Programs (LCPs), which are reviewed and approved by the CCC. The project occurs within the Venice LCP, which was certified in 2001. Therefore, the project is subject to the Venice LCP policy with ultimate approval from the CCC.

An LCP typically consists of a Land Use Plan (LUP) and an Land Implementation Plan (LIP). The LUP indicates the kinds, locations, and intensities of land uses; the applicable resource protection and development policies; and, where necessary, a listing of implementing actions. The LIP consists of the zoning ordinances, zoning district maps, and other legal instruments that are necessary to implement the LUP. Any amendments to the certified LCP will require review and approval by the CCC prior to becoming effective. After certification of an LCP, coastal development permit authority is delegated to the appropriate local government. The CCC retains original permit jurisdiction over certain specified lands, such as submerged lands, tidelands, and public trust lands, and has appellate authority over development approved by local government in specified geographic areas and for major public works projects and major energy facilities.

In authorizing coastal development permits, the local government must find that the development conforms to the certified LCP. Furthermore, after certification of the LCP, city actions on applications for California Coastal Act authority to conduct certain types of development, as well as development within certain geographic areas, are appealable to the CCC.

2.4.1 Definition of Wetlands and Policy

Section 30121 of The California Coastal Act defines wetlands as such:

> Wetland "means lands within the Coastal Zone may be covered periodically or permanently with shallow water and include saltwater marshes, freshwater marshes, open or closed brackish water marshes, swamps, mudflats, and fens."

The CCC applies a one-parameter approach to defining wetlands. As such, any area with a preponderance of hydrophytic vegetation, the presence of hydric soils, or wetland hydrology meets

the definition of a wetland in the Coastal Zone. This is important to the site because many areas meet the one-parameter wetland definition.

Section 13577(b) of Title 14, Division 5.5, Article 18, of The California Code of Regulations defines wetlands as such:

(1) Measured 100 feet landward from the upland limit of the wetland. Wetland shall be defined as land where the water table is at, near, or above the land surface long enough to promote the formation of hydric soils or to support the growth of hydrophytes and shall also include those types of wetlands where vegetation is lacking and soil is poorly developed or absent as a result of frequent and drastic fluctuations of surface water levels, wave action, water flow, turbidity, or high concentrations of salts or other substances in the substrate. Such wetlands can be recognized by the presence of surface water or saturated substrate at some time during each year and their location within, or adjacent to, vegetated wetlands or deep-water habitats. For purposes of this section, the upland limit of a wetland shall be defined as:

   (A) The boundary between land with predominantly hydrophytic cover and land with predominantly mesophytic or xerophytic cover;

   (B) The boundary between soil that is predominantly hydric and soil that is predominantly non-hydric; or

   (C) In the case of wetlands without vegetation or soils, the boundary between land that is flooded or saturated at some time during years of normal precipitation and land that is not.

(2) For the purposes of this section, the term "wetland" shall not include wetland habitat created by the presence of and associated with agricultural ponds and reservoirs where:

   (A) The pond or reservoir was in fact constructed by a farmer or rancher for agricultural purposes; and

   (B) There is no evidence (e.g., aerial photographs, historical survey, etc.) showing that wetland habitat pre-dated the existence of the pond or reservoir. Areas with drained hydric soils that are no longer capable of supporting hydrophytes shall not be considered wetlands.

2.4.2 Environmentally Sensitive Habitat Areas

The California Coastal Act (California Public Resources Code Division 20, Section 30240a) restricts land uses within or adjacent to ESHAs. The California Coastal Act, Section 30107.5, defines an ESHA as:

> …any area in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and could be easily disturbed or degraded by human activities and developments.

Included within this definition are wetlands, estuaries, streams, riparian habitats, lakes, and portions of open coastal waters that meet the rare or valuable habitat criteria. Not all wetlands necessarily meet the "rare or valuable habitat criteria," and as set forth in Section 30233, "where there is no feasible less environmentally damaging alternative and where feasible mitigation measures have been provided to minimize adverse environmental effects," degraded or low-value wetlands that do not meet the rare or valuable habitat criteria may be subject to restoration in accordance with Section 30233.7.

Chapter 3
Methodology

3.1 Project Research

Project research was conducted to determine the areas over which different Federal and State agencies have jurisdiction and authorization power. Prior to the field visit, a 200-foot-scale (1 inch = 200 feet) aerial photograph of the study area was obtained and compared with USGS 7.5-minute topographic quadrangles to identify potential differing agency jurisdiction and jurisdictional features within the study area as indicated by vegetation types, topographic changes, or visible drainage patterns. The National Hydrography Dataset (NHD) data for the study area (USGS 2015) and the National Wetlands Inventory (USFWS 2015) were referenced to identify any mapped features such as streams and wetlands. The study area was carefully reviewed in Google Earth (Google Earth 2015) at various scales, and potential jurisdictional features were noted and identified on field maps. A review of the U.S. Department of Agriculture, Natural Resources Conservation Service, Soil Survey Geographic database (USDA/NRCS 2015) was attempted but no soil data is available for the study area.

3.2 Jurisdictional Delineation

ICF biologists Paul Schwartz and Lily Sam conducted the jurisdictional waters and wetland delineation for the study area on September 21, 2015. The jurisdictional delineation was conducted between 9:00 a.m. and 1 p.m. The tide during the September 21 field visit was rising from a low tide of +3.02 feet mean sea level (msl) at 9:10 a.m. to a high tide of 4.65 feet msl at 3:51 p.m. (NOAA 2015a). Weather conditions during the delineation consisted of clear skies (5–15% cloud cover), temperatures ranging from 81–88 degrees Fahrenheit, with winds ranging from 0–2 miles per hour. The study area was surveyed on foot and jurisdictional limits, wetland sample points, culverts, and other notable locations were recorded using a Trimble Yuma global positioning system (GPS) unit with a Geneq SX Blue II receiver, providing sub-meter accuracy, and recorded on field maps. Common plant species observed were identified by visual characteristics and morphology in the field. Taxonomic nomenclature for plants follows the National Wetlands Plant List (USACE 2014). If plants were unknown, the *Jepson Manual: Vascular Plants of California,* second edition (Baldwin et al. 2012), was used to identify plants to species level.

On September 29, 2015, Arcadis U.S. Inc. conducted a topographic mapping of a subset of the study area (Appendix A, Figures 6a and 6b). The topographic mapping was prepared at 0.5-foot intervals using National Geodetic Vertical Datum of 1929 (NGVD 29). The NGVD 29 elevations were then converted to North American Vertical Datum of 1988 (NAVD 88) elevations using an Orthometric Height Conversion calculator available via North American Vertical Datum Conversion (VERTCON) (NOAA 2015b). The NOAA MHW and HTL elevations (MLLW datum) were then adjusted to match the NAVD 88 topographic elevations depicted on Figure 6a and 6b by subtracting 0.19 foot from each elevation.

3.2.1 U.S. Army Corps of Engineers Jurisdiction

In order to accurately map the limits of USACE jurisdictional waters and wetlands within the study area, the jurisdictional delineation consisted of two components: a field visit and a desktop analysis. The methodology for both of these components is discussed below.

USACE Field Investigation

Potential Section 404 WoUS and wetlands were initially delineated using methods established in the *Wetland Delineation Manual* (Environmental Laboratory 1987), the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (USACE 2008a), *A Field Guide to the Identification of the Ordinary High-Water Mark (OHWM) in the Arid West Region of the Western United States* (USACE 2008b), and 2007 and 2008 *Rapanos* guidance (USACE and EPA 2008).[2]

During the September 21, 2015 field visit, the delineation of non-wetland waters was based on the presence of observable OHWM indicators, consisting of break in bank slope, debris wracking, staining, change in sediment texture, and change in vegetation cover. Paired wetland sample points were spaced throughout the study area to determine the limits of the USACE wetland boundary.

At each wetland sample point, several parameters were considered to determine whether the sample point was within a wetland. Three criteria normally must be fulfilled to classify an area as a jurisdictional USACE wetland: (1) a predominance of hydrophytic vegetation, (2) the presence of hydric soils, and (3) the presence of wetland hydrology. Details regarding the application of these techniques are described below.

- **Hydrophytic Vegetation:** The hydrophytic vegetation criterion is satisfied at a location if greater than 50 percent of all the dominant species present within the vegetation unit have a wetland indicator status of obligate (OBL), facultative wetland (FACW), or facultative (FAC) (Environmental Laboratory 1987). An OBL indicator status refers to plants that have a 99 percent probability of occurring in wetlands under natural conditions. An FACW indicator status refers to plants that usually occur in wetlands (67–99 percent probability) but are occasionally found elsewhere. An FAC indicator status refers to plants that are equally likely to occur in wetlands or elsewhere (estimated probability 34–66 percent for each). An NI (no indicator) status designates that insufficient information was available to determine an indicator status. An NO (no occurrence) status indicates that the species does not occur in the region. When a plant with an NO status is found within a region, it usually indicates that the plant is ornamental. The wetland indicator status used for this report follows the *Arid West 2014 Regional Wetland Plant List* (USACE 2014).
- **Hydric Soils:** The definition of a hydric soil is a soil that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper part (USDA/NRCS 1994). This determination is based on the various field indicators detailed in the *Arid West Supplement* and the *Field Indicators of Hydric Soils in the United States* (Version 7.0) (USDA/NRCS 2010).

[2] On June 5, 2007, USACE and EPA issued guidance related to the *Rapanos-Carabell* consolidated decisions to address the question of jurisdiction over attenuated tributaries to WoUS as well as wetlands adjacent to those tributaries. On December 2, 2008, USACE and EPA issued guidance that incorporated revisions to the June 5, 2007, memorandum. The *Rapanos-Carabell* decision is discussed in further detail in Section 2.1.4, above.

- **Wetland Hydrology:** Wetland hydrology is determined using indicators of inundation or saturation (flooding, ponding, or tidally influenced) detailed in the *Wetland Delineation Manual* and the *Arid West Supplement*.

USACE Desktop Analysis

On November 3, 2015, USACE Regulatory Section Chief Dan Swenson was contacted to confirm the appropriate delineation approach for the study area[3]. Due to the tidal influence in the study area, it was determined that Section 404 waters of the U.S. and wetlands as well as Section 10 navigable waters would need to be delineated. Section 404 tidal waters[4] and Section 10 navigable waters are mapped using elevations based on NOAA tidal stations. The tidal data from the Santa Monica Tidal Station (Station 9410840) were used to determine the elevational limits of Section 404 and Section 10 waters (NOAA 2015a).

Pursuant to USACE, guidance for delineating Section 404 tidal waters states that the upper elevational limit of Section 404 tidal waters is established based on the HTL. NOAA tidal stations do not provide HTL data, so the upper elevational limit of Section 404 waters is based on the maximum predicted annual tide for the given year (i.e., the highest tide predicted for the year) The maximum predicted annual tide for the Santa Monica Tidal Gauge Station for the study area is +6.9 feet msl (MLLW datum).

Pursuant to USACE, guidance for delineating Section 10 navigable waters states that the upper elevational limit of Section 10 waters is established based on the MHW elevation (+7.13 feet msl) and then adjusted to convert the tidal station datum to MLLW datum[5]. As such, the MLLW elevation (+2.44 feet msl) is subtracted from the MHW elevation in order to map Section 10 tidal waters (i.e., +7.13 feet msl minus +2.44 feet msl = +4.69 feet msl). Therefore, the upper elevational limit of Section 10 jurisdiction in the study area is +4.69 feet msl (MLLW datum).

Because the project topographic mapping provided was based on NAVD88 datum, the MHW and HTL elevations (MLLW datum) were then adjusted to match the NAVD 88 datum topographic elevations depicted on Figure 6a and 6b by subtracting 0.19 foot from each elevation. Therefore, the Section 404 elevation mapped in the study area is 6.71 feet (NAVD 88) and the Section 10 elevation mapped in the study area is 4.5 feet (NAVD 88).

3.2.2 Regional Water Quality Control Board Jurisdiction

The evaluation of state jurisdiction followed guidance from Section 401 of the CWA and typically follows the same jurisdictional areas that are used to define the limits of Section 404 WoUS and wetlands.

[3] Dan Swenson, USACE Regulatory Section Chief (Los Angeles District), personal communication, November 3, 2015

[4] Delineation procedures for Section 404 wetlands follows guidance outlined in *Wetland Delineation Manual* (Environmental Laboratory 1987), and the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region* (USACE 2008a),

[5] NOAA Tidal datums are referenced to an station datum other than MLLW. In order to use NOAA station datums for surveying, the station datum must be reduced to MLLW, which is the standard reference datum for tide predictions, bench mark publications and nautical charting.

3.2.3 California Department of Fish and Wildlife Jurisdiction

CDFW jurisdiction typically includes features with a defined bed and bank. The evaluation of potential jurisdictional areas follows the guidance of relevant CDFW materials and standard practices by CDFW personnel. CDFW jurisdiction is generally delineated by measuring the outer width and length boundaries of potential jurisdictional areas, consisting of the greater of either the top-of-bank measurement or the extent of associated riparian or wetland vegetation.

For this project, in addition to delineating the physical limits of what could be considered limits of CDFW jurisdiction, the feature was also evaluated using satellite aerial photos (Google Earth 2015) to assess the inputs into the feature and its historical function as a marine non-aquatic resource. Based on the review of that data, it was determined that the feature is a canal/lagoon and primarily marine with minimal freshwater input, mostly from local runoff, and does not meet the CFGC definition of a lake or stream.

3.2.4 California Coastal Commission

CCC jurisdictional wetlands were mapped as the limits of one-parameter wetlands, consisting of the presence of a preponderance of hydrophytic vegetation, and/or the presence of hydric soils, and/or the presence of wetland hydrology. USACE standard definitions provided above were used to define each of the three potential wetland indicators used to delineate CCC wetlands. The upper limits of CCC one-parameter wetlands consisted of the greater of either the limits of the OHWM, Section 404 elevations, limits of hydric soils, or the upper limits of areas supporting a preponderance of hydrophytic vegetation.

Chapter 4
Environmental Setting

This chapter describes the topography, land use, hydrology, vegetation characteristics, and soils associated with the study area.

4.1 Topography and Land Use

The study area is within the coastal low lands of the community of Venice, City of Los Angeles, California, at the confluence of the Grand Canal and Ballona Lagoon. Ballona Lagoon is connected to the Marina Del Rey Harbor channel approximately 0.80 mile to the southeast, and the study area is subject to muted daily tidal fluctuations. The Grand Canal is the main channel of the Venice Canals. The elevations within the study area range from sea level to approximately 12 feet above mean sea level (msl) (USGS 1964). The study area consists primarily of either open water, the vegetated banks associated with Ballona Lagoon and the Grand Canal, or developed lands associated with the adjacent upland residential areas. A portion of the existing VPP is in the study area. Sidewalks run along both sides of the Grand Canal; however, the sidewalk on the eastern bank is in need of repair and has areas of pickleweed vegetation growing through cracks. The study area is surrounded by residential housing to the north, west and east, the existing VPP to the west, and open water associated with the Ballona Lagoon to the south.

The NHD depicts the Grand Canal and Ballona Lagoon within the study area as an NHD Streamline (Appendix A, Figure 3). The National Wetlands Inventory has mapped the following wetland types as occurring in the study area: Estuarine and Marine Deepwater and Estuarine and Marine Wetland occurring in Ballona Lagoon, and Riverine occurring in the Grand Canal (Appendix A, Figure 4).

4.1.1 Hydrologic Unit

The study area is within the Garapito Creek-Frontal Santa Monica Bay Hydrologic Unit Code (HUC) 10 watershed, which is included in the larger Santa Monica Bay HUC 8 watershed. The Garapito Creek-Frontal Santa Monica Bay HUC 10 and Santa Monica Bay HUC 8 watersheds terminate in the Pacific Ocean (Appendix A, Figure 5).

The Santa Monica Bay HUC 8 watershed drains an area of approximately 385 square miles and contains 27 sub-watersheds. The northern extent of the watershed extends along the Ventura-Los Angeles County line on the west to the Ballona Creek Watershed to the south. Much of the northern portion of the watershed is open space associated with the Santa Monica Mountains. The middle and southern portions of the watershed are more urban and contains portions of Los Angeles, Santa Monica, El Segundo, Manhattan Beach, Redondo Beach and Palos Verdes. (City of Los Angeles Stormwater Program 2015.)

Chapter 5
Jurisdictional Delineation Results

This chapter describes the delineated features and expected jurisdictional status within the study area. This report documents the potential jurisdictional waters, wetlands, and other aquatic features within the study area. An impacts analysis is not included as a part of this report.

The information and results included herein document the investigation, best professional judgment, and conclusions of the investigators. It is correct and complete to the best of our knowledge. However, all jurisdictional determinations should be considered preliminary until reviewed and approved by the regulatory agencies. The study area was delineated with the understanding that a request for a Preliminary JD would be submitted for the project.

Appendix A, Figures 6a and 6b, depict the results of the jurisdictional delineation. Photographs documenting the conditions present during the delineation are provided in Appendix B. Wetland Determination Data forms are provided in Appendix C, and a Preliminary JD form is included in Appendix D.

5.1 Delineated Feature Descriptions

Two named features depicted on the Venice USGS topographic quadrangle map containing the study area were documented as occurring within the study area: Ballona Lagoon and Grand Canal. For the purposes of this delineation, the two features are treated as one feature of open water and associated wetlands referred to as Ballona Lagoon and Grand Canal. The feature was determined to contain waters and wetlands subject to the jurisdiction of USACE under Section 404 and Section 10 of the CWA, waters and wetlands subject to the jurisdiction of the RWQCB under Section 401 of the CWA, and coastal wetlands subject to the jurisdiction of CCC under Title 14 of the California Code of Regulations and Section 30107.5 of the California Coastal Act. Each of the various jurisdictions is discussed below. Table 5-1 presents a summary of all jurisdictions within the study area.

5.1.1 USACE/RWQCB Jurisdiction Description

Within the study area, the Ballona Lagoon and the Grand Canal is a perennial water feature and is a direct tributary to the Marina Del Rey Harbor Channel and the Pacific Ocean. Based on physical evidence (i.e., break in bank slope, debris wracking, staining, change in sediment texture, and change in vegetation cover) within the study area, the OHWM was observed to be at the toe of the slope along the 2.5-foot elevational contour. Based on the tidal gauge data from the Santa Monica Tidal Gauge Station (adjusted to plot on NAVD 88 topographic elevations), the limits of potential Section 404 and Section 10 waters were determined to be +6.71 feet (NAVD 88) and +4.5 feet (NAVD 88), respectively (Appendix A, Figure 6a). Several sets of paired wetland sample points were assessed to determine the extent of three-parameter USACE wetlands. Based on the results of the wetland sample points, the lower areas of the channel banks were determined to meet the criteria for three-parameter USACE wetlands (Appendix A, Figure 6a).

Within the study area, approximately 0.929 acre of USACE Section 404 WoUS and 0.075 acre of Section 404 wetlands were delineated, and approximately 0.793 acre of Section 10 navigable waters was delineated.

Within the study area, approximately 0.929 acre of RWQCB Section 401 WoS and 0.075 acre of Section 401 wetlands were delineated. Appendix A, Figure 6a, depicts potential USACE and RWQCB jurisdiction delineated within the study area.

5.1.2 CDFW Jurisdiction Description

As discussed in Section 3.2.3 above, it was determined that this feature was not subject to CDFW jurisdiction, based on the lack of freshwater input and the historic context of this feature receiving any freshwater flows. It should be noted that the feature does provide habitat and so is expected to be subject to CDFW jurisdiction under the California Endangered Species Act (CESA) and the California Environmental Quality Act (CEQA). Those assessments and conclusions are discussed separately in the *Biological Resources and Habitat Assessment, Venice Auxiliary Pumping Plant, Los Angeles County, California*, dated January 2016 (ICF 2016).

5.1.3 CCC Jurisdiction Description

The limits of potential CCC jurisdictional one-parameter wetlands in the study area were determined by the presence of the hydrology parameter, which was based on the limits of Section 404 WoUS (6.71 feet, NAVD 88). The 6.71 foot msl elevation exceeded the limits of the hydric soil and hydrophytic vegetation parameters. Within the study area, approximately 0.929 acre of CCC jurisdiction was mapped. Appendix A, Figure 6b, depicts potential CCC jurisdiction mapped within the study area.

5.2 Delineation Results Summary

Within the entire study area, one feature that could be subject to the jurisdiction of USACE, RWQCB/EPA, CDFW, and CCC was delineated: Ballona Lagoon and Grand Canal. USACE and RWQCB/EPA potential jurisdictional areas within the study area total approximately 0.929 acre of Section 404 non-wetland WoUS/Section 401 non-wetland WoS and 0.075 acre of Section 404 wetland WoUS and Section 401 wetland WoS. Additionally, 0.793 acre of potential USACE Section 10 WoUS was mapped in the study area. Appendix A, Figure 6a, depicts the limits of potential USACE/RWQCB jurisdiction in the study area. Potential CCC jurisdiction within the study area totaled approximately 0.929 acre of one-parameter wetlands. Appendix A, Figure 6b, depicts the limits of potential CCC jurisdiction in the study area.

Table 5-1. Jurisdictional Delineation Summary (acres)

	Ballona Lagoon and Grand Canal	
Jurisdiction	**Acres**	**Total**
USACE Section 404 Non-Wetland WoUS/RWQCB Section 401 Non-Wetland WoS	0.929	0.929
USACE Section 404 Wetland WoUS/RWQCB Section 401 Wetland WoS	0.075	0.075
USACE Section 10 Navigable WoUS	0.793	0.793

CCC One-Parameter Wetlands	0.929	0.929

Location	Sidewalk on east side of Grand Canal.
Direction	Southeast
Comment	Photo depicts conditions present along the sidewalk on the east side of Grand Canal.

	**Photograph #** 13 **Photo Date** 9/21/2015 **Location** East side of the study area, confluence of Grand Canal and Ballona Lagoon. **Direction** Northwest **Comment** Photo depicts conditions present along the sidewalk on the east side of Grand Canal.
	**Photograph #** 14 **Photo Date** 9/21/2015 **Location** East side of study area, in empty lot. **Direction** Northwest **Comment** Photo depicts location of SP 5.
	**Photograph #** 15 **Photo Date** 9/21/2015 **Location** East side of study area, in empty lot. **Direction** Northwest **Comment** Photo depicts location of SP 6.

Appendix C
Wetland Determination Data Forms

WETLAND DETERMINATION DATA FORM – Arid West Region

Project/Site: Venice - APP City/County: Venice Beach Los Angeles Sampling Date: 9-21-15

Applicant/Owner: LABOE State: CA Sampling Point: 1

Investigator(s): Paul Schwartz / Lily Sam Section, Township, Range: No Section, T1SW R2S venice CA

Landform (hillslope, terrace, etc.): slope Local relief (concave, convex, none): Concave Slope (%): ~5

Subregion (LRR): C - Med Lat: 33.975980° Long: -118.460989 Datum: WGS 84

Soil Map Unit Name: No available soil data NWI classification: Estuarine / Marine Wetland

Are climatic / hydrologic conditions on the site typical for this time of year? Yes ✓ No ____ (If no, explain in Remarks.)

Are Vegetation ____, Soil ____, or Hydrology ____ significantly disturbed? No Are "Normal Circumstances" present? Yes ✓ No ____

Are Vegetation ____, Soil ____, or Hydrology ____ naturally problematic? No (If needed, explain any answers in Remarks.)

SUMMARY OF FINDINGS – Attach site map showing sampling point locations, transects, important features, etc.

Hydrophytic Vegetation Present?	Yes ✓ No ____	**Is the Sampled Area within a Wetland?** Yes ✓ No ____
Hydric Soil Present?	Yes ✓ No ____	
Wetland Hydrology Present?	Yes ✓ No ____	

Remarks:

VEGETATION – Use scientific names of plants.

OBL species	x 1 =	
FACW species	x 2 =	
FAC species	x 3 =	
FACU species	x 4 =	
UPL species	x 5 =	
Column Totals: (A)		(B)

Prevalence Index = B/A = ____

Hydrophytic Vegetation Indicators:

✓ Dominance Test is >50%

___ Prevalence Index is ≤3.0[1]

___ Morphological Adaptations[1] (Provide supporting data in Remarks or on a separate sheet)

___ Problematic Hydrophytic Vegetation[1] (Explain)

[1]Indicators of hydric soil and wetland hydrology must be present, unless disturbed or problematic.

Hydrophytic Vegetation Present? Yes ✓ No ____

Remarks:

SOIL

Sampling Point: 1

Profile Description: (Describe to the depth needed to document the indicator or confirm the absence of indicators.)

Depth (inches)	Matrix Color (moist)	%	Redox Features Color (moist)	%	Type[1]	Loc[2]	Texture	Remarks
0-14"	2.5Y 2.5/1	80	7.5YR 4/4	20	C	M	Sandy clay	

[1]Type: C=Concentration, D=Depletion, RM=Reduced Matrix, CS=Covered or Coated Sand Grains. [2]Location: PL=Pore Lining, M=Matrix.

Hydric Soil Indicators: (Applicable to all LRRs, unless otherwise noted.)

- ___ Histosol (A1)
- ___ Histic Epipedon (A2)
- ___ Black Histic (A3)
- ___ Hydrogen Sulfide (A4)
- ___ Stratified Layers (A5) (**LRR C**)
- ___ 1 cm Muck (A9) (**LRR D**)
- ___ Depleted Below Dark Surface (A11)
- ___ Thick Dark Surface (A12)
- ___ Sandy Mucky Mineral (S1)
- ___ Sandy Gleyed Matrix (S4)
- ___ Sandy Redox (S5)
- ___ Stripped Matrix (S6)
- ___ Loamy Mucky Mineral (F1)
- ___ Loamy Gleyed Matrix (F2)
- ___ Depleted Matrix (F3)
- X Redox Dark Surface (F6)
- ___ Depleted Dark Surface (F7)
- ___ Redox Depressions (F8)
- ___ Vernal Pools (F9)

Indicators for Problematic Hydric Soils[3]:

- ___ 1 cm Muck (A9) (**LRR C**)
- ___ 2 cm Muck (A10) (**LRR B**)
- ___ Reduced Vertic (F18)
- ___ Red Parent Material (TF2)
- ___ Other (Explain in Remarks)

[3]Indicators of hydrophytic vegetation and wetland hydrology must be present, unless disturbed or problematic.

Restrictive Layer (if present):

Type: None

Depth (inches): 0

Hydric Soil Present? Yes ✓ No ___

Remarks:

HYDROLOGY

Wetland Hydrology Indicators:

Primary Indicators (minimum of one required; check all that apply)

- ✓ Surface Water (A1)
- ___ High Water Table (A2)
- ___ Saturation (A3)
- ___ Water Marks (B1) (**Nonriverine**)
- ___ Sediment Deposits (B2) (**Nonriverine**)
- ___ Drift Deposits (B3) (**Nonriverine**)
- ___ Surface Soil Cracks (B6)
- ✓ Inundation Visible on Aerial Imagery (B7)
- ___ Water-Stained Leaves (B9)
- ___ Salt Crust (B11)
- ___ Biotic Crust (B12)
- ✓ Aquatic Invertebrates (B13)
- ___ Hydrogen Sulfide Odor (C1)
- ___ Oxidized Rhizospheres along Living Roots (C3)
- ___ Presence of Reduced Iron (C4)
- ___ Recent Iron Reduction in Tilled Soils (C6)
- ___ Thin Muck Surface (C7)
- ___ Other (Explain in Remarks)

Secondary Indicators (2 or more required)

- ___ Water Marks (B1) (**Riverine**)
- ___ Sediment Deposits (B2) (**Riverine**)
- ___ Drift Deposits (B3) (**Riverine**)
- ___ Drainage Patterns (B10)
- ___ Dry-Season Water Table (C2)
- ___ Crayfish Burrows (C8)
- ___ Saturation Visible on Aerial Imagery (C9)
- ___ Shallow Aquitard (D3)
- ___ FAC-Neutral Test (D5)

Field Observations:

Surface Water Present? Yes ✓ No ___ Depth (inches): 5"

Water Table Present? Yes ✓ No ___ Depth (inches): 5"

Saturation Present? (includes capillary fringe) Yes ___ No ✓ Depth (inches): ___

Wetland Hydrology Present? Yes ✓ No ___

Describe Recorded Data (stream gauge, monitoring well, aerial photos, previous inspections), if available:

Remarks: Mud snails present along and below OHWM

IMPORTANT NOTE: The information recorded on this form has not necessarily been verified by the Corps and should not be relied upon for later jurisdictional determinations.

Signature and Date of Regulatory Project Manager (REQUIRED)

Signature and Date of Person Requesting Preliminary JD (REQUIRED, unless obtaining the signature is impracticable)

EXPLANATION OF PRELIMINARY AND APPROVED JURISDICTIONAL DETERMINATIONS:

1. The Corps of Engineers believes that there may be jurisdictional waters of the United States on the subject site, and the permit applicant or other affected party who requested this preliminary JD is hereby advised of his or her option to request and obtain an approved jurisdictional determination (JD) for that site. Nevertheless, the permit applicant or other person who requested this preliminary JD has declined to exercise the option to obtain an approved JD in this instance and at this time.

2. In any circumstance where a permit applicant obtains an individual permit, or a Nationwide General Permit (NWP) or other general permit verification requiring "preconstruction notification" (PCN), or requests verification for a non-reporting NWP or other general permit, and the permit applicant has not requested an approved JD for the activity, the permit applicant is hereby made aware of the following: (1) the permit applicant has elected to seek a permit authorization based on a preliminary JD, which does not make an official determination of jurisdictional waters; (2) that the applicant has the option to request an approved JD before accepting the terms and conditions of the permit authorization, and that basing a permit authorization on an approved JD could possibly result in less compensatory mitigation being required or different special conditions; (3) that the applicant has the right to request an individual permit rather than accepting the terms and conditions of the NWP or other general permit authorization; (4) that the applicant can accept a permit authorization and thereby agree to comply with all the terms and conditions of that permit, including whatever mitigation requirements the Corps has determined to be necessary; (5) that undertaking any activity in reliance upon the subject permit authorization without requesting an approved JD constitutes the applicant's acceptance of the use of the preliminary JD, but that either form of JD will be processed as soon as is practicable; (6) accepting a permit authorization (e.g., signing a proffered individual permit) or undertaking any activity in reliance on any form of Corps permit authorization based on a preliminary JD constitutes agreement that all wetlands and other water bodies on the site affected in any way by that activity are jurisdictional waters of the United States, and precludes any challenge to such jurisdiction in any administrative or judicial compliance or enforcement action, or in any administrative appeal or in any Federal court; and (7) whether the applicant elects to use either an approved JD or a preliminary JD, that JD will be processed as soon as is practicable. Further, an approved JD, a proffered individual permit (and all terms and conditions contained therein), or individual permit denial can be administratively appealed pursuant to 33 C.F.R. Part 331, and that in any administrative appeal, jurisdictional issues can be raised (see 33 C.F.R. 331.5(a)(2)). If, during that administrative appeal, it becomes necessary to make an official determination whether CWA jurisdiction exists over a site, or to provide an official delineation of jurisdictional waters on the site, the Corps will provide an approved JD to accomplish that result, as soon as is practicable.

PRELIMINARY JURISDICTIONAL DETERMINATION FORM

This preliminary JD finds that there *"may be"* waters of the United States on the subject project site, and identifies all aquatic features on the site that could be affected by the proposed activity, based on the following information:

Appendix A - Sites

District Office: Los Angeles District | File/ORM #: | PJD Date:

State: CA | City/County: Los Angeles/Los Angeles County | Person Requestinq PJD:

Site Number	Latitude	Longitude	Cowardin Class	Est. Amount of Aquatic Resource in Review Area	Class of Aquatic Resource
1	33.975544	-118.461271	Estuarine	0.929	Non-Section 10 non-wetlanc
1	33.975544	-118.461271	Estuarine	0.075	Non-Section 10 wetland
1	33.975544	-118.461271	Estuarine	0.793	Section 10 tidal

Notes:

See attached jurisdictional delineation report for additional information.

Appendix E

Cultural Resources Screening Memorandum

MEMORANDUM

To: Gilberto Ruiz, ICF

From: Mark Robinson, ICF

Date: January 21, 2016

Re: Screening Memo-Venice Auxiliary Pumping Plant—Archaeology and Paleontology

---

For the Venice Auxiliary Pumping Plant Project (VAPP), archaeological and paleontological resources and human remains were evaluated with the following two considerations in mind: 1) known archaeological and paleontological resources that exist in the Project footprint; and 2) the potential to encompass as yet undiscovered archaeological and paleontological resources, as well as human remains within the project footprint and area of potential effect (APE).

Known Resources: To determine if archaeological resources—including prehistoric human remains--are known to be present in the Project area, ICF conducted a records search at the South Central Coastal Information Center (SCCIC) located at California State University Fullerton. SCCIC is a branch of the California Historical Resources Information Center, which maintains the State of California's official records of previously recorded cultural resource studies and recorded archaeological sites for Los Angeles County. The SCCIC records search included the project study areas of potential effect (APE) and a 0.5-mile buffer surrounding the APE.

The record search indicated that the VAPP site had been surveyed twice in the past, and that no prehistoric or historic archaeological resources or isolated artifacts were recorded in the current project's footprint or within the 0.5 mile surrounding record search area. (Two historic period cultural resources are within the 0.5-mile record search area--the Venice Canal Historic District Lan-19-167310 (HRI-021273), and the Warren Wilson Beach House, LAn-19-174098.)

An ICF International archaeologist also conducted a comprehensive archaeological pedestrian survey of the VAPP on August 20, 2015. This area was surveyed in order to inspect for and identify any previously undiscovered cultural resources. The pedestrian survey consisted of walking transects in an east/west orientation, spaced 3 meters apart. Ground surface visibility was fair with the surface somewhat obscured by vegetation resulting in approximately 80% surface visibility. No cultural resources were identified during the field survey. Based on the record search and survey, no archaeological resources are known to be present in the project footprint. No human remains are known to be present in the VAPP or surrounding area.

To determine if paleontological resources are known to be present in the Project footprint, ICF contacted the Natural History Museum of Los Angeles County (NHMLAC) and requested a search of

their vertebrate fossil resources records. NHMLAC responded on October 6, 2015, that they had no recorded fossil localities in the VAPP footprint or the surrounding area. Based on this locality records search, no paleontological resources are known to be present in the project footprint.

Potential for Undiscovered Resources: The Project area is on the western margin of the boundaries of Ballona Lagoon, a broad swampy marsh that existed in the area until 20th Century development. The geologic formation underlying the proposed project area is tentatively identified as clay and sand of existing marshlands. These sediments are Holocene in age, and are less than 10,000 years in age. Sediment in the Project area may also derived from beach dune sands deposited along the lee of the Pacific Ocean, which are also Holocene in age. Both of these sediments are too young to contain fossil resources.

This area was originally marshland and beach dunes adjacent to the outlet of Ballona Creek at the Pacific Ocean. This setting is unlikely to have preserved prehistoric archaeological resources, due to constant erosion and deposition, prior to modern development. These marshland and beach dune sediments have been substantially altered by 20th Century development. This development altered landforms in the VAPP and surroundings to enhance an existing drainage into the Venice Grand Canal, and to create level, above water level lots on both sides of the Canal, which includes the VAPP footprint. Canal dredge spoils appear to have been used as fill for this purpose, as well as imported fill materials.

Any grading and excavation for the project would occur within this mixture of sediment and fill, and would not encounter unique paleontological resources or geologic features. There is some potential to encounter significant archaeological resources in undisturbed sediments. These marshland and beach sediments are unlikely to be the setting for the discovery of prehistoric human remains.

Summary: Impacts to paleontological resources and human remains have been analyzed sufficiently in the Project Initial Study and will not be further evaluated in the Project EIR. CEQA mandated consultation with Native American groups will continue, as required by the new AB 52 legislation. This consultation will determine if any Tribal Cultural Resources (TCR) are present in the VAPP. This AB 52 consultation will be summarized in the EIR in the Cultural Resources chapter.

RE: Venice Auxilary Pumping Plant Project, Venice USGS Quadrangle, Los Angeles County

Dear Mr. Robinson:

Attached is a consultation list of tribes with traditional lands or cultural places located within the boundaries of the above referenced counties. Please note that the intent above reference codes is to mitigate impacts to tribal cultural resources, as defined, for California Environmental Quality Act (CEQA) projects.

As of July 1, 2015, Public Resources Code Sections 21080.1, 21080.3.1 and 21080.3.2 require public agencies to consult with California Native American tribes identified by the Native American Heritage Commission (NAHC) for the purpose mitigating impacts to tribal cultural resources:

> Within 14 days of determining that an application for a project is complete or a decision by a public agency to undertake a project, the lead agency shall provide formal notification to the designated contact of, or a tribal representative of, traditionally and culturally affiliated California Native American tribes that have requested notice, which shall be accomplished by means of at least one written notification that includes a brief description of the proposed project and its location, the lead agency contact information, and a notification that the California Native American tribe has 30 days to request consultation pursuant to this section. (Public Resources Code Section 21080.1(d))

The law does not preclude agencies from initiating consultation with the tribes that are culturally and traditionally affiliated with their jurisdictions. The NAHC believes that in fact that this is the best practice to ensure that tribes are consulted commensurate with the intent of the law.

In accordance with Public Resources Code Section 21080.1(d), formal notification must include a brief description of the proposed project and its location, the lead agency contact information, and a notification that the California Native American tribe has 30 days to request consultation. The NAHC believes that agencies should also include with their notification letters information regarding any cultural resources assessment that has been completed on the APE, such as:

1. The results of any record search that may have been conducted at an Information Center of the California Historical Resources Information System (CHRIS), including, but not limited to:

   - A listing of any and all known cultural resources have already been recorded on or adjacent to the APE;
   - Copies of any and all cultural resource records and study reports that may have been provided by the Information Center as part of the records search response;
   - If the probability is low, moderate, or high that cultural resources are located in the APE.
   - Whether the records search indicates a low, moderate or high probability that unrecorded cultural resources are located in the potential APE; and

- If a survey is recommended by the Information Center to determine whether previously unrecorded cultural resources are present.

2. The results of any archaeological inventory survey that was conducted, including:

   - Any report that may contain site forms, site significance, and suggested mitigation measurers.

     All information regarding site locations, Native American human remains, and associated funerary objects should be in a separate confidential addendum, and not be made available for pubic disclosure in accordance with Government Code Section 6254.10.

3. The results of any Sacred Lands File (SFL) check conducted through Native American Heritage Commission. There are a number of recorded archaeological sites in the area, including CA-LAN-63, 64, 65, 203, 204, and 206A. Please contact Mr. John Tommy Rosas of the Tongva Ancestral Territorial Tribal Nation for more information about this area. His email is tattnlaw@gmail.com and his telephone number is (310) 570-6567.

4. Any ethnographic studies conducted for any area including all or part of the potential APE; and

5. Any geotechnical reports regarding all or part of the potential APE.

Lead agencies should be aware that records maintained by the NAHC and CHRIS is not exhaustive, and a negative response to these searches does not preclude the existence of a cultural place. A tribe may be the only source of information regarding the existence of a tribal cultural resource.

This information will aid tribes in determining whether to request formal consultation. In the case that they do, having the information beforehand well help to facilitate the consultation process.

If you receive notification of change of addresses and phone numbers from tribes, please notify me. With your assistance we are able to assure that our consultation list contains current information.

If you have any questions, please contact me at my email address: rob.wood@nahc.ca.gov.

Sincerely,

Rob Wood

Subject: AB 52 Tribal Consultation: Venice Auxiliary Pumping Plant and Contact Corrections
To: jan.green.rebstock@lacity.org

Ms. Rebstock,

Thank you for the opportunity to comment on the above referenced project. As the project is outside of both boundaries on the traditional Tataviam territory map provided to the City of Los Angeles (attached), we do not wish to consult on VAPP.

Also, please note that the contact information provided to the City of Los Angeles on July 1st, 2015 lists the following as the AB 52 contact for Tataviam:

Caitlin B. Gulley
Tribal Historic and Cultural Preservation Officer
Fernandeño Tataviam Band of Mission Indians
1019 Second Street
San Fernando CA, 91340
Phone (818) 837-0794
Fax (818) 837-0796
cgulley@tataviam-nsn.us
If you would please forward this email or the discussion points of our map and contact information to the appropriate department for database correction, it would be greatly appreciated.

Thank you,

--

Los Angeles, CA 90015

RE: AB 52 Consultation; Proposed Venice Auxiliary Pumping Plant (VAPP) Project

The Soboba Band of Luiseño Indians has received your notification pursuant under Assembly Bill 52.

The Soboba Band of Luiseño Indians appreciates your observance of Tribal Cultural Resources and their preservation in your project. The information provided to us on said project(s) has been assessed through our Cultural Resource Department. At this time the Soboba Band does not have any specific concerns regarding known cultural resources in the specified areas that the project encompasses, but does request that the appropriate consultation continue to take place between concerned tribes, project proponents, and local agencies.

Also, working in and around traditional use areas intensifies the possibility of encountering cultural resources during any future construction/excavation phases that may take place. For this reason the Soboba Band of Luiseño Indians requests that approved Native American Monitor(s) be present during any future ground disturbing proceedings, including surveys and archaeological testing, associated with this project. The Soboba Band wishes to defer to Gabrieleño Tribal Consultants who are in closer proximity to the project. Please feel free to contact me with any additional questions or concerns.

Sincerely,

Joseph Ontiveros
Cultural Resource Director
Soboba Band of Luiseño Indians

> Dear Dr. Jan Green Rebstock
> As a direct Lineal Descendant of the Gabrieleño Kizh, I would like to acknowledge you & your agency that the above project location is within a highly sensitive area & in the village location of Suaangna . Previous developments in the area such as Playa Vista resulted in discoveries of human remains there fore During Ground Disturbance of this project location there is a high potential that there maybe human remains found . Therefore Our tribe would like to request one of our certified Native American Monitor to be on site during any and all ground disturbances to protect any cultural resources which may be effected during construction or development . We are there to work along side the developer and not against them .
>
> Avoid significant impacts…"
>
> In all cases, when the Native American Heritage Commission states there are "No Records of Sacred Sites" in the project area; the NAHC will always refer lead agencies to the respective Native American Tribe because the NAHC is only aware of general information and are not the "experts" on each California Tribe. Our Elder Committee & Tribal Historians are the experts for our Tribe and are able to provide a more complete history (both written and/or oral) regarding the location of historic villages, trade routes, cemeteries and sacred/religious sites in the project area. While the property may be located in an area that has been previously developed, numerous examples can be shared to show that there still is a possibility that unknown, yet significant, cultural resources will be encountered during ground disturbance activities. The recent implementation of AB52 dictates that lead agencies consult with Native American Tribes who can prove and document traditional and cultural affiliation with the area of said project in order to protect cultural resources. Our priorities are to avoid and protect without delay or conflicts –

to consult with you to avoid unnecessary destruction of cultural and biological resources, but also to protect what resources still exist at the project site for the benefit and education of future generations.

: Field Methods

At least One Native American Monitor will be present during ground disturbing activities (including but not limited to pavement removal , pot- holing or auguring ,boring , grading , excavation and trenching) within the project area. The Native American Monitor will complete monitoring Longs on a daily basis . The logs will provide descriptions of the daily activities, including construction activities, locations , Soil and any cultural materials identified . The monitor will photo-document the ground disturbing activities.

The following person is designated as our Tribe's lead contact person for the purposes of receiving notices of proposed projects from your agency: please keep us updated regarding this project.

With Respect

Direct Lineal Gabrieleño Descendant

Andrew Salas, Chairman

Gabrieleño Band of Mission Indians – Kizh Nation

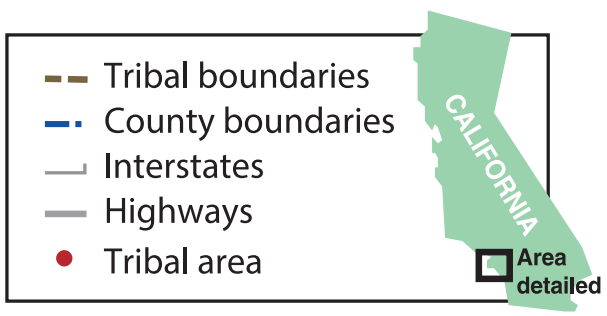
Fernandeño Tataviam Band of Mission Indians
Historical Tribal Territory



Tribal boundary depicted is based on registered tribal citizens' ancestral villages. Due to kinship networks and social exchange, this hard boundary does not include all of the abundant locations associated with Tataviam cultural resources and ancestry. Therefore, the overlap yellow boundary accommodates the natural mobility of ancestral and contemporary Tataviam people, which are also known to be well associated with the tribe and sensitive cultural resources.

All projects breaking soil within the tribal boundary are subject to Tataviam jurisdiction, whereas any projects occurring within the yellow boundary may be subject to further analysis by other surrounding Tribal Governments.

APPENDIX C

Preliminary Subsruface Methane Gas Investigation at Venice Auxiliary Pump Station, 133 East Hurricane Street, Los Angeles, CA prepared by GeoKinetics dated August 20, 2015.

1.0 INTRODUCTION

This Geotechnical Report presents the results of a geotechnical investigation conducted for the Venice Auxiliary Pumping Plant to be located at 133 East Hurricane Street in the Venice area of Los Angeles. This report was prepared in response to a request received from the Wastewater Conveyance Engineering Division dated September 10, 2014. This investigation was performed to evaluate subsurface characteristics and to provide geotechnical recommendations for design and construction of the proposed project.

This report is based on visual observation, subsurface investigation and laboratory testing. At the request of the Geotechnical Engineering Group (GEO), Geotechnical Professionals Inc. (GPI) performed subsurface exploration at the site and laboratory testing of samples collected from the site. The results of their field work and laboratory tests are included in their Data Report, dated September 29, 2015, presented in Appendix A of this report.

In addition, Amec previously prepared a Geotechnical Data Report as part of a geotechnical investigation for the Venice Dual Force Main project. Their scope of work included two exploratory borings (G-1A and G-1B) in the southeast portion of the Venice Auxiliary Pumping Plant site. Logs of these exploratory borings and laboratory test results of samples retrieved from these borings are presented in Appendix B of this report.

Also, the Department of General Services Standards Division previously advanced two exploratory borings on the site in support of previous projects. Logs of these exploratory borings and laboratory test results of samples retrieved from these borings are presented in Appendix B of this report.

GEO has reviewed the above referenced reports and concurs with the findings and accepts responsibility for the use of the contents as described herein.

2.0 SITE DESCRIPTION

The Venice Auxiliary Pumping Plant site consists of an approximately 7,800 square foot piece of land bounded by private property to the northwest, the Grand Canal to the northeast, Hurricane Street to the southeast and Canal Street to the southwest. The site is across Hurricane Street from the existing Venice Pump Plant. At the time this report was prepared, the site was unoccupied. The site was recently used to facilitate construction of the Venice Manifold Replacement project. Site ground surface elevations are on the order of 5 to 6 feet above sea level. Figure 1, "Vicinity Map", illustrates the site location.

3.0 PROJECT SCOPE

In preparation of this report we have reviewed an October 2105 draft of the Preliminary Design Report for the project, prepared by Arcadis. Appendix B of the draft Preliminary Design Report includes several preliminary design drawings. Drawing C-03A illustrates a proposed layout of the planned construction. As shown on this drawing, the project is planned to consist of an auxiliary pumping plant (wetwell/valve vault), an electrical building, a diversion structure, a new 66-inch diameter sewer between the diversion structure and the new auxiliary pumping plant wetwell, and a new 42-inch discharge line to connect to the existing force main. Drawing C-03A has been reproduced herein as Figure 2, "Proposed Construction".

Preliminary Design Drawing C-03A indicates the auxiliary pumping plant (wetwell/valve vault) will be located in the east central portion of the site and that this structure is anticipated to have plan dimensions on the order of 55 feet by 32 feet. Preliminary Design Drawing S-2 indicates the wetwell will be founded on a mat foundation with a bearing elevation on the order of -26 feet (below sea level) and the valve vault at an elevation on the order of -9 feet (below sea level).

Preliminary Design Drawing C-03A indicates the new electrical building will be located in the west central portion of the site and will have plan dimensions on the order of 25 feet by 50 feet. Preliminary Design Drawing A-04 indicates this building will be an at-grade, two-story structure with an overall height on the order of 30 feet. The finish floor elevation of the ground level floor is expected to be on the order of 6 feet above sea level.

Preliminary Design Drawing C-03A indicates the diversion structure will encompass an existing 66-inch reinforced concrete sewer pipe that extends along the east side of the site. This structure is anticipated to have plan dimensions on the order of 21 feet by 21 feet and is expected to be founded on a mat foundation bearing at an elevation of approximately -20 feet (below sea level).

Approximately 23 feet of new 66-inch diameter reinforced concrete sewer pipe will be constructed between the new diversion structure and the auxiliary pumping plant wetwell. Preliminary Design Drawing S-3 indicates this sewer will have an invert elevation of -7.37 feet (below sea level).

A new 42-inch diameter pipe header is shown on Preliminary Design Drawing C-03A to extend from the new valve vault to the west end of the new manifold within Hurricane Street. Preliminary Design Drawing M-02 indicates this pipe header will have an invert elevation on the order of -4.75 feet (below sea level).

Construction will also include new equipment pads and possibly sidewalks, planters, landscaping, and other minor improvements. Final site grades are expected to be within one to two feet of the current site grades.

The analyses and recommendations of this report reflect the layout of major improvements provided in Figure 2, but are also intended to be flexible to allow minor changes in the scope. GEO shall review the final project scope and grading plans to confirm that the recommendations contain within this report are appropriate. If the final scope includes significant changes from those described herein, a supplemental report will be necessary.

4.0 EXPLORATION PROGRAM

4.1 Subsurface investigation 2015

Five Cone Penetrometer tests (CPT's) were performed for the project on July 31, 2015. The CPT's were advanced to approximate depths of 40 to 80 feet below ground surface (bgs). In addition, three rotary wash boring were drilled on August 6 and 7, 2015 to depths of 49 feet to 79-1/2 feet bgs. Approximate locations of the CPTs and exploratory borings are shown in Figure 3, "Exploration Locations Map" and in the data report presented in Appendix A.

Relatively undisturbed geotechnical samples were obtained from the rotary wash borings by driving a modified California-type split spoon sampler lined with 1-inch high brass rings. Standard Penetration Tests (SPT) were also performed in these borings. Starting began at a depth of 2.5 feet and was performed every 2.5 feet thereafter to the final depth of the borings. The samplers were driven with successive drops of a 140-pound automatic-trip hammer falling 30 inches.

Each collected sample was inspected and described in general conformance with the Unified Soil Classification System (USCS). All samples were sealed and packaged for transportation to GPI's laboratory. After completion of drilling and sampling, the borings were backfilled with cement slurry.

Although GEO has no record of contamination at the project site, the samples obtained from the borings were screened in the field for volatile organic compounds (VOCs) to determine if the site may have been contaminated in the past by petroleum distillates or other types of contamination. Soil samples were screened in the field with a photo-ionization detector. No organic vapors were detected. No odor, staining, or other evidence of contamination was observed in the borings.

The site is located within a Methane Study Zone and a Methane Study has been performed for the project. The requirements of the Methane Study report shall be incorporated into the design and construction of the project. A copy of the methane report is presented in Appendix C of this report.

4.2 Subsurface investigation 2008

In 2008, Amec drilled two exploratory borings (G-1A and G-1B) within the southeastern portion of the site as part of a subsurface investigation for the Venice Dual Force Main project. Ring, Standard Penetration Test (SPT) and shelby tube samples were collected from exploratory boring G-1A at depth intervals of 2-1/2 to 5 feet to the explored depth of approximately 71.5 feet below the ground surface. Ring and SPT samples were collected from exploratory boring G-1B at depth intervals of 2-1/2 to 5 feet to the explored depth of approximately 25.5 feet below the ground surface. Ring and SPT samplers were driven into the bottom of the borings with successive drops of a 140-pound Automatic trip hammer falling 30 inches. Approximate locations of these borings are shown on Figure 3.

Each collected sample was inspected and described in general conformance with the Unified Soil Classification System (USCS). All samples were sealed and packaged for transportation to Amec's laboratory. After completion of drilling and sampling, the borings were converted to monitoring wells.

Soil samples obtained from the borings during exploration were field-screened for the presence of organic vapors using a MiniRAE 2000, a portable photo-ionization detector (PID). Results of the PID screening are presented in the boring logs (Appendix B).

A portable combustible gas meter (CGM), RAE QRAE Plus 4, capable of measuring the Lower Explosive Limit (LEL) of potential gases, the percent of oxygen, carbon monoxide (CO), and hydrogen sulfide gases (H_2S), was used to measure the LEL at the ground surface. For these borings, only zero readings were recorded, and thus the values are not shown on the boring logs.

4.3 Subsurface investigation 1994

In 1994, the Department of General Services Standards Division drilled one exploratory boring (94-072 B-8) within the eastern portion of the site as part of a subsurface investigation for the Venice Area Relief sewer project. Standard Penetration Test (SPT) samples were collected from this exploratory boring at depths of 5 feet, 10 feet and every 5 feet thereafter to the explored depth of approximately 31 feet below the ground surface. The SPT samplers were driven into the bottom of the borings with successive drops of a 140-pound hammer falling 30 inches. The approximate location of this boring is shown on Figure 3.

Each collected sample was inspected and described in general conformance with the Unified Soil Classification System (USCS). All samples were sealed and packaged for transportation to the Standards laboratory. After completion of drilling, the exploratory boring was backfilled with soil cuttings. An exploratory boring log and laboratory test results of samples retrieved from this boring are presented in Appendix B.

4.4 Subsurface investigation 1990

In 1990, the Department of General Services Standards Division drilled one exploratory boring (89-305 B-2) within the western portion of the site as part of a subsurface investigation for a seismic evaluation of the existing Venice Pumping Plant. Standard Penetration Test (SPT) samples were collected from this exploratory boring at depths of 5 feet, 10 feet and every 5 feet thereafter to the explored depth of approximately 41 feet below the ground surface. The SPT samplers were driven into the bottom of the borings with successive drops of a 140-pound hammer falling 30 inches. The approximate location of this boring is shown on Figure 3.

Each collected sample was inspected and described in general conformance with the Unified Soil Classification System (USCS). All samples were sealed and packaged for transportation to the Standards laboratory. After completion of drilling, the exploratory boring was backfilled with soil cuttings. An exploratory boring log for this boring is presented in Appendix B.

5.0 GEOLOGIC CONDITIONS

5.1 Regional Geology

The Venice Auxiliary Pumping Plant site is located within the Los Angeles Basin part of the Peninsular Ranges geomorphic province, which extends from Southern California to the southern tip of Baja California. This province is characterized by elongate northwest-trending mountain ridges separated by straight-sided sediment-filled valleys. The northwest trend is further displayed in the dominant structural features of the province, which are northwest to west-northwest trending folds and faults, such as the nearby Newport-Inglewood fault zone.

The site is located in an alluviated lowland area in the west portion of the Los Angeles Basin, a northwest trending alluviated plain about 50 miles long and 20 miles wide. The Basin is bound on the north by the Santa Monica Mountains and the Elysian, Repetto, and Puente Hills, and on the east and southeast by the Santa Ana Mountains and San Joaquin Hills. The aerially extensive alluviated plain slopes southward and seaward however in the vicinity of the project the plain is interrupted by the Baldwin Hills and Beverly Hills. The Baldwin Hills are the northern extension of the Newport-Inglewood structural block which has uplifted the Baldwin Hills, Dominquez Hills, and Signal Hill located to the south.

The Los Angeles Basin is underlain by a deep structural depression. Parts of this depression have been filled with sediments discontinuously since the Late Cretaceous (starting about 85 million years ago). Starting in the middle Miocene (about 20 million years ago) the basin (which extended to the Ventura Basin) continuously subsided as sediments were deposited. The buried basement surface has relief of as much as 4.5 miles in a distance of 8 miles (Yerkes, et al, 1965).

5.2 Local Geologic Setting

The Marina Del Rey and Venice areas were once a large wetland marsh fed by the meandering Ballona Creek, which drained into the Santa Monica Bay near the current location. The 1924 United States Geological Survey Map of the Venice Quadrangle shows the project site is adjacent to a large lowland marsh area northeast of the Grand Canal. The elevation of the site was approximately 5 feet above sea level. Surficial geologic exposures are all Quaternary Age sedimentary units.

5.3 Stratigraphy

5.3.1 Fill (af)

Artificial fill soils exist within the site as the result of previous construction and/or previous construction activities on the site. In general, the depth of fill is expected to be on the order of three to four feet within the site. Fill depths may be deeper in some areas. The fill materials generally consist of silty sand and sand with some construction debris.

5.3.2 Alluvium (Qa)

Alluvial sediments encountered in the borings were primarily coarse grained soils consisting of gravels, sands, and silty sands with interlayered fine grained soils consisting of silts and clays.

Coarse-grained alluvial materials range widely in type and consistency from poorly graded sands and gravels to silty and clayey sands. Generally, the coarse alluvium soils are typically brown or light brown in color though they may be gray or olive with high fine contents in the case of silty or clayey sands. The coarse grained materials are moist to wet, loose to very dense with varying amounts of silt, clay, gravel, and cobbles.

The fine-grained materials are typically moist to wet. Fine-grained alluvium consists of lean and fat (low to high plasticity) silts and clays of very soft to hard consistency. Generally, the fine grained alluvial soils are brown, dark brown, dark gray or greenish gray in color.

Seashells and seashell fragments were observed in many of the samples collected from the borings. These materials were observed to be interspersed anywhere within the matrix of the soil and as concentrated lenses and layers of several inches in thickness.

More detailed descriptions of the alluvium can be found in the boring logs in Appendices A and B.

5.4 Groundwater

The Grand Canal and the Venice Canals convey surface water runoff from nearby areas to the Marina Del Rey entrance channel. The Marina Del Rey harbor and entrance channel are also unlined, and was constructed via dredging in the 1950's. In order to reduce the chance of flooding low lying areas along the Grand Canal, the County of Los Angeles maintains tide gates that control flow into and out of the Grand Canal from the Marina Del Rey entrance channel. County personnel report that when a high tide in excess of 5.7 feet above sea level is forecast, the tide gates are closed. In the past, when tide gates were not closed, water levels in the Grand Canal increased and local flooding resulted. Historically, groundwater levels have been measured near the ground surface in the project area.

Measured groundwater levels in the project area have generally varied between elevations of -2 to +4 feet of sea level. Groundwater levels beneath the site fluctuate as the result of seasonal variations and tidal fluctuations. Based on the available geotechnical data, a baseline groundwater elevation of one foot above sea level has been selected for the project.

6.0 FAULTING AND SEISMICITY

The site lies within Seismic Zone 4 of the 2010 California Building Code (CBC). Primary seismic hazards that could affect the site include ground motion or shaking, ground surface rupture along faults, liquefaction, and earthquake-induced landslides.

6.1 Ground Motion

Based on the current understanding of the geologic framework of the site area, the seismic hazard which is expected to have the highest probability of affecting the site is ground shaking or motion resulting from an earthquake occurring along any of several major active and potentially active faults in Southern California. Known regional faults that could produce significant ground shaking at the site include the Malibu Coast, Santa Monica, Palos Verdes, Newport-Inglewood, among others.

Ground motion parameters were determined for the site using the United States Geological Survey (USGS) 2008 Probabilistic Seismic Hazard Analysis Interactive Deaggregation web tool. The site longitude and latitude, a 10% probability of

exceedance in 50 years and an average shear wave velocity of 230 meters per second for the upper 100 feet of subsurface were input into the program. Using these parameters a peak ground acceleration of 0.4g was determined for the site. The program also calculated a mean earthquake magnitude of 6.7 at a distance of 20.5 kilometers from the site.

6.2 Ground Rupture and Deformation

The Alquist-Priolo Earthquake Fault Zoning Act of 1972 (Act) requires that "Earthquake Fault Zones" be established along the trace of active faults. The purpose of the Act is to regulate development near active faults so as to mitigate the hazard of surface fault rupture. Earthquake faults that are "sufficiently active" (have evidence of surface displacement within Holocene time or the last 11,000 years) and "well-defined" (a fault whose trace is clearly detectable by a trained geologist as a physical feature at or just below the ground surface) are subject to zoning. Under the Act, the State Geologist is required to delineate Earthquake Fault Zones along all sufficiently active and well-defined faults that constitute a hazard to structures from surface displacement. Maps depicting the Earthquake Fault Zones are issued by the California Geological Survey (CGS). According to the CGS, the site is not located within an Alquist-Priolo Earthquake Fault Zone and no faults are known to be in close proximity of the site.

6.3 Liquefaction

According to the State of California Seismic Hazard Zones Map (Figure 4), the site is located within an area that has potential for liquefaction. Liquefaction is a process that occurs when saturated sediments are subjected to repeated strain reversals during a seismic event. The strain reversals cause an increase in pore water pressure such that the internal pore pressure approaches the overburden pressure and the shear strength approaches a low residual value. Liquefied soils are subject to flow, consolidation, or excessive strain. Liquefaction typically occurs in loose to medium dense sand and silty sand soils below the groundwater table. Predominately fine-grained soils, such as silts and clays are less susceptible to liquefaction.

Liquefaction analyses were performed for a ground acceleration of 0.43g (2/3 of the Maximum Considered Earthquake-Geometric Mean ground acceleration of 0.642g). The analyses were performed for the deepest rotary wash boring, RW-2, located near the center of the site. The analyses were performed with consideration to the soil particle size and plasticity information obtained through laboratory testing, and the measured and anticipated high groundwater levels. Potential liquefaction induced settlements on the order of 1-3/4 inches were calculated for the project site.

6.4 Earthquake-Induced Landslides

As shown by the State of California Seismic Hazard Zones Map (Figure 4), the site is not within a zone of earthquake-induced landslide potential.

6.5 Seismic Design Parameters

Table 1613.5.2 of 2013 California Building Code - "Site Class Definitions" list six Site Classes (A through F). The Site Class is based on the average properties of the upper 100 feet of the soil and/or bedrock beneath the site. The appropriate Site Class is chosen by referencing the average shear wave velocity, average Standard Penetration Test blow counts, and/or average undrained shear strength. Based on data obtained from the deepest boring, Site Class D is recommended for this site.

The mapped acceleration parameters Ss and S_1, 0.2 and 1-second spectral response accelerations, were determined and used along with the Site Class to obtain the site coefficients Fa and Fv. The maximum considered earthquake spectral response acceleration for short periods, S_{MS}, and at the 1.0-second period, S_{M1}, adjusted for Site Class effects were then calculated followed by the calculation of the design spectral response acceleration for short periods, S_{DS}, and at the 1.0-second period, S_{D1}. The values of T_O and T_S, in seconds, were then determined using the equations presented in the code to represent the beginning and end of the design response spectra peak.

The seismic parameter values for the site are summarized in Table 1, Seismic Design Parameters.

Table 1 – Seismic Design Parameters

Parameter	Value	2008 LABC Reference
Site Class	D	Table 1613.5.2
S_s	1.661	Figure 1613.5(3)
S_1	0.660	Figure 1613.5(4)
S_{MS}	1.661	Equation 16-37
S_{M1}	0.990	Equation 16-38
S_{DS}	1.107	Equation 16-39
S_{D1}	0.660	Equation 16-40
T_O (seconds)	0.119	Chapter 16
T_S (seconds)	0.596	Chapter 16

7.0 LABORATORY TESTING

Selected soil samples were tested for the following properties:

- In-Place Dry Density and Field Moisture (D2937)
- Laboratory Maximum Dry Density and Optimum Moisture Content (ASTM D1557)
- Consolidation (ASTM D 2435)
- Direct Shear (ASTM D 3080)
- Unconfined Compression Strength (ASTM D 2166)
- Triaxial Compresion Strength (ASTM D2850)
- Sieve and Hydrometer Analysis (ASTM D422)
- Liquid Limit and Plasticity Index (ASTM D4318)
- Conductivity (EPA 120.1)
- Chlorides (EPA 300.0)
- pH (SM 4500-H+B)
- Sulfates (EPA 300.0)

Laboratory test results are presented in Appendices A and B.

8.0 SITE RECOMMENDATIONS

8.1 General

Our primary geotechnical consideration with respect to the proposed construction is the existing uncertified fill soils and compressible shallow soils within the site, the potential for liquefaction at the site, and the potential for methane gas. Remedial earthwork is recommended in the area of the electrical building to provide suitable foundation support. To mitigate the potential effects of soil liquefaction, we recommend the project structures be supported on concrete mat foundations. Mat foundations should be designed and constructed to accommodate the estimated potential total and differential seismic induced settlements presented herein. The requirements of the Methane Study report shall be incorporated into the design and construction of the project. A copy of the methane report is presented in Appendix C of this report.

Detailed geotechnical engineering recommendations addressing the surficial soils, site preparation, site earthwork, foundations and retaining walls are presented in the remaining portions of this report. The following opinions, conclusions, and recommendations are based on the properties of materials encountered in the geotechnical field investigations and laboratory test results.

A representative of GEO will need to provide observation and testing services during site earthwork and construction of foundations. This will allow us the opportunity to compare actual conditions with those encountered in the exploratory borings and, if necessary, to expedite supplemental recommendations if warranted by the exposed subsurface conditions. We shall also review the preliminary foundation and earthwork plans and specifications. Specifications for groundwater control and discharge, shoring and jet grouting shall also be reviewed by our office. These reviews will provide us an opportunity to detect misinterpretation or misunderstandings of our recommendations prior to advertising the project for construction.

8.2 Site Clearing

Prior to construction, all organic or inorganic materials shall be removed from the construction area and disposed of outside the site. Any existing structural or landscape elements within these areas, including any foundation elements, shall be demolished and removed from the site. Any utilities, whether active or inactive, shall be identified and removed from the site or relocated per project plans and specifications. Any cavities resulting from removal of any existing foundations or utility lines shall be properly backfilled and compacted in accordance with the following sections.

8.3 Groundwater Control During Construction

Dewatering from outside of excavations is not allowed. Continuous, solid impervious shoring extending below planned excavation depths, to act as a groundwater cut-off, is required for all excavations that extend more than 3 feet below the baseline groundwater level. Acceptable methods of impervious shoring include sheet piles, secant piles or diaphragm walls.

In addition, Jet grouting shall be performed to create a structural and watertight bottom seal beneath the wetwell/vault structure and diversion structure. Jet grouting can also be used to create a bottom seal for the sewer pipe that will be constructed between the new diversion structure and the auxiliary pumping plant wetwell and the 42-inch header pipe. The zones of jet grouting shall extend from the bottom of proposed excavation to an elevation of at least -35 feet (below sea level). Jetted grouted bottom seals shall be in-place prior to excavating below the baseline groundwater level.

Actual plan dimensions and depths of the jetted grouted bottom seals shall be designed by a specialty geotechnical contractor and endorsed by a Geotechnical Engineer or Engineering Geologist with at least five years of experience in groundwater control applications in excavations. Calculations supporting the design dimensions of the treatment areas shall be provided to demonstrate that the goals of the treatment will be fulfilled and that the treated areas will have adequate factors of safety against bottom heave and piping.

Carefully controlled dewatering, in combination with continuous impervious shoring functioning as a groundwater cut-off, may be used to control groundwater to facilitate construction of the 66-inch diameter reinforced concrete sewer pipe as an alternative to jet grouting. This method of dewatering can also be used to facilitate construction of the 42-inch header pipe. For this method, impervious shoring shall be installed to extend from the ground surface to an elevation of -25 feet (below sea level) or deeper. Dewatering wells shall be located within the shored excavations and shall be constructed with the well points above the bottom of the shoring. The dewatering system shall be designed, constructed and operated to lower the ground water level within the excavation to at least 3 feet below the bottom of the excavation without drawing down groundwater levels outside the excavations. Dewatering to below the planned depth of excavation shall be completed prior to excavating below the baseline ground water level. The drawn down groundwater level should be maintained at least three (3) feet below the bottom of excavations until construction has progressed above the surrounding static groundwater level and sufficient structural dead-load and backfill have been placed to counteract hydrostatic uplift pressures. Backfill may be assumed to have a unit weight of 105 (pcf) above groundwater. Submerged backfill may be assumed to have a buoyant unit weight of 42 pcf. Monitoring wells shall be installed outside of the excavations. The locations shall be approved by GEO. Groundwater recharge shall be performed as necessary to maintain groundwater levels outside of excavations at their natural levels.

Sump pumps shall be provided at the base of excavations which extend below the baseline groundwater level to facilitate removal of any water that seeps into the excavations through the shoring system.

Any groundwater pumped from excavations shall be discharged into nearby sanitary sewers and discharge rates into the sewers shall not exceed those allowed by the Bureau of Sanitation.

8.4 Temporary Sloped Excavations

Based on our observations during subsurface investigation and results of laboratory tests, the materials at the site should be readily excavated by conventional earthmoving equipment in good operating condition. All temporary excavations shall conform to the State of California Construction Safety Orders (CAL/OSHA).

In level areas, unsurcharged, temporary vertical excavations can be a maximum depth of four feet. Unsurcharged excavations greater than 4 feet, to a maximum of 8 feet, in level areas shall be sloped at a 1:1 (H:V) or flatter inclination from the ground surface to the bottom of the excavation or should be shored. Excavations greater than 8 feet should be shored.

Any excavation that enters the influence zone (imaginary plane extending downward at a 1:1 inclination) of an adjacent structure, private property or right-of-way subject to vehicle loading shall utilize shoring.

8.5 Excavation Support

8.5.1 Excavation Methods

Based on the available geotechnical data and construction experience in similar materials, it is anticipated that excavations can be achieved using heavy excavation equipment. The artificial fill and alluvium can be excavated with backhoes, clam shells, excavators, dozers, and other hydraulic equipment.

In sizing and laying out excavations, the Contractor must consider allowable construction limits shown on the Contract Drawings, requirements for construction of permanent structures (indicated on the Contract Drawings), as well as requirements for construction methods selected for the work. The following sections address excavation methods and support requirements.

8.5.2 Excavation Support Requirements

Excavations will require continuous support unless the soils are strengthened or stabilized by implementing an effective ground improvement technique. Acceptable excavation support systems for excavations that extend more than three feet below the baseline groundwater level include water-tight interlocking sheet piling, secant piles or diaphragm walls or other approved water tight shoring.

Dewatering or bottom seals placed "in the wet" are not permitted. The relatively water-tight excavation support systems shall extend a sufficient depth below the bottom of the planned excavations to prevent heave and/or piping of excavation bottoms. Design of the embedment depth of the water tight shoring below the base of excavations shall be based on the assumption that the extension is embedded in pervious granular soils with seashell lenses and layers. Ground treatment consisting of jet grouting below the excavation bottom is also required for the wetwell/valve vault structure and the diversion structure to further reduce groundwater in-flow and the potential for bottom instability. As an alternative to jet grouting, impervious shoring and dewatering in accordance with the recommendations of section 8.3 can be used to facilitate construction of the 66-inch diameter reinforced concrete sewer pipe and 42-inch header pipe. Calculations supporting the design of the shoring cut-off depth and depth of jet grouting below the excavation bottoms shall be included in the shoring submittal.

Shoring for excavations shall be installed in accordance with the General Requirements, the project specifications and Section 306-1.1.6 of the Standard Specifications for Public Works Construction (SSPWC), most current edition adopted by the Board of Public Works. Design of shoring shall be in accordance with Title 8, Division 1, Chapter

4, Subchapter 4 of the California Code of Regulations: CAL/OSHA Construction Safety Orders or the lateral earth pressure distributions recommended in the following section of this report. Based on the soil classification system presented in the Construction Safety Orders, the site soils shall be considered as Type C soils. All shoring systems shall be designed for maximum deflections of ½-inch.

Where bracing is used, each excavation sequence must be designed to allow removals of struts during construction of permanent facilities within excavations and as excavations are backfilled.

Sheet piles, if used shall be installed and extracted using vibration- and percussive-free methods. Coating should be applied to the sheet piles to prevent the soils from adhering to the sheet piles to facilitate removal of the sheet piles at the end of construction.

For secant pile shoring, casing or other methods approved by the geotechnical engineer of record shall be used to support the sides of pile excavations in the artificial fill and alluvial materials. The inside diameter of casing shall be at least as large as the diameter of the pile as indicated on the plans. Drilling shall be accomplished within the casing. Drilling fluids shall not be used to support the sides of the excavation without the review and approval of GEO.

All proposed shoring system designs including supporting documentation and calculations shall be submitted to GEO for review and approval in reference to existing soil conditions. All shoring systems must meet the following minimum requirements to be considered for review.

- Shoring shall directly support the sides of the excavation. Shoring shall be designed to minimize the development and presence of voids behind shoring support.
- Shoring installation procedures shall be designed so that no person is required to enter an unsupported excavation greater than 5 feet in depth at any time.

Trench box and shield systems are not allowed as shoring for the project. Trench box or shield systems do not adequately support the adjacent soil and utilities. Also, voids can occur between the outside of the box and the firm soil.

8.5.3 Design Earth Pressures

Temporary internally braced shoring shall be designed using a lateral soil equivalent fluid pressure of 48 pounds per cubic foot (pcf) above groundwater. Below groundwater, the design soil lateral earth pressure can be assumed to increase at a rate of 24 pcf for braced shoring. Cantilevered shoring shall be designed using an effective fluid pressure (EFP) of 36 pounds per cubic foot (pcf). Cantilevered shoring shall not be allowed in areas where existing utilities and structures are located within a 1:1 projection upward from the bottom of the planned excavation. Hydrostatic pressures shall be added to the

lateral earth pressures for the portions of shoring that extend below the baseline groundwater level. These design pressures assume level backslopes.

A surcharge load equivalent to an additional 2 feet of retained soil shall be applied to the upper 10 feet of shoring. The minimum surcharge load shall be 100 psf. Heavy construction equipment wheel or outrigger loads shall not be located within a distance equal to 0.7H feet the face of the shoring unless considered as surcharge loads in the Contractor's shoring calculations.

Allowable passive earth pressures equal to 150 pounds per square foot (psf) per foot of depth below groundwater and 300 psf per foot of depth above groundwater, measured below the base on the planned excavation, to a maximum value of 3,000 psf can be used for resistance in the alluvium materials.

8.6 Over-excavation

All existing fill materials shall be removed from the area of the proposed electrical building. This area shall be further excavated as necessary to a depth of seven feet below the existing ground surface or to three feet below the bottom of the proposed mat foundation, whichever is deeper. Over-excavation depths may have to be greater in some areas to remove unsuitable soils. Removal excavations should extend a horizontal distance beyond the edges of the foundations equal to the depth of over excavation below the foundations or a minimum of 5 feet, whichever is greater. All exposed subgrade soil surfaces shall be observed by a representative of the GEO and the City of Los Angeles Grading Inspector prior to placement of fill.

Shallow sump pumps may be necessary to control groundwater within the over-excavation area. The exposed soils in the over-excavation bottom may be susceptible to pumping. The contractor should take precautionary measures to avoid disturbance of the over-excavation bottom. Heavy construction equipment, such as trucks or rubber tired equipment should not be allowed to operate within the over-excavation area. Over-excavation should be accomplished with excavation equipment operating from outside the over-excavation area to the extent possible. With-in the over-excavation area, only low ground pressure equipment should be used to excavate, place and compact materials over the over-excavation bottom. Track-mounted equipment will lessen the softening of wet soils as a result of the "pumping" action of moving heavy wheel loads.

After over-excavating for the foundation of the electrical building, the following shall be performed;

- The exposed over-excavation bottom shall be observed by a representative of the GEO and the City of Los Angeles Grading Inspector. The bottom shall be smooth and uniform (free of ruts). If necessary, additional over-excavation shall be performed as directed by the GEO. If additional over-excavation isn't

necessary, the subgrade shall be prepared as directed by the GEO.

- Place a Geotextile fabric over the over-excavation bottom. The geotextile shall be placed in accordance with manufacturer's recommendations. The geotextile fabric shall be temporary extended up the excavation slopes. The geofabric shall comply with following minimum requirements: Density of 6 ounces per square yard or more, Grab Tensile Strength (ASTM D-4632) of 120 pounds, Grab Tensile Elongation (ASTM D-4632) of 50%, Trapezoidal Tear Strength (ASTM D-4533) of 50 pounds. No equipment should operate directly over the geotextile fabric.

- Place a 24-inch layer of 1-inch crushed rock over the entire over-excavated area. Densify the crushed rock using vibration and track walking. Cover the crushed rock with the geotextile fabric that was temporary extended up the slopes of the excavation. Use additional geotextile fabric to completely cover the crushed rock. Overlap all seams per the geotextile manufacturer's recommendations.

- Place an 8-inch layer of Crushed Miscellaneous Base (CMB) over the geofabric. The CMB shall be moisture conditioned and compacted to at least 95-percent relative compaction.

- If pumping is observed, additional base shall be placed in 6-inch lifts until pumping ceases.

- Once pumping ceases, place a geotextile fabric over the compacted base and place suitable fill materials in lifts of 8 inches or less in thickness (before compaction) to finish subgrade elevation (base on the methane mitigation system). Each lift shall be moisture conditioned and compacted as specified section 8.9 of this report.

Exterior slab-on-grade and any pavement areas, should be over-excavated to a depth of at least 12 inches below existing grade or the finish subgrade elevation, whichever is lower, and replaced with properly compacted fill. Removal excavations should extend a horizontal distance of at least 2 feet beyond the plan dimensions of slabs-on-grade or pavements.

8.7 Subgrade Preparation

All exposed subgrade soil surfaces shall be observed by a representative of the GEO and the City of Los Angeles Grading Inspector prior to placement of fill. If soft, yielding, or unsuitable soils are exposed at the subgrade surface, then the unsuitable soils should be removed and replaced with properly compacted fill soils. Due to the nature of the site soils and shallow groundwater levels, unsuitable soft wet soils will be encountered below the ground surface in some areas. If a suitable bottom is not

obtainable within a reasonable depth of the excavation subgrade elevation, supplemental recommendations will be provided during construction to stabilize areas of soft soils.

Subgrade surfaces suitable for fill placement should be scarified to a depth of 6 inches, moisture-conditioned and compacted. Subgrade soils shall be moisture conditioned to between optimum moisture content and 2 percent above the optimum moisture content, at the time of compaction, and compacted to a minimum of 95 percent of the ASTM Test Method D1557-91 laboratory maximum density to a depth of 6 inches. After the completion and acceptance of the subgrade preparation, fill material may be placed in accordance with Section 8.9 of this report. Subgrade soils shall be kept moist (between 0 and 2 percent above the optimum moisture content) but not flooded until covered with subsequent fill or construction.

8.8 Fill Materials

Fill soils shall consist of select on-site soils or approved import material. The on-site soils encountered during the geotechnical investigation are generally acceptable for use as fill material for this project. On-site clayey and silty soils (such as elastic silt encountered in boring RW-1 between 4 and 6 feet) may not be used as fill within the electrical building footprint, below slabs or behind retaining walls. Before being used as fill, on-site soils shall be cleaned of all organic or inorganic debris and all materials with any dimension larger than 3 inches. Drying of wet site soils or mixing of these soils with dryer soils may be required prior to being used as compacted fill. Import material for use as fill for this project shall be predominantly granular (minimum 80% passing number 4 sieve and 25% or less passing the number 200 sieve), non-expansive (EI less than 20), and shall be free of organic or inorganic debris, contamination and materials with any dimension larger than 3 inches. Import material shall be tested and approved by GEO prior to importing to the job site. GEO shall be notified a minimum of five working days prior to scheduled importing of soil to the project site.

8.9 Fill and Backfill Placement

Structural fill shall only be placed on approved surfaces/subgrades prepared in accordance with Section 8.7 of this report. Fill material shall be placed in loose lifts not exceeding 8 inches in thickness, moisture-conditioned between 0 to 2 percent over the optimum moisture content and mechanically compacted. Fill soils placed below building foundations or slabs-on-grade shall be compacted to a minimum of 95 percent relative compaction, as determined by ASTM Test Method D1557.

Fill soils placed in non-structural areas such as paved areas, sidewalks, and landscaped areas shall be compacted to a minimum of 90 percent relative compaction, as determined by ASTM Test Method D1557. Any aggregate base should be moisture-conditioned between optimum and two percent above optimum-moisture and compacted to a minimum of 95 percent relative compaction.

Fill compaction shall be tested and recorded by a certified compaction testing agency working under the direct supervision of GEO. Densification by flooding or jetting is not allowed. Compacted fill soils shall be kept moist, (at or slightly above the specified moisture content at the time of compaction) but not flooded, until covered with subsequent construction. If fill soils are softened or eroded by excessive moisture or construction disturbance, they shall be replaced or recompacted at the discretion of the Geotechnical Engineer before additional fill or construction is placed. Certification and inspection approvals for compromised soils are void and invalid.

8.10 Trench Backfill

Trench excavations for utility pipes may be backfilled with on-site soils under the observation of a representative of GEO. After utility pipes have been laid, properly bedded, and covered per the project specifications, they shall be backfilled to the ground surface or design subgrade with controlled backfill. Controlled backfill shall be moisture conditioned, placed and compacted in accordance with the recommendations presented in Section 8.9 of this report.

8.11 Liquefaction Considerations

Based on the data presented in Section 3 of this report and the results of the liquefaction calculations, potential liquefaction induced settlements on the order of 1-3/4 inches are estimated for the site. A potential liquefaction induced differential settlement of 1 inch is estimated between the proposed structures and the pipe header. These potential liquefaction induced settlements shall be considered and accounted for in the design and construction of the project.

8.12 Mat Foundations

Mat foundations are recommended for support of the project structures with the understanding that the foundations will be susceptible to liquefaction induced settlements. Mat foundations for the wetwell/valve structure and diversion structures shall be founded on natural soils that have been jet grouted to create an excavation bottom seal. The mat foundation for the electrical building shall be founded on compacted fill soil. Mat foundations shall be designed and constructed to bear at a depth of at least 24 inches below the lowest adjacent grade. Mat foundations can be designed for an allowable bearing capacity of 1,500 pounds per square foot. A coefficient of vertical subgrade reaction, for a 1-foot-square loaded area, of 100 kips per cubic foot (kcf) may be used for design of the mats.

Total static settlement of the proposed foundations, designed and constructed in accordance with the recommendations presented herein, should not exceed 1-inch. Differential static settlement should not exceed one-half of the total settlement. The majority of these settlements are expected to occur within a year of construction. In

addition, the foundation will also be potentially susceptible to seismically induced settlements. Potential total and differential seismically induced settlements of 1-3/4 inches or less and 1 inch have been estimated for the project structures. The structural design of the proposed structures should consider the possibility that the estimated magnitudes of seismically induced settlement could occur during the life of the structures. The actual magnitude of total and differential static settlements of the mat foundations will be a function of the structural design and stiffness of the mats.

Resistance to lateral loads can be provided by friction acting at the base of the foundation and by passive earth pressure. A coefficient of friction of 0.35 may be assumed with dead-load forces. An allowable passive lateral earth pressure of 250 psf per foot of depth up to a maximum of 2,500 psf may be used for sides of the foundation poured against undisturbed natural soil or properly compacted fill. The allowable passive pressure may be increased by 33 percent of lateral loading due to wind or seismic forces.

8.13 Retaining Walls

Cantilevered retaining walls that retain a level granular (sand equivalent of 30 or greater) non-expansive backfill for a horizontal distance equal to or greater than the height of the wall may be designed for an active equivalent fluid pressure of 30 pcf. Walls that are fixed against rotation (no movement allowed) supporting a level ground surface and retaining native soils or granular (sand equivalent of 30 or greater) non-expansive backfill for a horizontal distance equal to or greater than the height of the wall can be designed using at-rest uniform pressure of 27H psf. Hydrostatic pressures shall be added to the lateral earth pressures for the portions of retaining walls that extend below the baseline groundwater level. A lateral seismic load of 24 psf per foot of height starting from 0 at the base of the retaining walls and increasing to a maximum at the top of the retaining walls can be considered for seismic conditions.

In addition to the above lateral pressures from retained earth, lateral pressures from other superimposed loads, such as those from vehicle traffic and adjacent structures, should be added, if the loads fall within a 1:1 projection of wall foundations. The effects of any surcharge loads should be added to the above recommended lateral earth pressures.

Backfill behind retaining walls should consist of free-draining granular soil as described in Section 8.8. Backfill should be placed in 8-inch or thinner loose lifts and compacted to a minimum of 90 percent of the ASTM Test Method D1557 maximum density. Compaction should be performed by mechanical means only and monitored by testing during construction. Care should be taken not to damage walls during backfill operations. Concrete should attain the strength specified by the structural designer prior to placement of large quantities of backfill.

Earth pressures presented herein also assume that only hand operated compaction equipment will be used within five feet of walls to limit compaction lateral stresses. The operation of compaction equipment behind retaining walls can induce horizontal pressures in excess of the at-rest pressures on the wall. To help reduce the development of excessive horizontal pressures over-compaction should be avoided.

Earth pressures used in the design of the walls should be indicated on the retaining wall plans. All retaining wall designs and plans should be reviewed by the project geotechnical consultant to confirm that the appropriate soil parameters are used.

Final surface grades should be sloped at a gradient such that surface water drains away from structures and retaining walls.

8.14 Cement Type and Corrosion Measures

Based on the results of soluble sulfate content testing of near-surface soils and our understanding of the proposed improvements, GEO recommends that Type II or Type V cement be used. Based on other test results including pH, chloride content, acidity, and conductivity, the site soils are moderately to severely corrosive. A corrosion expert should make the final determination of what corrosion measures are necessary for the project.

9.0 SUPPLEMENTAL GEOTECHNICAL SERVICES

9.1 Review of Plans and Specifications

The grading and foundation plans and specifications should implement the recommendations presented in this report and should be reviewed by GEO to ensure proper interpretation and application of our recommendations.

9.2 Geotechnical Observation and Testing During Construction

All grading, excavation, and construction of foundations should be performed under the observation and testing of the Geotechnical Engineer at the following stages:

- Upon completion of site clearing;
- During shoring installation;
- During jet grouting;
- During site excavation;
- During subgrade preparation;
- During fill placement;

- After excavation of foundations and immediately prior to placement of foundation concrete;
- During excavation and backfilling of all utility trenches; and
- When any unusual or unexpected geotechnical conditions are encountered

APPENDIX A

GPI GEOTECHNICAL PROFESSIONALS INC

September 29, 2015

City of Los Angeles
Department of Public Works Bureau of Engineering
Geotechnical Engineering Group
1149 South Broadway, Suite 120
Los Angeles, California 90015

Attention: Mr. Christopher F. Johnson
Manager, Geotechnical Engineering Group

Subject: Data Report
Geotechnical Investigation for
Venice Auxiliary Pump Plant (VAPP)
133 E. Hurricane Street
Venice Area of Los Angeles, California
Contract No. C-121601, Work Order No. SZC 12923
GPI Project No. 2500.06I

Dear Mr. Johnson:

This report presents geotechnical data from a subsurface field investigation and laboratory testing performed by Geotechnical Professionals Inc. (GPI) for the subject project. The site location is presented in Figure 1.

SCOPE OF WORK

The scope of the geotechnical investigation presented in this report was developed by the Geotechnical Engineering Group (GEO) of the City of Los Angeles Department of Public Works, as outlined in Task Order Solicitation No. 14-103 and further updated by GEO staff. We understand that GEO will review the data from this investigation and will be responsible for geotechnical recommendations for the subject project, as the Geotechnical Engineer of Record.

The full scope of work under the subject task order included a geotechnical investigation and a methane investigation. This report presents the results of the geotechnical investigation only. A separate methane investigation was performed by GeoKinetics under subcontract with GPI. Their report was submitted on August 20, 2015.

The geotechnical field investigation included five cone penetration tests to depths ranging from 40 to 80 feet and three rotary wash borings to depths ranging from 40 to 80 feet. The locations of the subsurface explorations were selected by GEO and marked in the field with GPI on July 28, 2015. The approximate locations are presented in Figure 2. A detailed description of CPT field procedures and results, including graphical CPT logs with site-specific soil descriptions, tabular data summaries and shearwave velocity measurements are presented in Appendix A. Field procedures and logs of the rotary wash borings are presented in Appendix B.

5736 Corporate Avenue • Cypress, CA 90630 • (714) 220-2211 • FAX (714) 220-2122

Geotechnical laboratory testing, as requested by GEO, included the following types and number of tests:

- 19 Moisture and Density (ASTM D 2216)
- 8 Percent Passing No. 200 Sieve (ASTM D 1140)
- 16 Full Sieve Analyses (ASTM D 6913)
- 5 Atterberg Limits (ASTM D 4318)
- 1 Compaction (ASTM D 1557)
- 3 Consolidation Tests (ASTM D 2435)
- 8 sets Direct Shear Tests (ASTM D 3080)
- 2 Unconfined Compression (ASTM D 2166)
- 2 Unconsolidated Undrained Triaxial Test (ASTM D 2850)
- 1 Expansion Index (ASTM D 4829)
- 2 sets Corrosivity (California Test Methods 417, 422, 643)

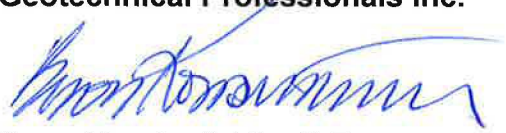
A detailed description of laboratory test procedures and results are presented in Appendix C.

CONCLUDING REMARKS

GPI warrants that the services covered by this report were performed as requested by GEO, in accordance with the standard procedures indicated, and with the standard of care of the geotechnical engineering profession in Southern California at this time. No other warranty or representation is included or intended in this report.

We appreciate the opportunity of offering our services on this project. Do not hesitate to call us if you have any questions on the contents of this report.

Respectfully submitted by,
Geotechnical Professionals Inc.



Byron Konstantinidis, G.E.
Principal

APPENDIX A

CONE PENETRATION TESTS

The subsurface conditions were investigated by performing five Cone Penetration Tests (CPT's) at the site. The soundings were advanced to depths ranging from 40.5 to 80.5 feet below existing grades. The locations of the CPT's are shown on the Site Plan, Figure 2. The latitude and longitude of each CPT location and distances from the northeastern and northwestern fences at the site are presented below:

CPT No.	Latitude	Longitude	Distance (feet)	
			from NE Fence	from NW Fence
C-1	33° 58' 34.44"	-118° 27' 40.62"	32	8
C-2	34.03"	40.33"	22	48
C-3	34.29"	40.89"	48	9
C-4	33.98"	40.67"	51	48
C-5	34.12"	41.13"	75	16

The Cone Penetration Test consists of pushing a cone-tipped probe into the soil deposit while simultaneously recording the cone tip resistance and side friction resistance of the soil to penetration (refer to Figure A-1). The CPT's described in this report were conducted in general accordance with ASTM specifications (ASTM D 5778) using an electric cone penetrometer.

The CPT equipment consists of a cone assembly mounted at the end of a series of hollow sounding rods. A set of hydraulic rams is used to push the cone and rods into the soil while a continuous record of cone and friction resistance versus depth is obtained in both analog and digital form at the ground surface. A specially designed truck is used to transport and house the test equipment and to provide a 30-ton reaction to the thrust of the hydraulic rams.

Standard data obtained during a CPT consists of continuous stratigraphic information with close vertical resolution. Stratigraphic interpretation is based on relationships between cone tip resistance and friction resistance. The calculated friction ratio (CPT friction sleeve resistance divided by cone tip resistance) is used as an indicator of soil type. Granular soils typically have low friction ratios and high cone resistance, while cohesive or organic soils have high friction ratios and low cone resistance. These stratigraphic material categories form the basis for all subsequent calculations which utilize the CPT data.

Computer plots of the reduced CPT data acquired for this investigation are presented in Figures A-2 to A-6 of this appendix. The field testing and computer processing was performed by Kehoe Testing and Engineering under subcontract to Geotechnical Professionals Inc. (GPI). The interpreted soil descriptions were prepared by GPI.

The CPT locations were laid out in the field by measuring from existing site features. Upon completion, the uncaved portions of the CPT holes were backfilled with bentonite chips.

Ground surface elevations at the CPT locations were estimated from Google Earth and should be considered very approximate.

The cone penetrometer used for the project was equipped with a pore pressure transducer to measure both transient and stabilized pore pressures. At selected depths in sandy soils, the penetration was stopped until stabilized pore pressures were obtained as an indication of the static piezometric groundwater levels. The piezometric measurements are summarized below.

CPT NO.	Depth (ft)	Static Pore Pressure (psi)	Piezometric Groundwater Depth (ft)
C-2	18.8	6.2±	4.5
C-2	37.7	13.9	5.6
C-3	21.5	7.0±	5.3
C-3	37.8	13.7	6.1

The cone penetrometer was also equipped with a tri-axial geophone set and impact source for obtaining shear wave velocity measurements versus depth in accordance with ASTM D 7400-08. Such measurements were obtained at 5-foot depth intervals in CPT C-4. The results of the measurements are summarized below:

Tip Depth (ft)	Geophone Depth (ft)	Travel Distance (ft)	S-Wave Arrival (msec)	S-Wave Velocity from Surface (ft/sec)	Interval S-Wave Velocity (ft/sec)
5.16	4.16	6.50	9.76	666.42	
10.05	9.05	10.34	16.54	625.11	565.65
15.07	14.07	14.93	25.47	586.26	514.29
20.10	19.10	19.74	34.62	570.29	525.86
25.22	24.22	24.73	41.43	596.93	732.32
30.13	29.13	29.56	54.58	541.52	366.94
35.14	34014	34.50	62.96	548.03	590.48
40.12	39.12	39.44	67.44	584.79	1101.35
45.06	44.06	44.34	71.58	619.49	1184.68
50.08	49.08	49.33	76.05	648.71	1116.61
55.01	54.01	54.24	81.35	666.76	925.83
60.04	59.04	59.25	86.39	685.86	994.13
64.98	63.98	64.18	90.14	711.95	1313.00
70.14	69.14	69.32	95.61	725.03	940.67
75.04	74.04	74.21	99.75	743.95	1180.70
80.11	79.11	79.27	103.41	766.54	1382.30

Notes:

1. Shear Wave Source Offset = 5 ft
2. S-Wave Velocity from Surface = Travel Distance/S-Wave Arrival
3. Interval S-Wave Velocity = (Travel Dist2-Travel Dist1) / (Time2-Time1)

APPENDIX B

APPENDIX B

EXPLORATORY BORINGS

The subsurface conditions at the site were investigated by drilling and sampling three rotary wash borings. The borings were advanced to depths ranging from 39.5 to 79.5 feet below the existing ground surface. The locations of the explorations are shown on the Site Plan, Figure 2. The latitude and longitude of each boring location and distances from the northeastern and northwestern fences at the site are as follows:

Boring No.	Latitude	Longitude	Distance (feet)	
			from NE Fence	from NW Fence
RW-1	33° 58' 34.48"	-118 27' 40.44"	7	11
RW-2	34.12"	40.71"	49	25
RW-3	33.73"	40.83"	75	68

Relatively undisturbed soil samples were obtained using two types of samplers. Thin walled Shelby tubes were used to obtain samples of relatively compressible silts and clays, in accordance with ASTM D 1587-08. The tubes were 30 inches long, had an inside diameter of 2.87 inches and an outside diameter of 3.00 inches. The Shelby tubes were pushed into the soils by hydraulic pressure. Thicker-walled, brass-ring lined samplers were used to sample mainly more granular soils and some cohesive soils, in accordance with ASTM D 3550-01. The sampler had an inside diameter of 2.42 inches and outside diameter of 3.25 inches. The sampler was driven into the soil using an automatic trip hammer weighing 140 pounds and dropping 30 inches. After seating the sampler into the soil 4 inches, the number of blows needed to drive the sampler 12 inches was recorded as the penetration resistance.

Relatively disturbed samples were also obtained using a split-spoon sampler by means of the Standard Penetration Test (SPT, ASTM D 1586-11). The spoon sampler was driven into the soil by a 140-pound hammer dropping 30 inches, employing the automatic trip hammer described above. The number of blows for each 6 inches of penetration was recorded and is presented on the logs. The blowcount for the first increment should be considered the seating blows while the sum of blows for the last 12 inches of penetration is considered the Standard Penetration Test blowcount. These values are the raw uncorrected blowcounts.

Bulk samples of the soils within the upper 4 feet were obtained with an auger at all boring locations.

The field explorations for the investigation were performed under the continuous technical supervision of GPI's representative, who visually inspected the site, maintained detailed logs of the borings, classified the soils encountered, and obtained relatively undisturbed samples for examination and laboratory testing. The soils encountered in the borings were classified in the field and through further examination in the laboratory in accordance with the Unified Soils Classification System. Detailed logs of the borings are presented in Figures B-1 to B-3 in this appendix. Laboratory test results of moisture content, density,

fines content (fraction passing No. 200 sieve) and Atterberg Limits are presented on the logs. For other laboratory tests, the type of test performed is shown with the following abbreviations:

CON – Consolidation Test
DS – Direct Shear Test
UC – Unconfined Compression Test
UU – Unconsolidated Undrained Triaxial Test

At selected depth intervals, soils were screened for organic vapors using a photo-ionization detector (Multi-Rae E-033). Organic vapors were not detected for any of the samples.

Upon completion of the borings, the boreholes were bailed (drilling mud removed) and groundwater level was measured. The boreholes were then backfilled with cement-bentonite grout to within approximately 2 feet from the ground surface and the balance was filled with soil. The grout was pumped from the bottom of the borehole up. Excess soil cuttings were placed in 55-gallon drums and hauled off site. The ground surface elevations at the exploration locations were estimated from a Google Earth and should be considered to be very approximate.

APPENDIX C

APPENDIX C

LABORATORY TESTS

INTRODUCTION

Representative undisturbed soil samples and bulk samples were carefully packaged in the field and sealed to prevent moisture loss. The samples were then transported to our Cypress office for examination and testing assignments. Laboratory tests were performed on selected representative samples as an aid in classifying the soils and to evaluate the physical properties of the soils affecting foundation design and construction procedures. Detailed descriptions of the laboratory tests are presented below under the appropriate test headings. Test results are presented on the boring logs and in the figures that follow.

MOISTURE CONTENT AND DRY DENSITY

Moisture content and dry density were determined from a number of the ring and Shelby tube samples. The samples were first trimmed to obtain volume and wet weight and then were dried in accordance with ASTM D 2216. After drying, the weight of each sample was measured, and moisture content and dry density were calculated. Moisture content and dry density values are presented on the boring logs in Appendix B.

COMPACTION TEST

A maximum dry density/optimum moisture test was performed in accordance with ASTM D 1557 on a representative bulk composite sample of the upper 4 feet of the on-site soils. The test results are graphically presented in Figure C-1 and summarized below.

BORING NO.	DEPTH (ft)	SOIL DESCRIPTION	OPTIMUM MOISTURE* (%)	MAXIMUM DRY DENSITY* (pcf)
RW-1, -2, -3	0-4	Silty Sand with Gravel (SM)	9.0	125

Note: * includes rock correction

EXPANSION INDEX

One expansion index test was performed in accordance with D 4829 on a composite bulk sample, representative of the soils in the upper 4 feet of the site. The test results are presented below:

BORING NO.	DEPTH (ft)	SOIL DESCRIPTION	EXPANSION INDEX
Composite RW-1, 2,3	0-4	Silty Sand with gravel (SM)	0

ATTERBERG LIMITS

Liquid and plastic limits were determined for selected samples in accordance with ASTM D 4318. The results of the Atterberg Limits tests are presented in Figure C-2.

GRAIN SIZE DISTRIBUTION

A total of 24 soil samples were dried, weighed, soaked in water until individual soil particles were separated, and then washed on the No. 200 sieve. That portion of the material retained on the No. 200 sieve was oven-dried and weighed to determine the percentage of the material passing the No. 200 sieve. For 16 of the samples, the retained material was run through a standard set of sieves in accordance with ASTM D 422. The weight of soil retained on each sieve was recorded and the total dry weight was calculated. The grain size distribution data from the full sieve analyses is presented in Figures C-3 through C-8. A summary of the percentages passing the No. 200 sieve (ASTM D1140) is presented below.

BORING NO.	DEPTH (ft)	SOIL DESCRIPTION	PERCENT PASSING No. 200 SIEVE
RW-1	32	Clayey Sand (SC)	49.8
	38	Gravelly Sand with Silt (SP-SM)	10.0
	43	Sand with Silt and Gravel (SW-SM)	9.8
RW-2	61	Sand with Silt and Gravel (SW-SM)	7.9
RW-3	8	Sand with Silt (SP-SM)	8.5
	10	Silty Sand (SM)	20.0
	15	Sand with Silt (SP-SM)	7.5
	20	Sand with Silt (SP-SM)	5.3

CONSOLIDATION

One-dimensional consolidation testing was performed on several undisturbed samples in accordance with ASTM D 2435. After trimming the ends, the samples were placed in the consolidometer and loaded to 0.25 or 0.4ksf. Thereafter, the samples were incrementally loaded to a maximum load of either 12.8 or 16 ksf. The samples were inundated at 0.4, or 0.5 ksf. Sample deformation was measured to 0.0001 inch. Rebound behavior was investigated by unloading the samples back to either 0.4 or 0.8 ksf. Results of the consolidation tests, in the form of percent consolidation versus log pressure, are presented in Figures C-9 to C-11.

DIRECT SHEAR

Direct shear tests were performed on remolded bulk samples and undisturbed samples in accordance with ASTM D 3080. The bulk sample was remolded to approximately 95 percent of maximum density (ASTM D1557). The samples were placed in the shear machine, and a normal load was applied. The samples were inundated, allowed to consolidate, and then were sheared to failure. The tests were repeated on additional test

specimens under increased normal loads. Shear stress and sample deformation were monitored throughout the test. The results of the direct shear tests are presented in Figures C-12 to C-19.

UNCOFINED COMPRESSION TESTS

Unconfined compression tests were performed on two samples of cohesive soils in accordance with ASTM D 2166. Detailed test results are presented in Figures C-20 and C-21.

UNCONSOLIDATED UNDRAINED TRIAXIAL TESTS

Unconsolidated undrained triaxial tests were performed on two samples of cohesive soils in accordance with ASTM D 2850. Detailed test results are presented in Figures C-22 and C-23.

SOIL CORROSIVITY

Soil corrosivity testing on samples from shallow depths was performed by AP Engineering and Testing. Test results are presented in Figure C-24 at the end of this appendix.

APPENDIX B

EXPLANATION OF BORING LOGS

VENICE DUAL FORCE MAIN
Los Angeles, California

MAJOR DIVISIONS		LTR	DESCRIPTION	MAJOR DIVISIONS		LTR	DESCRIPTION
COARSE GRAINED SOILS	GRAVEL	GW	Well-graded gravels or gravel-sand mixtures, little or no fines	FINE GRAINED SOILS	SILTS AND CLAYS LL<50	ML	Inorganic silts and very fine sand, rock flour, silty or clayey fine sands, or clayey silts with slight plasticity
		GP	Poorly-graded gravels or gravel-sand mixture, little or no fines			CL	Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays
		GM	Silty gravels, gravel-sand-silt mixtures			OL	Organic silts and organic silt-clays of low plasticity
		GC	Clayey gravels, gravel-sand-clay mixtures				
	SAND	SW	Well-graded sands or sand with gravel, little or no fines		SILTS AND CLAYS LL>50	MH	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts
		SP	Poorly-graded sands or sand with gravel, little or no fines			CH	Inorganic clays of hogh plasticity, fat clays
		SM	Silty sands, sand-silt mixtures			OH	Organic clays of medium to high plasticity
		SC	Clayey sands, sand-clay mixtures	HIGHLY ORGANIC SOILS		PT	Peat and other highly organic soils

SAMPLE COLUMN SYMBOLS

- Standard penetration test (SPT) sample
- Shelby tube sample
- Modified California split spoon sample
- Bulk sample
- P — Piston sample
- Continuous soil or rock core
- NR — No recovery

BLOWS/FOOT - Summation of blow counts for deepest 12 inches is sampling interval
RQD% - Rock quality designation in percent

DESCRIPTION COLUMN SYMBOLS

- Dashed lines separating soil strata represent inferred boundaries between sampled intervals or no recovery intervals and may be distinct or gradual transitions
- Solid lines represent distinct or gradual boundaries observed within sampled intervals
- Description right of bracket symbol represents soil conditions within the depth interval defined by the bracket length
- Description right of arrow symbol represents soil conditions to the next deeper boundary line unless otherwise noted
- Water level at time of drilling
- Water level after at least 12 hours from time of drilling

LABORATORY TEST ABBREVIATIONS

ATT	Atterberg Limits	CORR	Corrosion	S	Grain Size Analysis
COLL	Collapse Potential	DS	Direct Shear	SE	Sand Equivalent
COMP	Compaction	EI	Expansion Index	SG	Specific Gravity
CON	Consolidation	OC	Organic Content	TX	Triaxial Test
R	R-Value	PERM	Permeability	UC	Unconfined Compression Test
H	Hydrometer Test			#200	No. 200 Wash Sieve Analysis

NOTES

1. Soil descriptions are in accordance with the USCS as set forth by ASTM D2488 "Standard Practice for Description and Identification Soil (Visual-Manual Procedure)."
2. Soil color described according to Munsell Soil Color Chart. Rock color described according to Munsell Rock-Color Chart
3. Soil descriptions in these borings are generalized representations and based upon visual classification of cuttings and/or samples during drilling. Descriptions and related information in these borings depict subsurface conditions at the specific location and at the time of drilling only. Soil conditions at other locations may differ from conditions observed at the boring locations. Also, soil and groundwater conditions may change with time at these locations.

Los Angeles, California 90015

August 20, 2015

1.0 Introduction: GeoKinetics has completed a subsurface methane gas investigation at the proposed Venice Auxiliary Pumping Plant located at 133 Hurricane Street, in the City of Los Angeles. The location of the subject property is shown in Figure 1 while a recent aerial photograph of the site is provided as Figure 2. We understand that the proposed auxiliary pumping plant will consist of a wet well / valve vault, an electrical building and a diversion structure on the approximate 7,850 square foot property. The subject property is located in the Playa Del Rey Oil Field as it has been mapped by the California Department of Conservation, Division of Oil, Gas & Geothermal Resources (DOGGR). No oil wells are shown to exist at the property based upon our review of the DOGGR oil field map. The closest mapped oil well (Allied Petroleum Corp., "Rawco – Woodford", #1) is located approximately 55 feet southwest of the subject property. As a result, it is within a Methane Zone designated by LADBS. It will therefore be necessary to incorporate methane gas mitigation measures into the design of the proposed structures in accordance with LADBS requirements

Under the current building code, the nature and extent of the required mitigation measures are partially dependent upon the concentration and pressure of any methane gas that may be present at the site. The current investigation has been performed for the purpose of documenting the concentration and pressure of methane gas in the subsurface of the subject property such that appropriate mitigative improvements can be specified. This report presents the results of the subsurface gas investigation as well as associated methane mitigation recommendations in accordance with typical LADBS requirements.

2.0 Background: The presence of methane gas in the subsurface is common within former oil production areas and other locations where organic material - such as grass, leaves, wood, manure, etc. - are present in the soil. Biogenic methane is generated by the bacteriological digestion, or biodegradation, of organic matter in the absence of oxygen. Methane of thermogenic or petrogenic origin may also be present in surficial soils as a result of its upward migration from deeper oil and gas bearing zones. Our experience indicates methane gas is common and can be found in the soil at a relatively high percentage of building sites in southern California. Methane is not toxic, however it is combustible and potentially explosive at concentrations above 55,000 ppm in the presence of oxygen. This concentration is referred to as its Lower Explosive Level or LEL. Methane is lighter than air and therefore has a natural tendency to rise to the ground surface where it typically dissipates into the atmosphere. The presence of non-pressurized methane at shallow depths beneath the ground surface is normally not problematic. The rates at which the methane is generated and/or migrates towards the ground surface are slow enough such that the gas dissipates naturally under normal circumstances. However, as methane migrates to the ground surface, the

potential exists for its accumulation beneath slab-on-grade foundation systems or other relatively impermeable ground coverings. If the gas accumulates to high concentrations, and becomes pressurized, and a crack or other penetration is present in the floor slab of the structure, detectable levels of methane may enter the interior of the building. Improvements - such as sub-slab vent lines or gas membranes - are generally required by LADBS as a precautionary measure for new structures at Methane Zone sites.

3.0 Field Investigation: The field work associated with the methane gas investigation at the subject property included the installation and monitoring of five (5) multi-stage subsurface gas probes. The locations of these gas probes are shown in Figure 2. The subsurface gas probes were installed on August 6th, 2015 and they were subsequently monitored on August 7th and 11th, 2015. The gas probes were installed using 6" hollow stem auger drilling equipment. A schematic illustrating the general configuration of the gas probes is provided as Figure 3. The LADBS guidelines require that individual sampling tips be installed at depths of 5, 10, and 20 feet below the lowest floor level of the proposed structures. However, based on the known groundwater depth of approximately 8 feet bgs, probes were proposed to be installed on site at depths of 2, 5 and 7 feet bgs. Per LADBS guidelines, five shallow probes would be installed at a depth of 5' bgs and then two deeper probes would be installed at the two locations with the highest methane readings. However, in order to save time and reduce costs, all five borings were advanced to 8' bgs and probe tips were installed at 2, 5 and 7' bgs in each of the five borings. All five borings were logged in the field under the supervision of a registered engineering geologist. Copies of the boring logs for this project are included as Attachment A for your reference. As indicated, the upper four to five feet primarily consisted of moist fine grained sands. Clay, silty-clay and sandy estuarine deposits were noted just below the fine grain sands in each boring.

The sampling tips of the current installation were embedded within a 12-inch interval of washed Monterey #3 sand. Bentonite clay seals were placed above and below each sand interval in order to isolate the gas sampling tips. Gas tight quick connect fittings were installed on the ends of the polyethylene tubing at the ground surface in order to seal the probes between monitoring events. Flush-mounted vaults were installed at the ground surface to protect the installations.

As discussed previously, the installations were monitored on August 7th and 11th, 2015. All monitoring was performed during periods of falling barometric pressure. The subsurface gas pressure relative to atmospheric, and the concentrations of methane, oxygen, and carbon dioxide, were measured in the subsurface probes during each monitoring event. The monitoring equipment that was utilized and the associated detection limits, or resolutions, are summarized in Table 1. As indicated, subsurface gas pressures were

measured to the nearest 0.05 inches of water prior to each sampling event using a Magnahelic gauge while the barometric pressure was measured and recorded to the nearest 0.1 inches of mercury using a digital barometer. The gas probe methane, oxygen, and carbon dioxide concentrations were measured in the field using a portable, methane specific, LandTec GEM2000-Plus infra-red gas analyzer. A volume of gas equivalent to approximately ten times that of the ¼-inch diameter polyethylene gas probe tube was extracted through the LandTec GEM2000-Plus during the monitoring process. Steady state readings were generally obtained after approximately two tubing volumes of gas had been extracted. The highest methane reading displayed in each instance was recorded. The LandTec GEM2000-Plus was calibrated at the beginning and the end of each day of monitoring using a certified mixture of 15% methane, 15% carbon dioxide, and 70% nitrogen calibration gas (Note: all gas concentrations referred to in this report are on a volumetric basis). A Photovac Flame Ionization Detector (FID) was used to confirm combustible gas levels at selected probes where sufficient oxygen was present in the probe to operate the FID. The gas levels measured with both detectors were found to be consistent. Combustible gas concentrations in excess of 450 ppm were not detected with the FID.

Ambient gas levels in the air four feet above the ground surface were recorded at the site periodically during the monitoring. In each instance, the measured gas level fell within the following range:

Gas	Measured Range
Methane	<0.1%
Carbon Dioxide	<0.1%
Oxygen	20.8% – 20.9%

4.0 Results: The pressures and concentrations measured in each of the subsurface gas probes during the monitoring events are summarized in Table 2. As indicated, three of the 7' deep probe tips were flooded with water during the monitoring events. Also as indicated, the highest methane gas detection on site was 1,000 ppm (0.1%) at 5 feet bgs at probe P-5. Methane gas was not detected at any of the other gas probe installations. The site FID readings ranged from 0 to 449 ppm for the probes with enough oxygen to record a reading. This is consistent with the LandTec GEM2000-Plus readings.

The soil gas pressures measured in the gas probes range from 0.00 to 0.50 inches of water. This pressure range is normal and consistent with normal

barometric variations. There was no indication of elevated soil gas pressures associated with methane generation or migration.

The concentration of oxygen in the atmosphere at sea level is approximately 21%. The subsurface oxygen levels were found to be slightly to moderately depressed below typical atmospheric levels at each of the gas probe installations. The lowest subsurface oxygen level recorded at the site was 2.5% while the average oxygen concentration measured in the gas probes was approximately 14.6%. The average concentration of carbon dioxide in the atmosphere at sea level is approximately 0.03%. Subsurface carbon dioxide levels were slightly to moderately elevated above typical atmospheric levels in each of the gas probes. The highest carbon dioxide concentration measured at the site was 3.2% while the average carbon dioxide concentration measured in the gas probes was approximately 1.3%. The slightly to moderately depressed subsurface oxygen levels and slightly to moderately elevated carbon dioxide levels suggest residual organic matter entrained within the near surface soils is being biodegraded under aerobic conditions.

Based upon the measured methane levels and the corresponding soil gas pressures, we conclude the property should be classified as a Level II site with a Design Methane Pressure of #2" of water in accordance with LADBS guidelines. A copy of the LADBS methane testing compliance form for this project is included as Attachment B for your reference.

As discussed previously, the property is shown to be located within a Methane Zone. The following primary methane mitigation measures are typically required by LADBS for new Level II slab-on-grade structures within the methane zone:

1. **Sub-Slab Vent System:** A series of perforated vent lines and an associated 2" thick gravel blanket must be installed beneath the floor slab of the proposed structure. The perforated vent lines are connected to solid vent piping that extends through the walls or pipe chases of the building to outlets above the roof line. A dewatering system (sump and pump) must be installed if the design high groundwater level for the project is not at least one foot below the lowest vent piping elevation. A dewatering system is not necessary for on-grade structures for this project. However, structures that extend below approximately 5’ bgs will likely need either a dewatering system, or be constructed hydrostatically. If the hydrostatic option is selected, a modification from LADBS will likely be required in order to remove the sub-slab venting system requirement.

2. **Impervious Membrane:** A continuous gas membrane is required below the floor slab of the structures. This membrane must be sealed against footings, pilings, and utilities to form a gas-tight barrier beneath the buildings.

3. **Utility Trench Dams:** A section of impervious backfill consisting of compacted native soil or sand / cement slurry must be installed in utility trenches that extend beneath the perimeter of the buildings in order to prevent methane gas from migrating beneath the structure through sand bedding or backfill.

4. **Conduit Seals:** Gas tight seals must be installed on all conduits (e.g. electrical, cable T.V., telephone, etc.) that extend to the interior of the structure. The purpose of these seals is to prevent methane gas from entering subsurface cracks or discontinuities in the conduits and subsequently migrating to the interior of the buildings.

There are exceptions in the City Methane Ordinance (Ordinance No. 175790) that allow some of the requirements outlined above to be omitted, or modified, under certain conditions. These possible exceptions should be considered as the building plans are developed in order to determine the specific mitigative measures that will be required for the project.

5.0 Closing: This investigation has been performed with the degree of skill and care ordinarily exercised by engineers practicing in this, and similar, localities. No other warranty, expressed or implied, is given regarding the conclusions or professional opinions presented in this report. The scope of this report is limited to the matters expressly covered herein. This report is presented for the sole use of the Geotechnical Engineering Group and may not be relied upon by any other party without written authorization from GeoKinetics. All recommendations, findings, and conclusions presented in this report are based upon facts and circumstances as they existed at the time this report was prepared. A change in any fact or circumstance upon which this report is based may necessitate re-evaluation and/or modification of the recommendations, findings, and conclusions presented herein. Due to the nature of this type of investigation, uncertainty exists with respect to the subsurface conditions that are present between boring / sampling locations. The subsurface methane concentrations at the site could vary over time and may change in response to site modifications. The methane levels identified in this report represent the concentrations that were measured at the time of the

current investigation. Higher or lower concentrations could occur in the future. If the level of inherent uncertainty is unacceptable, additional sampling and/or testing should be considered.

We hope this information is helpful to you. Please do not hesitate to contact the undersigned if you have any questions or comments.

Sincerely,
GEOKINETICS, INC.

Methane Gas Investigation Compliance Certificate

FORM 1 - CERTIFICATE OF COMPLIANCE FOR METHANE TEST DATA

Part 1: Certification Sheet

Site: Venice Auxiliary Pumping Station Project

Address: 133 East Hurricane Street, Los Angeles, California.

Legal Description: APN # 4225008904

Building Use: Auxiliary Pump Station

Name of Engineer:	Kevin J. Lea GeoKinetics	**Registered Civil / Soil Engineer Stamp:**
Mailing Address:	77 Bunsen Irvine, CA 92618	
Telephone:	(949) 502-5353	
Testing Laboratory:	GeoKinetics License # 10234	

REGISTERED PROFESSIONAL ENGINEER
KEVIN J. LEA
NO. C- 67844
EXP. 6-30-17
CIVIL
STATE OF CALIFORNIA

I hereby certify that I have tested the above site for the purpose of methane mitigation, and that all procedures were conducted by a City of Los Angeles licensed testing agency in conformity with the requirements of the LADBS Information Bulletin P/BC 2002-101. Where the inspection and testing of all or part of the work above is delegated, full responsibility shall be assumed by the licensed engineer or geologist whose signature is affixed thereon.

Signed: _____ **Date:** 8-20-15

Required Data:

- Project is in a *METHANE ZONE*
- Depth to ground water observed during testing was: 7-8 feet below existing ground surface.
- Depth of Historical High Ground Water Table Elevation* is ~5 ft below existing ground surface.
- Design Methane Concentration**: 1,000 parts per million in volume (ppmv).
- Design Methane Pressure***: ≤ 2 inches of water column.
- Methane Design Level: II

De-watering:

- De-watering is Required for all construction below approximately 5' bgs. This condition can be potentially removed using a hydrostatic design under LADBS modification.
- Pump discharge rate N/A gallons per minute.
- Reference geology or soil report: N/A

Additional Investigation:

- Additional investigation was Not conducted.

Latest Grading on Site:

- Date of last grading on site was: Years ago
- Explanation of the effect on soil gas survey results by grading operations: N/A
- Building Excavation: Not Yet Initiated

Notes:

* Historical High Ground Water Table Elevation Shall mean the highest recorded elevation of ground water based on historical records and field investigations as determined by the engineer for the methane mitigation system.

** Design Methane Concentration shall mean the highest recorded measured methane concentration from either shallow soil gas test or any gas probe set on the site.

*** Design Methane Pressure shall mean the highest total pressure measured from any Gas Probe Set on the site.

As a covered entity under Title II of the Americans with Disabilities Act, the City of Los Angeles does not discriminate on the basis of disability and, upon request, will provide reasonable accommodation to ensure equal access to its programs, services and activities. For efficient handling of information internally and in the internet, conversion to this new format of code related and administrative information bulletins including MGD and RGA that were previously issued will allow flexibility and timely distribution of information to the public.

Hydrology Technical Memorandum

Watearth™
Water Resources + Green Infrastructure

HYDROLOGY TECHNICAL MEMORANDUM

Project: **Los Angeles Venice Auxiliary Pumping Plant EIR**
Client: ICF International/City of Los Angeles
Prepared By: Jennifer J. Walker, P.E., D.WRE, CFM, QSD
Date: 8-25-2016
Purpose: Memorandum of Hydrology Modeling Results

Note: Draft memorandum released under the authority of Jennifer J. Walker, P.E. (C77079), D.WRE, CFM on 8/25/2016 and should not be used for design or construction.

This memorandum documents hydrologic, hydraulic, water quality, and Low Impact Development (LID) modeling results for the construction of the Los Angeles Venice Auxiliary Pumping Plant (VAPP). The project is anticipated to include post-construction stormwater Best Management Practices (BMPs) and Low Impact Development (LID) features. Because detailed design has not been completed, hydrologic, hydraulic, and LID analyses are based on the general concept and layouts provided by the City and the design engineer, Arcadis, and described in the Venice Auxiliary Pumping Plant proposal project description and Preliminary Design Report (PDR). A hydraulic analysis of the Grand Canal to evaluate potential for impacts related to the temporary cofferdam during the construction phase is also included based on available data. Items excluded from the Environmental Impacts Report (EIR) as part of the Initial Study (IS) are not discussed in detail in this technical memorandum.

In accordance with the City of Los Angeles *Developed Best Management Practices Handbook, Low Impact Development Manual, Part B Planning Activities*, 4th Edition, published June 2011 (*LID Manual*), several stormwater Best Management Practices (BMPs) alternatives are analyzed as a post-construction water quality and hydrologic treatment measure for development of the VAPP site. As discussed below, due to low saturated hydraulic conductivity and infiltration rates of soils at the site, shallow depths to seasonally high groundwater, and potential for liquefaction, design modifications are required and the use of lined bioretention with an underdrain or a planter box is assumed.

Alternative 1 mitigates post-construction hydrologic and water quality impacts from the VAPP site using lined bioretention with an underdrain, while Alternative 2 uses a combination of a planter box and lined bioretention. The potential use of vegetated swales was also evaluated; however, this alternative is not included in this memorandum as it resulted in water quality and hydrologic impacts from the VAPP site.

While the final design may include use of a different LID feature or water quality and hydrology treatment, it is assumed that these will be designed to meet or exceed the performance of the LID features documented in this memorandum. Additionally, modifications to the geometric configurations and layouts of the evaluated LID alternatives may be made during the final design provided the same performance is achieved.

The goals established for this project include:

- ✓ Meet City of Los Angeles LID and stormwater treatment criteria;
- ✓ Mitigate increased runoff from the VAPP site using LID and reduce proposed peak flows in the Grand Canal to existing conditions levels;

- ✓ Mitigate increased pollutant loads from the VAPP site using LID and reduce pollutant loads in the Grand Canal to existing conditions levels;
- ✓ No adverse impacts to 100-year water surface elevations (WSELs) or increased flooding risk associated with construction of the proposed cofferdam or diversion structure during construction.

EXISTING CONDITIONS

Existing conditions for the project are described based on evaluation of prior reports, available data, and results of the site reconnaissance. As shown in Exhibit 1, the proposed VAPP site is located on the existing vacant lot at the northeast corner of Hurricane Street and Canal Court, across and immediately north of the existing Venice Pumping Plant (VPP). For purposes of the Environmental Impacts Results (EIR), the project consists of three lots in the vicinity of the existing VPP. In addition to the VAPP site, there are two possible staging areas: 1) adjacent to the existing VPP at the intersection of Canal Court and Hurricane Street and 2) across the Grand Canal from the proposed VAPP site, both on vacant land. The project is located within the Venice Community Planning Area and Council District 11, as well as within the Venice Coastal Zone Specific Plan area (Appendix Y). Refer to Exhibits 2 and 4 for an aerial and topographic view of the site, the existing VPP, and the two possible staging areas. The recently constructed VDFM is shown in Appendix F.

The VAPP Project Site is currently vacant and a gravel/earthen lot with relatively flat slopes. The impervious cover is zero-percent (Exhibit 2). Similarly, the two possible staging areas are also currently vacant with zero-percent impervious cover. The staging area located at the intersection of Canal Court and Hurricane Street is relatively flat and consists of bare earth with little vegetation. The staging area across the Grand Canal from the VAPP site includes bare soil, existing infrastructure (concrete pavement, stairway/railing, and pipes) and is partially vegetated. The vegetation is mostly native vegetation within the intertidal zone and non-native above the intertidal zone. Land use of the area surrounding the Project Site is considered Residential/Medium Residential (Exhibit 7). The existing peak flows from the area contributing to the existing outfall at Hurricane Street will not increase in proposed conditions as they will be mitigated using BMPs.

While all three lots are addressed for construction-phase items, only the VAPP site is included in the pre- and post-construction hydrologic and water quality analyses.

Existing conditions are discussed in the sections below for the following categories:

- Surface Water Quality
- Hydrology
- Hydraulics
- Flooding and Hazards

Surface Water Quality

The Project Site is currently vacant and land cover consists primarily dirt and gravel, with an existing impervious cover of zero-percent (Exhibit 2). Photos are included in Appendix O. Land use around the site includes a mix of land use types and is generally classified as Residential/Medium Residential (Exhibit 7). The two potential staging areas appear to have similar land use as the VAPP site.

The existing VAPP site does not include water quality or stormwater controls, such as stormwater Best Management Practices (BMPs), Low Impact Development (LID) features, or hydromodification management facilities. Additionally, stormwater detention and other flood control features are also not present on-site. Instead, the existing site manages rainfall and stormwater runoff by overland sheet flow towards the Venice Grand Canal or to the off-site storm drain system at Hurricane Street.

Typical Pollutants from Project Site

Stormwater runoff from the existing site is typical of an undeveloped area, which typically includes low levels of pollutants. Total Suspended Solids (TSS) and Chemical Oxygen Demand (COD) are common in vacant or open areas. Foot traffic and construction pollutants and trash are likely due to the upcoming development of the VAPP and surrounding neighborhood runoff may also contribute to the present on-site pollutants.

Additionally, nutrients from fertilizers as well as herbicides and pesticides associated with landscape maintenance are likely to be present in stormwater runoff from the vicinity into the Grand Canal, as a photo shows from the site reconnaissance in Appendix O. In addition, as shown in the photos included in Appendix O, many of the drainage inlets in roadways adjacent to the site include screens or grates to prevent or limit trash from entering the storm drain system and discharging to the receiving water (Venice Grand Canal). Due to urban runoff and human activities around the Venice Grand Canal shoreline, pollutants such as Fecal Coliform bacteria are expected to be present in the stormwater runoff into the Grand Canal.

Table 1 summarizes typical pollutants of concern based on land use. The majority of the pollutants are from the February 2014 County of Los Angeles Department of Public Works *Low Impact Development Standards Manual*. Also included in this table are other pollutants that the U.S. EPA recognizes to be typically associated with land use present on the Project Site.

TABLE 1: POLLUTANTS OF CONCERN BY LAND USE

Land Use	Pollutants of Concern

[1] Adapted from Table A-3 of the *Technical Manual for Stormwater Best Management Practices in the County of Los Angeles* (February 2004) and the Southern California Coastal Water Research Project Land Use Specific Storm Water Monitoring Data. X= exceedance of "standard" by observed median/average concentration; blank = no exceedance of "standard" by observed median/average concentration.
[2] Derived from Table 11 of the 2012 Los Angeles County MS4 Permit (page 104).
[3] Critical facilities include automobile dismantling (SIC 50xx), automobile repair (SIC 75xx), metal fabrication (SIC 34xx), motor freight (SIC 42xx), automobile dealerships (SIC 55xx), chemical manufacturing (SIC 28xx), and machinery manufacturing (SIC 35xx).
[4] No available date to determine if these pollutants of concern originate from this land use. Pollutant is assumed to be produced by this land use unless otherwise proven by the project applicant.
[5] Based on 2006 U.S. EPA *Guide to Stormwater Pollutant Concentrations*.

Pollutants of Concern Based on Receiving Water Impairment

The *Clean Water Act* (CWA) requires that states adopt water quality standards for receiving waters. Water quality standards designate beneficial uses for the receiving water and include criteria required to support those beneficial uses. Water quality criteria are either narrative statements related to the quality of water to support a particular use or maximum concentrations of levels of pollutants (i.e., bacteria, etc.). As part of the CWA, when monitoring data indicates

that a pollutant is exceeded, the receiving water is classified as impaired and placed on the *CWA Section 303(d) List of Water Quality Limited Segments Requiring TMDLs* (303(d) List). A Total Maximum Daily Load (TMDL) is then developed for the pollutant(s) causing the impairment. The purpose of the TMDL is to limit the amount of pollutant(s) discharged to the receiving water from all sources (i.e., stormwater runoff, wastewater, agriculture).

There are several pollutants of concern related to the receiving body of water and include those pollutants with a developed TMDL requirement, other pollutants listed on the 303(d) List, and pollutants of concern for the Ballona Creek watershed management area based on the *Ballona Estuary, & Sepelveda Channel Bacteria TMDL, Coordinated Monitoring Plan* from the Los Angeles County (Appendix M). The project is located adjacent to the Grand Canal just upstream of the confluence with the Ballona Lagoon in the Ballona Creek watershed. Table 2 lists the pollutants from the EPA 303(d) list for Ballona Creek and includes pollutants that have a completed TMDL, pollutants that require development of a TMDL, and pollutants that are being addressed by actions other than a TMDL.

TABLE 2: BALLONA CREEK 303(d) LIST

Pollutant	Pollutant Category	Potential Source	Source Category
Cadmium (sediment)	Metals/Metalloids	Point Source	Unspecified Point Source
Cadmium (sediment)	Metals/Metalloids	Nonpoint Source	Unspecified Nonpoint Source

Viruses (enteric)	Pathogens	Nonpoint Source	Unspecified Nonpoint Source
Zinc	Metals/Metalloids	Source Unknown	Source Unknown

Appendix Z includes a map obtained from the County of Los Angeles *Low Impact Development Handbook* that illustrates the TMDLs that are in effect for Los Angeles County as of October 2013. Multiple TMDLs are in effect for the Ballona Creek Watershed for the following pollutants:

- Metals
- Toxics
- Trash
- Bacteria

Table 3 and Appendix Z list the pollutants of concern for the Ballona Creek watershed management area, within which the Project Site falls.

TABLE 3: TIER 3 POLLUTANTS OF CONCERN FOR THE BALLONA CREEK WATERSHED MANAGEMENT AREA

Parameter	Parameter

E. coli Bacteria[1]	Copper, Total Recoverable
Total Coliform Bacteria[1]	Lead, Total Recoverable
Fecal Coliform Bacteria[1]	Mercury, Total Recoverable
Enterococcus Bacteria[1]	Selenium, Total Recoverable

[1]Apply only to discharges to the estuary and the ocean.

Baseline Sampling Data

The City of Los Angeles requested water quality sampling on June 5, 2015 before the project began. Samples were collected in the morning and early afternoon on July 1, 2015. The following water quality parameters were determined for the baseline: pH, temperature, Dissolved Oxygen (DO), turbidity, and Total Suspended Solids (TSS). A visual assessment for any floating hydrocarbons was also performed. Samples were obtained from the Grand Canal at three locations near the project area: Site 1 was at the construction site at a culvert on Hurricane Street, Site 2 was at the VAPP station at the upstream incoming tide, and Site 3 was at the VAPP station at the downstream outgoing tide.

The project areas were photographed during two field reconnaissance visits. On sampling day, there was a high tide at 10:21 AM (3.9 ft) and a low tide at 3:58 PM (-0.9 ft). Note that the datum was not specified in the sampling report. Site 2 was sampled at 10:04 AM and Site 3 was sampled at 1:35 PM. No anthropogenic particles or hydrocarbons were observed at any of the sites.

The TSS at Station 2 was 40 mg/L and at Station 3 was 51.2 mg/L. The complete results of this study are included in the Venice Auxiliary Pumping Plant (VAPP) Water Quality Sampling Report (Appendix K), including pH, Temperature, Dissolved Oxygen (DO), and Turbidity.

In addition to the project sampling, water quality samples were collected as part of the *Grand Canal West Bank Erosion Control Project* between May 29th and July 17th, 2015. Two stations, Galleon and Ballona/Grand, in the study were in proximity to the Project Site. The Galleon station is one block north of the Project Site, or approximately 225 ft. The Ballona/Grand station is located at the junction of the Grand Canal and Ballona Lagoon. The water quality parameters that were measured were DO, pH, temperature, TSS, turbidity and floatables. TSS at the Galleon station ranged from 4 to 17.8 mg/L during the sampling period. TSS at the Ballona/Grand station ranged from 14.3 to 42.5 mg/L, which is comparable to the project TSS sampling results. Complete water quality results from the Grand Canal West Bank Erosion Control Project are in Table 1 in Appendix AB.

Total Maximum Daily Loads

A total maximum daily load (TMDL) is a regulatory term in the *U.S. Clean Water Act* (CWA), describing the value of the maximum amount of a pollutant that may enter a water body while still meeting water quality standards. There are several listed TMDLs for the Ballona Creek area in Table 4 below, from the Los Angeles Region's *Basin Plan* (Appendix R). Among those listed are: trash, cadmium, copper, lead, selenium, zinc, chlordane, DDTs, Total PCBs, Total PAHs, E. coli bacteria, fecal coliform, *Enterococcus*, and total coliform. The loading capacities for each pollutant are:

TABLE 4: TMDLs For Ballona Creek

Pollutant	Loading Capacity (ug/L)
Trash	0
Total Recoverable Metals	
Copper	18
Lead	55
Selenium	5
Zinc	119
Toxic Pollutants (Sediment)	
Cadmium	1.2
Copper	34
Lead	46.7
Silver	1
Chlordane	0.5
DDT	1.58
Total PCBs	22.7
Total PAH	4,022
E. Coli (MPN)	126
Fecal Coliform (MPN)	200

Summary

Table 5 summaries potential pollutants from the site based on land use along with pollutants of concern from the various sources described above and Table 6 summarizes pollutants of concern specific to Ballona Creek.

TABLE 5: SUMMARY OF POTENTIAL POLLUTANTS AND POLLUTANTS[1] OF CONCERN

Nutrients	Metals	Organics	Other	Pathogens	Sediment/Solids	Inorganics
Algae	Aluminum	BOD	Chloride	Coliform Bacteria	Suspended Solids	Cyanide
Ammonia	Cadmium	COD	Hydrocarbons	Viruses	Total Dissolved Solids	
Organic Nitrogen	Chromium	Polycyclic Aromatic Hydrocarbons	pH		Turbidity	
Total Nitrogen	Copper	Polychlorinated biphenyls	Sulfate			
Total Phosphorous	Lead		Trash			
	Mercury		Chlordane			
	Selenium		DDT			
	Silver					
	Zinc					

[1] Pollutants from the 2010 U.S. EPA approved 303(d) list.

Hydrology

Elevations within the VAPP site range from a low of approximately four feet (ft) in the southwestern portion of the site to a high of approximately six ft near the center of the site (Exhibit 4). The vertical datum for the topographic data is North American Vertical Datum (NAVD) 88. Off-site flows into or through the VAPP site are minimal. The stormwater runoff currently flows from the site and adjacent lots into an existing storm drain inlet at the end of Hurricane Street, which discharges into the Grand Canal. The area surrounding the VAPP is relatively low, only reaching heights of five feet, as shown in Exhibit 4. The approximate elevation of the bank area is five feet and gradually slopes towards the Grand Canal eventually reaching one-foot above mean sea level. Overland flow for the VAPP site is generally southwest to northeast.

The two staging areas also appear to drain to the Grand Canal or Ballona Lagoon. The possible staging area located at the intersection of Canal Court and Hurricane Street partially drains to the existing storm drain inlet at Hurricane Street and Esplanade, but also appears to sheet flow to the Ballona Lagoon just downstream of the confluence of the Grand Canal with the Ballona Lagoon (Exhibit 4). The additional optional construction staging area across the Grand Canal appears to sheet flow into the Grand Canal system (Exhibit 4). The Project Site is located a significant distance from existing stormwater spreading grounds shown in Exhibit 10.

The Grand Canal is located directly adjacent to the VAPP site and overland flow in the vicinity is generally east towards the canal system. The confluence of the Ballona Lagoon with the Venice Grand Canal is located approximately 150 ft southeast of the VAPP site (Exhibit 16). The construction staging area is adjacent to the Venice Pumping Plant along the Ballona Lagoon and an additional optional construction staging area is immediately across the Grand Canal from the VAPP site (Exhibit 2). Extreme event stormwater runoff that exceeds capacity of the on-site and public storm drain systems flows towards Ballona Lagoon. The Ballona Lagoon flows to the Marina Del Rey harbor through a tide gate.

The existing, undeveloped VAPP site as well as the two possible staging areas do not include water quality or stormwater controls, such as stormwater BMPs, LID features, or hydromodification management facilities. Additionally, stormwater detention and other flood control features were not observed on-site. Instead, the existing site manages rainfall and stormwater runoff via overland flow into the adjacent roadway, drain inlets, and underground storm drain systems, which discharge into the Grand Canal adjacent to the site.

As discussed previously, impervious cover at the currently vacant VAPP site, which is a gravel lot, is zero-percent (Exhibit 2) and stormwater management and runoff is typical of urbanized runoff from other sites within the vicinity. Land use of the adjacent lots consists of buildings, driveways, and sidewalks and is generally considered Residential/Medium Residential (Exhibit 7); however, the two possible staging areas are also currently vacant and zero-percent impervious cover.

The drainage areas and associated discharge locations of the VAPP site and two possible staging areas are not expected to change due to the project. As development is not proposed on the two

staging areas, there is no increase in peak flows or runoff volumes between existing and proposed conditions. As such, these two staging areas are included in the overall Grand Canal watershed modeling, but are not modeled separately. The drainage area to the existing 24-in outfall at the Grand Canal is approximately 5 ac (Exhibit 6B) and the estimated existing peak flow is 3 cfs for the 25-year event, based on the Los Angeles County *Hydrology Manual*. The capacity of the 24-in RCP is approximately 16 cfs, based on an assumed slope of 0.5-percent, which is sufficient.

As discussed in the hydrology section, existing conditions peak discharges from the VAPP site are estimated at 72.9 cubic feet per second (cfs), 165.7 cfs, and 263.8 cfs for the two-year, 24-hour, ten-year, 24-hour, and 100-year, 24-hour design storm events, respectively. However, because of the high level of impervious cover of 75% in proposed conditions, peak flows and runoff volumes are significantly higher from the same site without mitigation than the existing undeveloped condition. The increases in peak flows for the two-year, ten-year, and 100-year storm events will be managed through the use of BMPs and therefore, changes to the existing storm drain are not proposed. While the proposed peak discharges may vary slightly depending on the selected alternative, the proposed peak discharges will be less than or equal to the existing peak discharges.

The water budget for the undeveloped VAPP site includes high amounts of infiltration and evapotranspiration due to the gravel and vacant area (pervious areas) with depressions and other low spots for temporary rainfall ponding. Stormwater runoff from the Project Site in existing, undeveloped conditions is estimated at 35.6 in (1.0 in/year [yr]), based on continuous simulation analysis of the period of record from 1970 – 2005. Table 6 in Appendix C includes the results for the project and additional details on runoff rates and modeling assumptions for existing conditions and the two LID alternatives.

While minimal erosion is expected from the majority of the VAPP site post-construction due to the high-level of impervious cover in proposed conditions, there is potential for erosion and sedimentation at the discharge location at the Grand Canal. As the two staging areas will be used only temporarily during construction, conditions at these two lots are expected to be similar between pre- and post-construction.

Hydraulics

From aerial photographs (Exhibit 2) and visual observations during site reconnaissance, the VAPP site and two staging areas drain via overland flow into the Grand Canal or into storm drain inlets and storm drain systems in the adjacent streets, which discharge into the Grand Canal. Stormwater runoff from the VAPP site and adjacent lots enters the conveyance system through the storm drain inlet at Hurricane Street and Esplanade. The outfall pipe from this inlet appears to be a 24-inch (in) Reinforced Concrete Pipe (RCP) with concrete wing walls and discharges into the Grand Canal. The drainage area to the outfall at the Grand Canal is approximately 5 acres (ac) as shown in Exhibit 6B and the estimated existing peak flow is 3 cfs for the 25-year event, which is based on the Los Angeles County *Hydrology Manual*. The capacity of the 24-in RCP is approximately 16 cfs, based on an assumed slope of 0.5-percent, which is sufficient.

The Grand Canal in the vicinity of the VAPP site and staging areas consists of an earthen channel with partially vegetated side slopes. Vegetation consists of densely planted native vegetation, sparsely planted areas, areas with volunteer plants/weeds, and bare earthen areas (Appendix O).

Marina Tidal Gates

The Ballona Lagoon and the Venice Grand Canal are bounded by two tidal gates; The Marina Tide Gates to the south and the Washington Blvd. Tide Gates to the north. The Ballona Lagoon abuts the Marina Tide Gates, southerly of the Project Site and the Venice Grand Canal. The Ballona Lagoon and the Venice Grand Canal conflux at the Venice Pumping Plant. The Venice Grand Canals extend north from the Venice Pumping Plant to the Washington Boulevard (Blvd) Tide Gates, and averages about 50 ft wide. The Ballona Lagoon and Venice Grand Canal are exposed to Pacific Ocean currents via the Marina Tidal Gates that connect to the Marina Del Rey Harbor and the Santa Monica Bay via tidal waters. Both Tidal Gates are automated and centrally controlled from the Venice Pumping Plant. They open during high and low tides for tidal flushing of the Ballona Lagoon and Venice Grand Canal. Based on the Department of Public Works, Bureau of Engineering Venice Tide Gates Engineering drawings (Appendix AD), there are five tide gates beneath Washington Blvd along the Venice Grand Canal. The dimension measured from the center of the lid when closed to the top of the frame is three feet for each gate.

The Grand Canal Conceptual Plan-Hydrology Plan (*Grand Canal Hydrology Plan*) prepared by Philip Williams Associates, Ltd. in October, 2007 included hydraulic modeling within the Environmental Fluid Dynamics Code model (Appendix G). According to the report, the tides in the Grand Canal vary between -1.3 ft and 0.9 ft mean sea level (MSL) from mid-April to mid-October. From mid-October to mid-April, the tidal range is between -1.3 ft MSL and 0.3 ft MSL. For the modeling performed in the *Grand Canal Hydrology Plan*, the minimum water level may be as low as the bottom elevations as the Grand Canal dries out at the lowest tides. However, we understand from City staff that the Grand Canal does not actually dry out during operational conditions. The maximum water level is determined by the Marina Del Rey tide gates' operational setting, as stated in the *Grand Canal Hydrology Plan*.

Dry mode for this model refers to the time-period between Mid-April to Mid-October where significant rainfall is unlikely and the gates are closed when the Marina water exceeds 2.25 ft MSL and the Marina water level is more than 0.25 ft higher than the Ballona Lagoon water level. Wet mode for this model refers to the time-period between mid-October to mid-April where significant rainfall is possible and the gates are closed when the Marina water level exceeds 0.0 ft MSL and the Marina water level is more than 0.25 ft higher than the Ballona Lagoon water level. The hydrology of the area examined by the *Grand Canal Hydrology Plan* was not the actual current condition because of the construction plans underway for the Marina Del Rey Tide Gates.

The variations of the tides according to the *Grand Canal Hydrology Plan* allows for almost a full meter's depth change according to the mean tidal changes. The water surface of the Grand Canal

is not discussed. The closest base flood elevation (BFE) to the Grand Canal is 9 ft, located in Marina Del Rey (Exhibit 3). In Marina Del Rey, the flood zone is AE. In the Pacific Ocean, the BFE from the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Map (FIRM) Panel (Exhibit 3) is 15 feet and is considered in the VE flood zone. According to FEMA, the VE flood zone is characterized as areas subjected to inundation by the one-percent annual chance flood event with additional hazards due to storm-induced velocity wave action.

A personal interview was conducted on October 12, 2015 with a representative of Mariposa Landscapes (email exchange with Luis Valenzuela included in Appendix N), the company contracted to perform manual tidal flushing. According to Mr. Valenzuela, to flush the Venice Canals, tide gates on the Washington Boulevard (Blvd) culverts are opened for two to six hours per day approximately twice per week. The day of the week varies due to changes in the tides. When the tide gates are open, high tide and low tide in the Grand Canal are dampened by 0.3 to 0.6 ft. During a 50-year design storm event, predicted water levels in the Grand Canal peak at 2.2 ft MSL and drain completely at the next low tide, per the *Grand Canal Hydrology Plan*.

Existing Venice Pumping Plant

The focus of the hydraulics analysis is on potential hydraulic impacts of the cofferdam in the Grand Canal. The pump stations and force mains are not evaluated as part of this study. From the Project Overview and Description (2015), the Venice Pumping Plant (VPP) is at risk for reaching maximum capacity during extreme wet weather events, as well as, being in need of maintenance. In order to offset this, an additional pipeline the Venice Dual Force Main (VDFM) is planned to help provide redundancy, to relieve capacity from the main pipeline, and to allow the main pipeline to be taken offline for required maintenance. The VAPP would serve as an additional pumping plant to supplement the flows required for the wastewaters to the discharge vault located two miles southeast of the existing VPP.

The existing VPP contains five 400-horsepower pumps designed to handle 18 million gallons per day at 100 feet total dynamic head each. The pumps require much needed maintenance as there have been times where two pumps have been out of service during heavy wet weather events (Project Overview, 2015). As a result, rental pumps have been brought in to help supplement pumping of flows during heavy wet weather events.

Flooding and Hazards

Flood Plain

As shown on Exhibit 3, the Project Site is located in Zone X within the regulatory 500-year flood plain of the Grand Canal. The Flood Insurance Rate Map (FIRM) Panel shown in the exhibit is 6037C1752F. These panels were updated September 26, 2008. Areas shown within the shaded Zone X are the areas between the limits of the base flood and the 0.2-percent annual chance, or 500-year floodplain. This means the area is classified as a moderate flood hazard area.

There is no flood plain or flood fill proposed as part of this project and no houses, buildings, or structures will be placed within the 100-year flood plain as a result of this project. However, a cofferdam and diversion structure will be constructed within the Grand Canal and will

temporarily partially obstruct flows within the Grand Canal. A hydraulic model was developed for the Grand Canal and these items are analyzed in the Hydraulic Analysis section below.

Tsunami, Seiche, and Mudflow

The Project Site is located within a tsunami hazard zone (Exhibit 11). The project is not located within a seiche or landslide/mudflow hazard zone. We understand that the design engineers (Arcadis) are responsible for designing the project; VAPP site, structures, and equipment; and structures within the Grand Canal will be designed to withstand possible tsunami hazards.

Sea Level Rise

The project will need to consider sea level rise as a flood risk and we understand that Arcadis is handling sea level rise and tsunami protection as part of the design process. The Venice, California area is expected to be exposed to the 100-year sea level rise risk based on information in the USGS and USC studies (see Appendix Q for the *Sea Level Rise Vulnerability Study* for the City of Los Angeles, prepared by the University of Southern California Sea Grant Program, 2013). The project has an expected life of 75 years and is expected to be exposed to risk from sea level rise. The project is also located near Ballona Lagoon which is classified as a major channel by the USC. Major water bodies are exposed to more flux in tides and may therefore have an increased risk of flooding during a 100-year flooding event. According to the Sea Level Rise Exposure Maps in Appendix Q, the VAPP is within the expected 100-year sea level rise area.

The issues related to sea level rise are more concerning in the short-term as opposed to the long-term, planning and preparation-wise. According to the California Coastal Commission *Report of Sea Level Rise*, August 12, 2015 (Appendix L), any climate induced increase in storm frequency and magnitude will induce short- term changes in sea level. Most flooding and erosion damage are due to storm surges and wind-driven waves. The most severe impacts tend to occur when a storm surge coincides with the high tide and periods of high sea level rise.

According to the *Report of Sea Level Rise*, if the frequency or intensity of storms changes as a result of climate change, the frequency of high sea level rise extremes will also change. If the frequency does not change, sea level rise will increase coastal exposure to storm-driven surge and high waves, magnifying impacts to coastal areas.

Subsidence may also play a role in sea level rise. Since sea level rise is equal to the change in absolute sea level minus the change in the height of solid earth surface, withdrawal of natural resources can lower land surface. Groundwater and natural gas withdrawal is of concern along the west coast of California. An increase in subsidence may also increase sea level rise without taking into account the various other factors that contribute to the causes of sea level rise, per the *Report of Sea Level Rise*.

Sea level rise is expected to occur by the Intergovernmental Panel on Climate Change (IPCC) (Appendix Q). With projections ranging from 18 centimeters (cm) (0.59 ft) at the lowest projection to 59 cm (1.94 ft) for the highest projection by the year 2100, the VAPP project should consider the possibility of each projection and occurrence of sea level rise to compare it

to the 75-year life expectancy of the completed VAPP project. The United States Geological Survey (USGS) has mapped out the inundation risk of the project. The project area could experience the effects of sea level rise if levels inundate at 200 centimeters. It must also be taken into to account the added risk due to the Grand Canal being part of the project. Therefore, a risk of inundation at 150 centimeters must be taken into account. The exhibits for the mapped inundation risks may be viewed in Appendix S.

According to the USC report on sea level rise, the beaches of Venice, California are already retreating. Natural sand nourishment has been declining since the 1960s and the area is vulnerable to flooding and inundation due to being at sea level.

Low Impact Development and Post-Construction Best Management

The nature of this project will require the use of post-construction BMPs in order to mitigate the stormwater runoff and maintain the water quality of the area according to the City of Los Angeles *LID Manual*. In the case of the VAPP site, the LID designs need to meet the standards set by the City of Los Angeles but will also need to meet the environmental standards of feasibility. Certain types of BMPs that are allowed to be used are not considered feasible due to the high groundwater levels and soil types present in the project area. There is also the potential for liquefaction that requires the design of the design of the BMP to withstand the risk of it. The soil type for the site is indicated in the Geotechnical Report prepared by the City of Los Angeles and dated December 14, 2015 (Appendix U) and the soil types for the vicinity are shown in Exhibit 8.

Exhibit 11 illustrates areas most susceptible to inundation due to tsunami. As shown in Exhibit 12, the project area is located within an area that is susceptible to liquefaction. Due to this, certain LID approaches for mitigation may not be suitable for the area or may require structural design modifications.

Groundwater levels are likely too high to use bioretention or bioinfiltration with an underdrain. With a combined surface storage and drain rock layer depth of approximately four ft plus a clearance of five ft below the bottom of the LID and seasonally high groundwater, the groundwater would need to be nine ft below natural ground, which seems much lower than the assumed depth of one ft above sea level from the geotechnical report. As stated in the geotechnical report (Appendix U), “Measured groundwater levels in the project area have generally varied between elevations of -2 to +4 feet of sea level. Groundwater levels beneath the site fluctuate as the result of seasonal variations and tidal fluctuations. Based on the available geotechnical data, a baseline groundwater elevation of one foot above sea level has been selected for the project.”

The site is located within 50 feet of a steep slope (20% or greater) along the Grand Canal bank shoreline, is prone to liquefaction geotechnical hazards, and the proposed landscaped area rates a categorization of 3 due to its size in accordance with Table 4.3 of the City’s *LID Manual*, making capture and use BMPs infeasible. Due to the infeasibility of capture and use BMPs, it is assumed that the final design will meet LID and water quality treatment requirements through

the use of BMPs. The best would be surface level LID approaches that simply filter water as opposed to emphasizing infiltration.

Bioinfiltration was considered as an alternative based on the feasibility checklist within the City's *LID Manual* and native soil infiltration rates in the project area, but was discarded because of the depth to seasonally high groundwater, which prohibits the required five- to ten-foot of clearance required between the bottom of infiltration BMPs and the depth to seasonally high groundwater to be achieved. Bioinfiltration is designed for partial infiltration of runoff and partial biotreatment. These features have an elevated underdrain above a gravel sump designed to facilitate infiltration and nitrification/denitrification.

This type of BMP can be used in areas where there is little to no hazard associated with infiltration where infiltration screening does not allow for infiltration BMPs due to low infiltration rates or high depths of fill soils. The surface soils of this area have a high depth of fill and a high groundwater level. The seasonal groundwater level makes this type of design difficult because of the fluctuating groundwater levels that can be higher than allowed by the City's criteria. The risk of liquefaction in this area may also require design modifications for this type of design.

Based on site constraints, the following were considered as potentially feasible alternatives and evaluated in the hydrologic and LID analysis described in the following section:

- Alternative 1 – lined bioretention with underdrain
- Alternative 2 - planter box (drains building) and lined bioretention with underdrain

The first alternative evaluated is lined bioretention with the use of an underdrain. The underdrain will be at the bottom of the gravel storage layer (drain rock) with zero offset height. This type of BMP design is a bioretention treatment control that is completely contained within an impermeable structure with an underdrain and does not allow for infiltration. With vertical, impermeable walls this type of BMP can be placed near structures or sidewalks with proper structural design. This type of design may be considered more feasible for the area due to the impermeable walls that would be more acceptable to the soils in the area and the risk of liquefaction. Additionally, the impermeable liner is needed to do the lack of clearance between the bottom of the LID and the depth to seasonally high groundwater.

The size of the Alternative 1 bioretention area would be 700 sq. ft. and 18 in deep within the proposed Pocket Park area, with a bottom saturated hydraulic conductivity of zero to simulate the liner. Due to geometric constraints associated with the proposed width of the park space, vertical walls (0:1 H:V side slopes) are assumed to achieve the required two-foot minimum bottom width and 18 in surface depth. While the proposed surface area of the lined bioretention exceeds the minimum requirement from the *LID Manual*, the larger size is needed to mitigate peak flows and water quality impacts from the VAPP site, as no infiltration occurs with this alternative. Details on modeling and results are discussed in the Hydrologic Analysis and Water Quality Analysis sections below.

The second alternative is the use of a planter box to drain the building and a 380 sq. ft. lined bioretention with an underdrain to drain the remainder of the VAPP site. The planter box is sized at 62 sq. ft. and 12 in deep. It would have an underdrain and hydraulic conductivity similar to the lined bioretention alternative. Planter boxes have impermeable walls and function similarly to bioretention facilities with underdrains; however, it would be situated adjacent to the building and capture stormwater runoff from the building roof. The configuration of the lined bioretention would be similar to Alternative 1. While the proposed combined surface areas exceed the minimum requirement from the *LID Manual*, the larger size is needed to mitigate peak flows and water quality impacts from the VAPP site, as no infiltration occurs with this alternative. Details on modeling and results are discussed in the Hydrologic Analysis and Water Quality Analysis sections below.

The proposed LID features are also planned to meet requirements in the City's *LID Manual*. Specifically, for Alternative 1, the required minimum BMP surface area of 277 square feet (sq. ft.) was calculated using the BMP Design Criteria in Table 4.5 in the handbook, based on a 2.5 in/hr infiltration rate, 48-hour surface drain down time, and a ponding depth of 1.5 feet (ft) for lined bioretention and vegetative swale alternatives. Using a ponding depth of 1.0 ft for a planter box for the building runoff area changes the minimum BMP surface area for the lined bioretention basin in Alternative 2 to 230 sq. ft. and the planter box minimum BMP surface area is 62 sq. ft. The goal of the LID features is to provide stormwater quality benefits and to more closely mimic undeveloped site hydrology. Refer to Exhibit 17 for the proposed LID layout alternatives of the project and note that sizes larger than the minimum are required to mitigate peak flow and water quality impacts from the VAPP site. A different LID feature could be used other than the alternatives that were analyzed, but the same performance must be achieved.

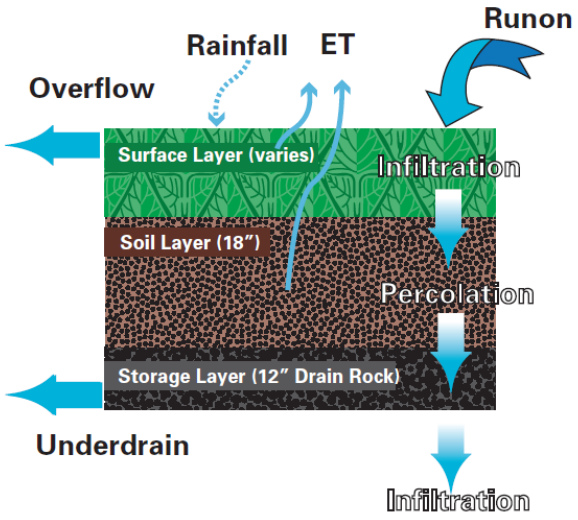
LID features are required to retain 100-percent of the stormwater quality design volume (SWQDv) on-site through a combination of infiltration, evapotranspiration, and stormwater harvest and use unless it is demonstrated that it is technically infeasible to do so. For this project, the SWQDv is approximately 1.0 in, which is the 85th-percentile, 24-hour event obtained from the City of Los Angeles 85th percentile precipitation isoheytal map for the Project Site location. The City of Los Angeles *LID Manual* specifies that the LID must be sized for at least the volume of water calculated using the recommended formula from the Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87 (1998) which determines the 85th percentile 24-hour runoff event and maximized capture stormwater volume for an area using a 48 to 72-hour drawdown time.

Alternatively, as stated in the *LID Manual*, the LID can be sized to accommodate the volume of annual runoff based on unit basin storage water quality volume and treat 80 percent or more volume as recommended in the *California Stormwater Best Management Practices Handbook – Industrial/Commercial* (2003), or it can be sized from a 0.75 inch storm event. This project will use a high removal efficiency biofiltration BMP within the park area sized to capture 1.5 times the runoff volume and meet the minimum sizing requirements in the LID Manual.

HYDROLOGIC ANALYSIS

The U.S. Environmental Protection Agency's (EPA)'s Storm Water Management Model (SWMM) 5.1 was utilized for the LID design storm and continuous simulation modeling in this project. The current version of SWMM includes LID controls and detailed analysis options not previously included in SWMM5. The SWMM model is also a publicly-available model. The SWMM model accounts for infiltration through various LID layers, evapotranspiration, infiltration into the native soil, and overflows and discharge from the LID facilities as illustrated in Figure 1.

Figure 1: LID Components and Processes Modeled in SWMM



Recent studies by the EPA cited in the report entitled *SUSTAIN – A Framework for Placement of Best Management Practices in Urban Watersheds to Protect Water Quality* found similar results for analysis of aggregated (lumped) LID controls in drainage sub-areas of 100 ac or more as compared to micro-drainage sub-areas for each lot and LID control (distributed approach). For a 128-acre drainage sub-area, the difference in peak flows between the aggregated and distributed approaches computed in the EPA study is four-percent. Similar positive findings with regards to the aggregated approach were also reported by the City of Portland's Bureau of Environmental Services in a paper entitled *Modeling Non-Directly Connected Impervious Areas in Dense Neighborhoods.*

Since the area of the VAPP site is approximately 0.18 ac and well under the threshold for using the aggregated method, the aggregated modeling approach was used for this project to increase modeling efficiencies even though Alternative 2 includes two different types of LID features. Whether one or multiple LID features are used in the final design to treat runoff from the entire VAPP site, peak flow rates are still expected to be within one-percent of those computed using

the distributed approach and runoff volumes are expected to be within approximately three-percent.

The VAPP Project Site is located in the Santa Monica Beach-Frontal Santa Monica Bay watershed (Exhibit 5) and within the Santa Monica groundwater Basin (Exhibit 9). Exhibit 6A illustrates the three drainage areas used in the hydrologic modeling along with the locations of nodes in the SWMM model. The modeled drainage areas include: North of Washington, South of Washington, and Site (VAPP Site). Both of the staging areas are included in the South of Washington drainage area and existing conditions on the sites are included in the model in both pre- and post-project models as activities within the staging areas will be during the construction-phase only. The land use of the area surrounding the Project Site is medium residential (Exhibit 7). The VAPP site is currently classified as vacant/open area with a zero-percent impervious cover as are both of the possible staging areas.

The off-site drainage areas contribute to nodes within the Grand Canal using conduit connections in SWMM to represent hydrological routing, although hydrologic lagging or attenuation of runoff hydrographs is not included in the routing. The South of Washington and Site drainage areas combine with the upstream flows in the Grand Canal at the combination node.

The Direct Determination Runoff method is used to estimate runoff and generate hydrographs from the site within the SWMM model. Rainfall hyetographs are developed using the rainfall data downloaded from the Los Angeles County Department of Public Works Hydrology website as shown in Exhibits 13 through 15, and adjusted using the Design Storm Unit Hyetograph table from Appendix A in the Los Angeles County Department of Public Works Hydrology Manual (*Hydrology Manual*), dated January 2006 (Appendix B).

Table 1 in Appendix C lists hydrologic parameters associated with the site and the two Grand Canal drainage areas. Proposed conditions parameters are based on the concept site plans and Venice Auxiliary Pumping Plant Design report (*PDR*) provided by Arcadis (Appendix E) and the assumed LID size and configuration complies with the City of Los Angeles *LID Manual*. Existing conditions parameters are estimated from available data.

According to the City's *Geotechnical Report* dated December 14, 2015, artificial fill soils exist within the site as the result of previous construction and/or previous construction activities on the site. In general, the depth of fill is expected to be approximately three to four ft within the site. The fill materials generally consist of silty sand and sand with some construction debris. Given the depths of the proposed LID features, the bottom of the LID feature will likely be below the fill materials. Therefore, soils parameters are based on the assumed underlying native soils.

Alluvial sediments encountered in the borings contain primarily coarse-grained soils consisting of gravels, sands, and silty sands with interlayered fine grained soils consisting of silts and clays. Coarse-grained alluvial materials range widely in type and consistency from poorly graded sands and gravels to silty and clayey sands. Generally, the coarse alluvium soils are typically brown or light brown in color though they may be gray or olive with high fine contents in the case of silty or clayey sands. The coarse-grained materials are moist to wet, loose to very dense with varying amounts of silt, clay, gravel, and cobbles. The fine-grained materials are typically moist to wet.

Fine-grained alluvium consists of lean and fat (low to high plasticity) silts and clays of very soft to hard consistency. Generally, the fine-grained alluvial soils are brown, dark brown, dark gray or greenish gray in color. Seashells and seashell fragments were observed in many of the samples collected from the borings. These materials were observed to be interspersed anywhere within the matrix of the soil and as concentrated lenses and layers of several inches in thickness.

Since the alluvial sediments are indicated to vary in type and consistency from sands and gravels to silt, clay, gravel, and cobbles and the geotechnical report addresses "surface soils", native underlying soils at the VAPP site is assumed to be Yolo Clay Loam (Exhibit 8) with saturated hydraulic conductivity rates of approximately 0.040 inches/hour (from standard tables from the EPA *Sustain User's Manual*, as the geotechnical report did not include saturated hydraulic conductivity rates or other values needed for modeling).

The suction head and initial deficit parameters shown in Table 2 of Appendix C are estimated for a clay loam from standard soils texture tables and further details on data sources are included in this table. Soil types for the project area and watershed drainage areas were determined by using the soil types found in Exhibit 8 (Soil Map) and taking percentages of the three soil types present in the project area to estimate composite values. The three types of soil used from the map were Yolo Loam as loam, Chino Silt Loam as silt loam, and Yolo Clay Loam as clay loam. Green & Ampt parameters for these soils types were also estimated from standard *Sustain* tables.

Design Storm Results

The two-year, ten-year, and 100-year, 24-hour design storm events are modeled to assess runoff during an event similar to the water quality event, an event representative of storm drain sizing, and an extreme flood control event. As shown in Table 1 of Appendix C, the two-year, 24-hour, ten-year, 24-hour and 100-year, 24-hour rainfall depths at the site are 2.02, 3.72 and 5.85 inches (in), respectively. Exhibits 13, 14, and 15 each detail the rainfall depths. As indicated above, the design storm rainfall data is derived from the Los Angeles County *Hydrology Manual* (Appendix B). The rainfall hyetographs are used by SWMM to compute the design storm runoff hydrographs from the site.

As shown in Table 5 of Appendix C, proposed conditions peak flows at the site with the Alternative 1 LID (lined bioretention with underdrain) features are 67-percent less than existing flows from the site for the two-year, 24-hour event and 64-percent and 29-percent less than existing for the ten-year, 24-hour and 100-year, 24-hour events, respectively. Specifically, the existing two-year peak flow is 0.06 cubic feet per second (cfs) and the proposed two-year peak flow is 0.02 cfs, the ten-year existing peak flow is 0.14 cfs and the proposed peak flow is 0.05 cfs, and the 100-year existing peak flow is 0.24 cfs and the proposed peak flow is 0.17 cfs.

Also shown in Table 5 of Appendix C, proposed conditions peak flows in the Grand Canal with the Alternative 1 LID features are essentially zero-percent change from existing flows for the two-year, ten-year, 24-hour, and 100-year 24-hour events. Specifically, the existing two-year peak flow is 72.9 cfs and the proposed two-year peak flow is 72.8 cfs, the ten-year existing peak flow is 165.7 cfs and the proposed peak flow is 165.6 cfs, and the 100-year existing and proposed peak flows are 263.8 cfs.

The Alternative 2 (planter box and lined bioretention) proposed conditions peak flows from the site are also 67-percent less than existing flows from the site for the two-year, 24-hour event, seven-percent less for the ten-year, 24-hour event, and no change from the existing to proposed 100-year, 24-hour event. Specifically, the existing two-year peak flow is 0.06 cfs and the proposed 2-year peak flow is 0.02 cfs, the ten-year existing peak flow is 0.14 cfs and the proposed peak flow is 0.13 cfs, and both the 100-year existing and proposed peak flows are 0.24 cfs.

Similar to Alternative 1, the Alternative 2 proposed conditions peak flows in the Grand Canal essentially do not change or are slightly less from existing to proposed for the two-year, ten-year, and 100-year, 24-hour events. Specifically, the existing two-year peak flow is 72.9 cfs and the proposed 2-year peak flow is 72.8 cfs, the ten-year existing peak flow is 165.7 cfs and the proposed peak flow is also 165.7 cfs, and the 100-year existing and proposed peak flows are both 263.8 cfs.

Figures 2A through 4A depict runoff hydrographs from the site for the 2-year, 24-hour, 10-year, 24-hour and 100-year, 24-hour design storm events, respectively. Initial discharges are due to the assumed growing media saturation of 30-percent for the design storm events. Figures 2B through 4B depict runoff hydrographs from the Grand Canal system for the 2-year, 24-hour, 10-year, 24-hour and 100-year, 24-hour design storm events, respectively. The hydrograph in the Grand Canal is adjacent to the VAPP site where the flows from all three drainage areas combine at the Node “GrandCanal” and includes pre- and post-project discharges from the VAPP site.

As described, the proposed LID conditions peak flows and runoff volumes are illustrated by the maximum value of the runoff hydrographs and the area under the hydrograph curves, respectively. Additionally, the shapes of the proposed LID conditions runoff hydrographs generally match the shapes of the undeveloped conditions runoff hydrographs for the larger design storm events. Note that final modeling of underdrain sizes and retention times may result in additional hydrograph lagging.

Figures 5 through 7 illustrate storage depths within the following layers of the LID feature alternatives at the site:

- 18-inch surface storage layer of lined bioretention with underdrain
- 12-inch surface storage layer of planter box
- 30-inch drain rock layer of lined bioretention
- 30-inch drain rock layer of planter box

Due to impermeable bottoms, underdrains are included in the lined bioretention and planter box alternatives and are assumed to be located at the bottom of the drain rock layer.

Note that typical assumptions were made regarding the geometric configuration of the LID features (Table 4 of Appendix C). Additionally, assumptions on impervious area treated by the LID feature are listed in Table 3 of Appendix C. During the final design and modeling, it is possible that the hydrologic performance can be improved through changes in geometric configuration of the bioretention or incorporation of additional LID features.

The Alternative 1 proposed lined bioretention with underdrain functions as expected and fills to a depth of approximately 18 in in the 100-year, 24-hour event with a drain down time from the maximum storage level of approximately 15 hours. The maximum level during the ten-year, 24-hour event is just over 8 in with a corresponding drain down time of approximately 9 hours. The maximum level during the two-year, 24-hour event is approximately 2 in with a corresponding drain down time of approximately 3 ½ hours.

The water surface in the drain rock layer reaches a maximum of approximately 9 in in the 2-year event, 25.5 in in the 10-year event, and about 29 in in the 100-year design storm events. While the drain down time is much longer than for the surface storage, this is due to the required underdrain in the City's *LID Manual* criteria, which provides additional water quality and hydrologic benefits. Any vector control requirements should be addressed during the final design; however, this storage is located underground as opposed to above ground.

Similarly, the Alternative 2 proposed lined bioretention with underdrain also functions as expected and fills to a depth of 18 in in the 100-year, 24-hour event with a drain down time from the maximum storage level of approximately 15 hours. The maximum level during the ten-year, 24-hour event is also 18 in with a corresponding drain down time of just over 16 ½ hours. The maximum level during the two-year, 24-hour event is 5.5 in with a corresponding drain down time of nearly 7 hours.

The Alternative 2 proposed planter box feature also functions as expected and fills to a depth of approximately 12 in in the 100-year, 24-hour event and drains down from the maximum storage level in approximately 10 hours. The maximum level during the ten-year, 24-hour event is also 12 in with a corresponding drain down time of just over 11 hours. The maximum level during the two-year, 24-hour event is approximately 6 in with a corresponding drain down time of almost 8 hours. The water surface in the drain rock layer reaches a maximum of approximately 20 in in the 2-year event, approximately 27 in in the 10-year, and approximately 28 in in the 100-year design storm events.

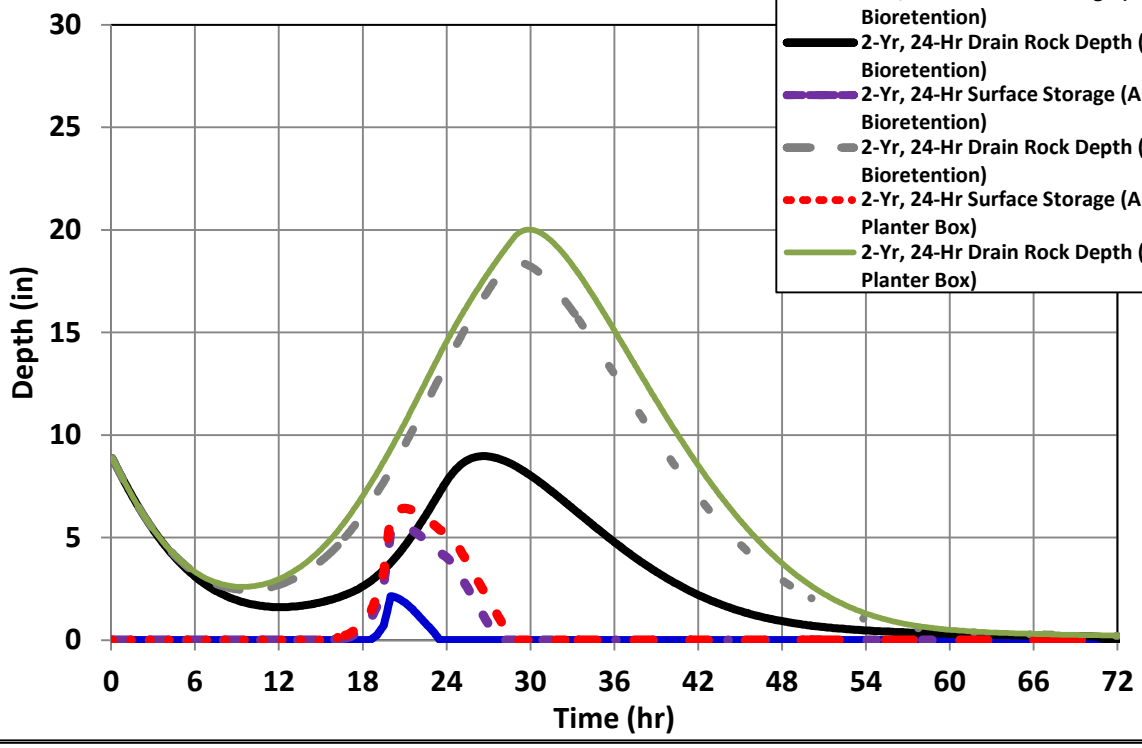

Figure 6: 10-Year Hydrographs from Biofiltration Features

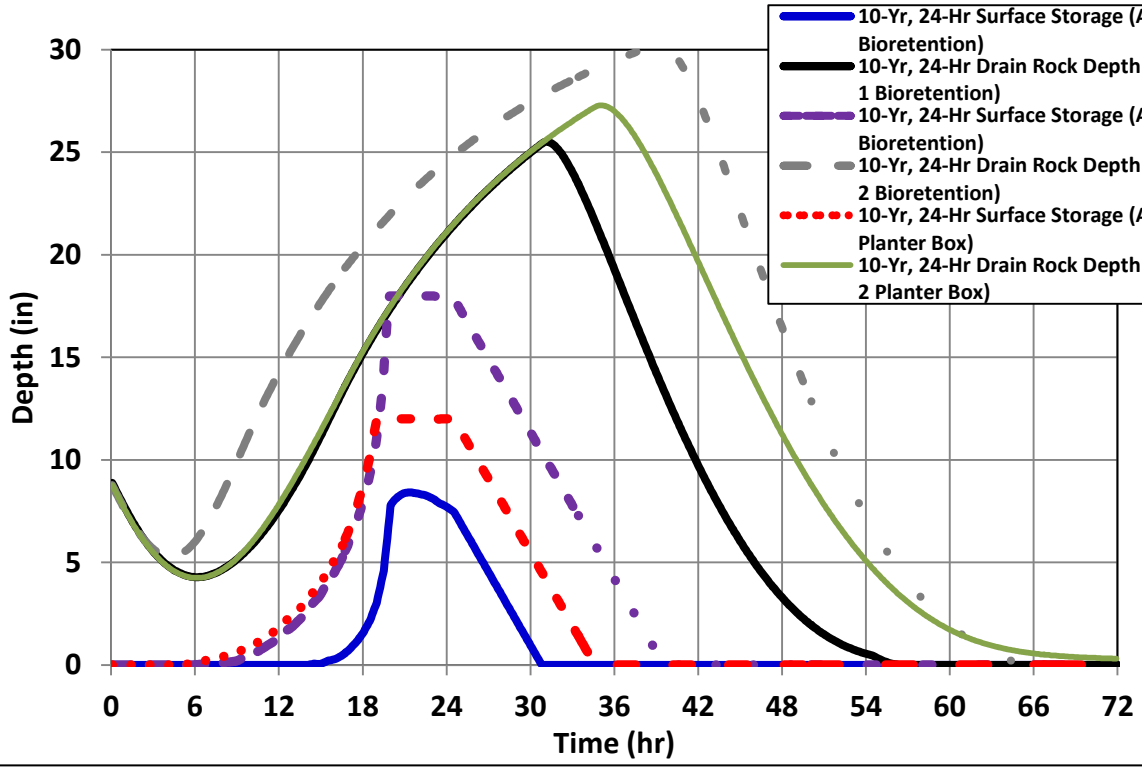

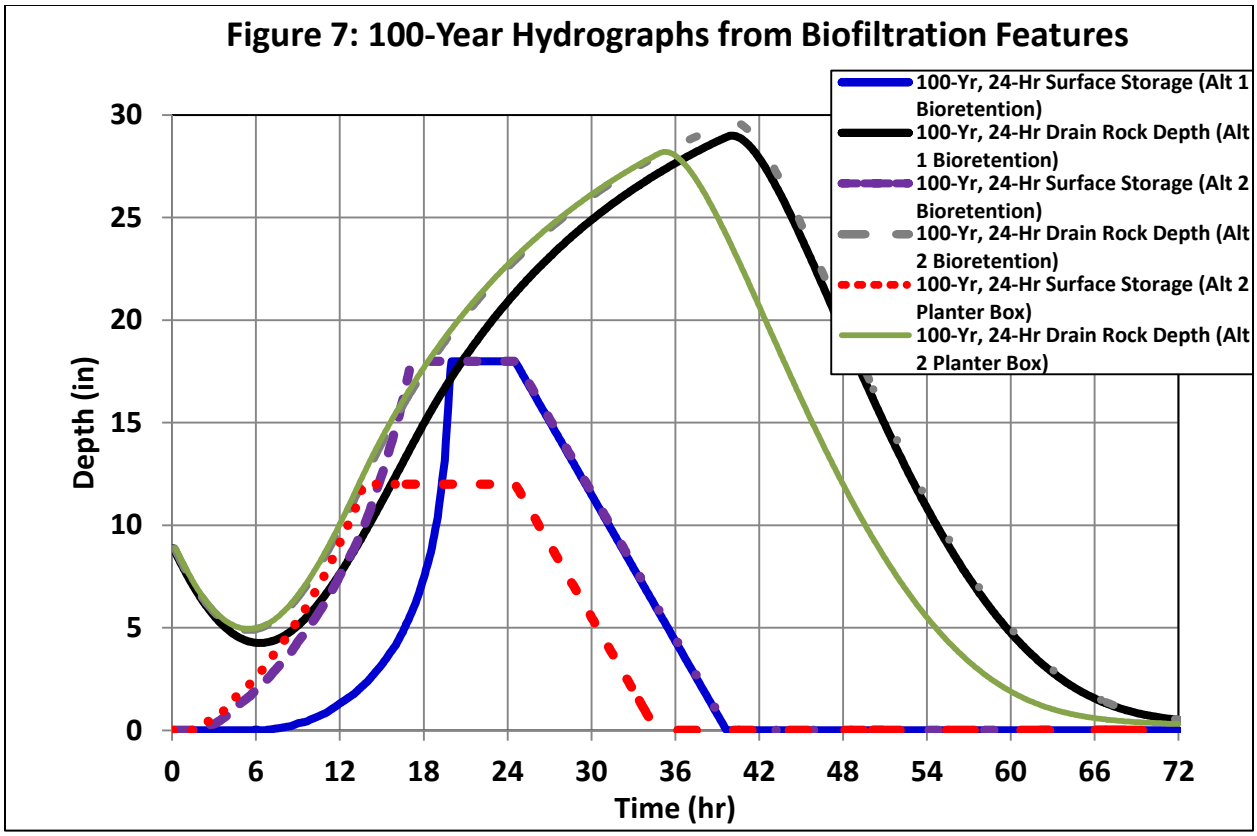

Continuous Simulation Results

A continuous simulation modeling analysis was performed based on 1970 – 2005 rainfall data obtained from the U.S. EPA's National Stormwater Calculator for the Santa Monica Pier gauge, which is located in closest proximity to the site. Average monthly evaporation data is also used from this gauge. While hourly data is used in the continuous simulation modeling analysis, daily events are summarized in this figure. Figure 8 illustrates historical daily rainfall totals during the period of record from 1970 – 2005 recorded at the Santa Monica Pier gauge. Days without rain are not shown on this graph.

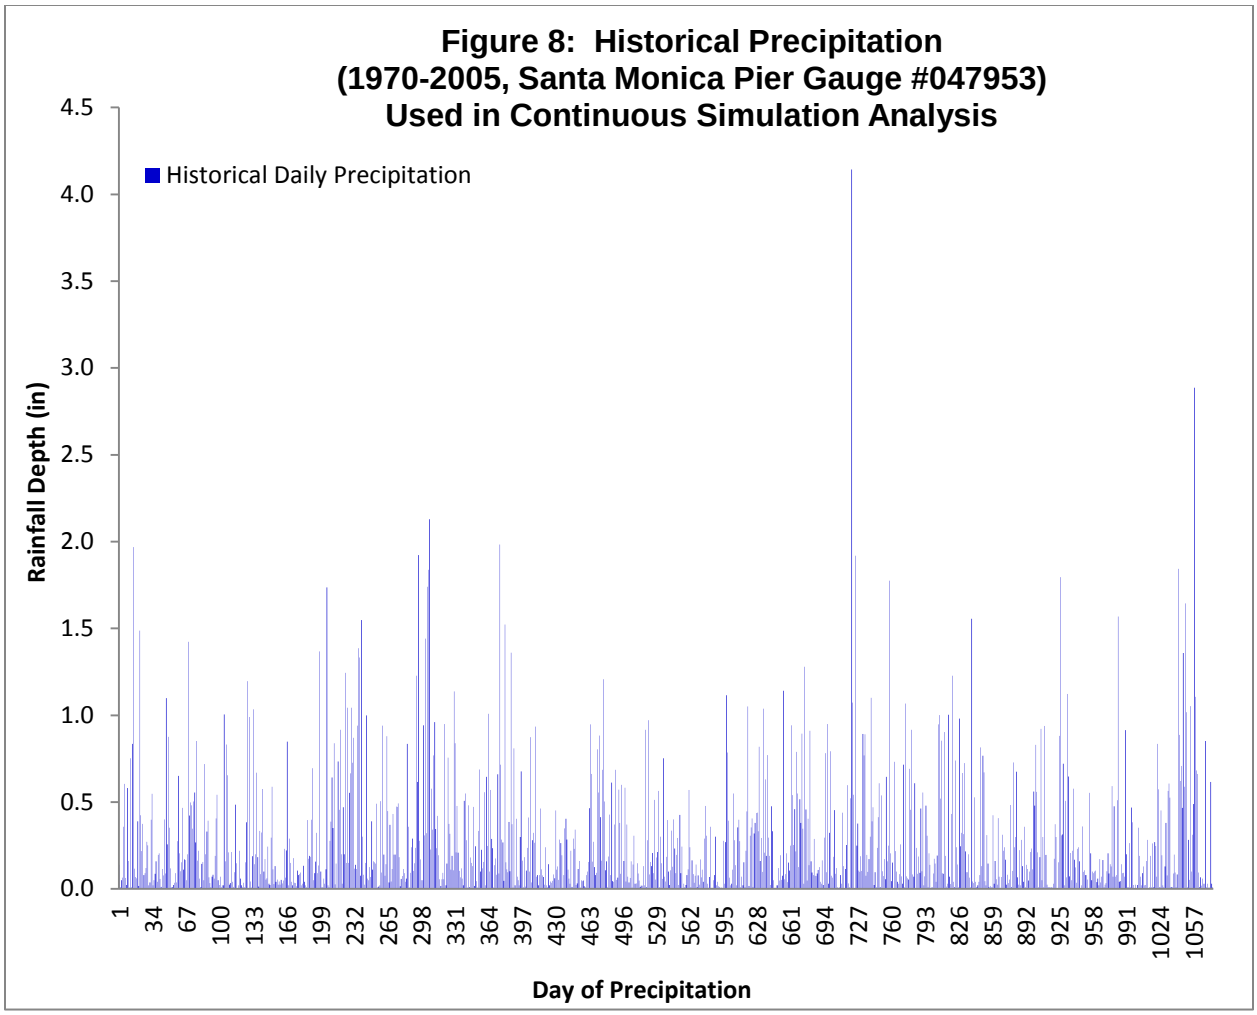

Table 6 in Appendix C includes water balance results for the continuous simulation analysis and summarizes infiltration, runoff, evapotranspiration, and precipitation. Annual maximum peak discharges from the site and in the Grand Canal are depicted in Figures 9A and 9B, respectively. For the entire period of analysis, maximum annual discharges from the VAPP site are less than or equal to existing discharges from the site. In all years, maximum annual discharges from the Grand Canal are equal to or less than existing discharges during the period of record between 1970 and 2005. Note that the actual results may change somewhat during final design and modeling depending on the final extent and configuration of LID features and impervious cover within the site.

Figure 9A: Maximum Annual Peak Discharge from Continuous Simulation Analysis at Site

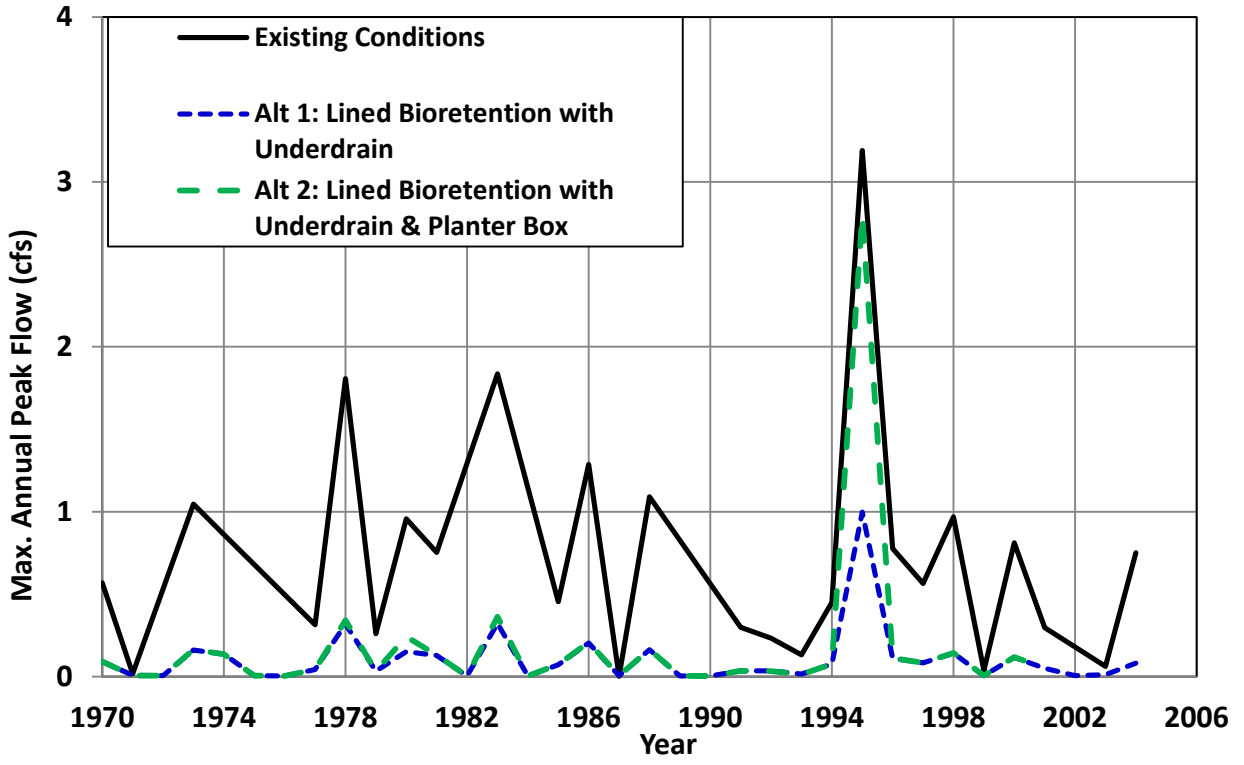

Figure 9B: Maximum Annual Peak Discharge from Continuous Simulation Analysis at Grand Canal

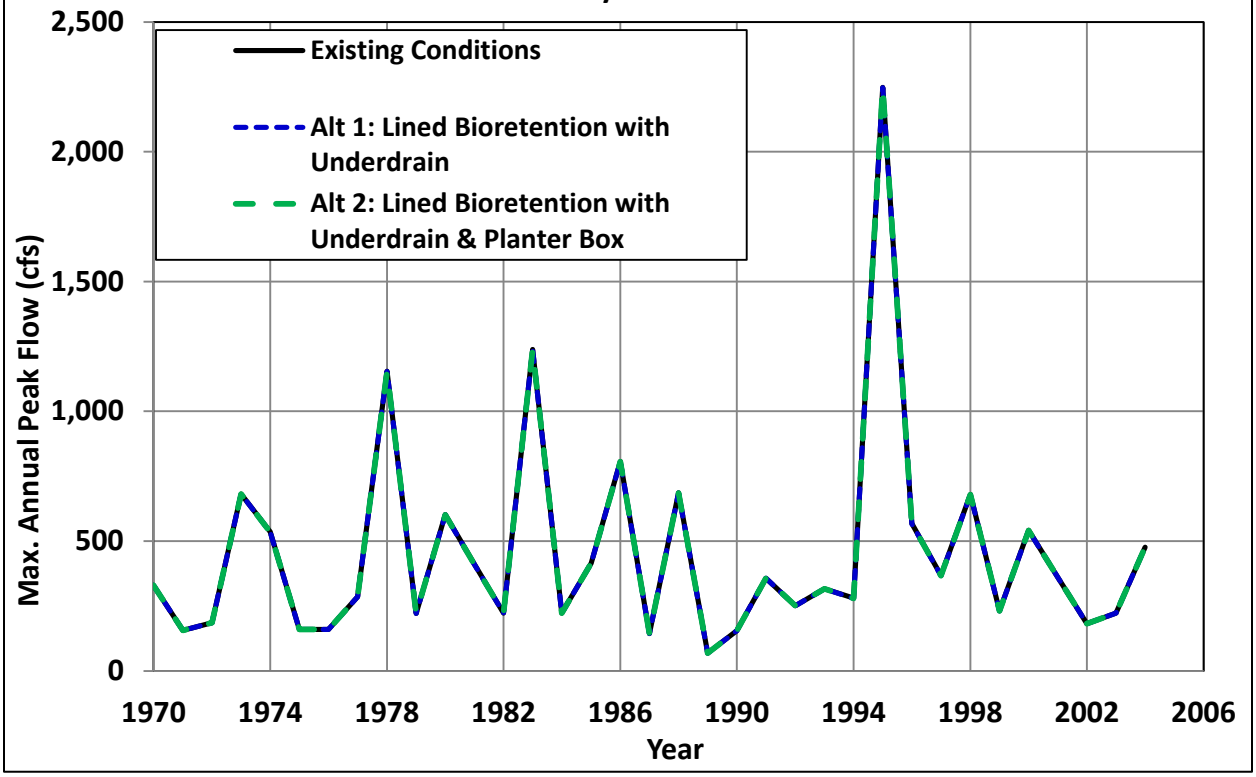
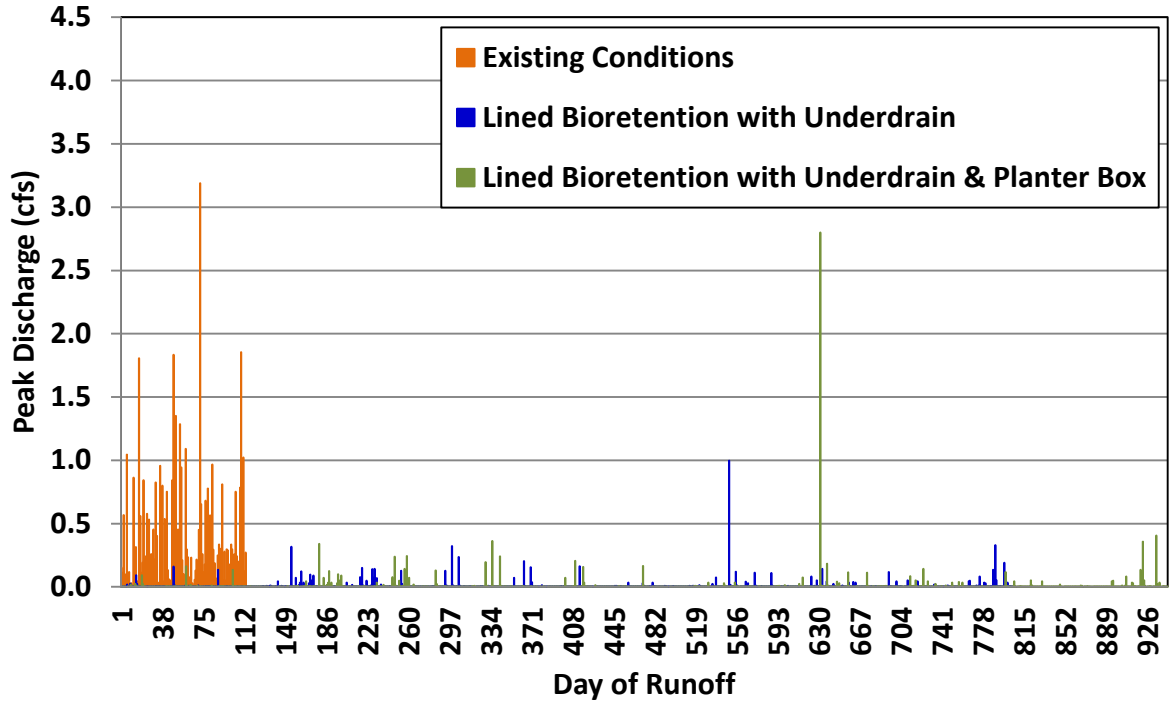


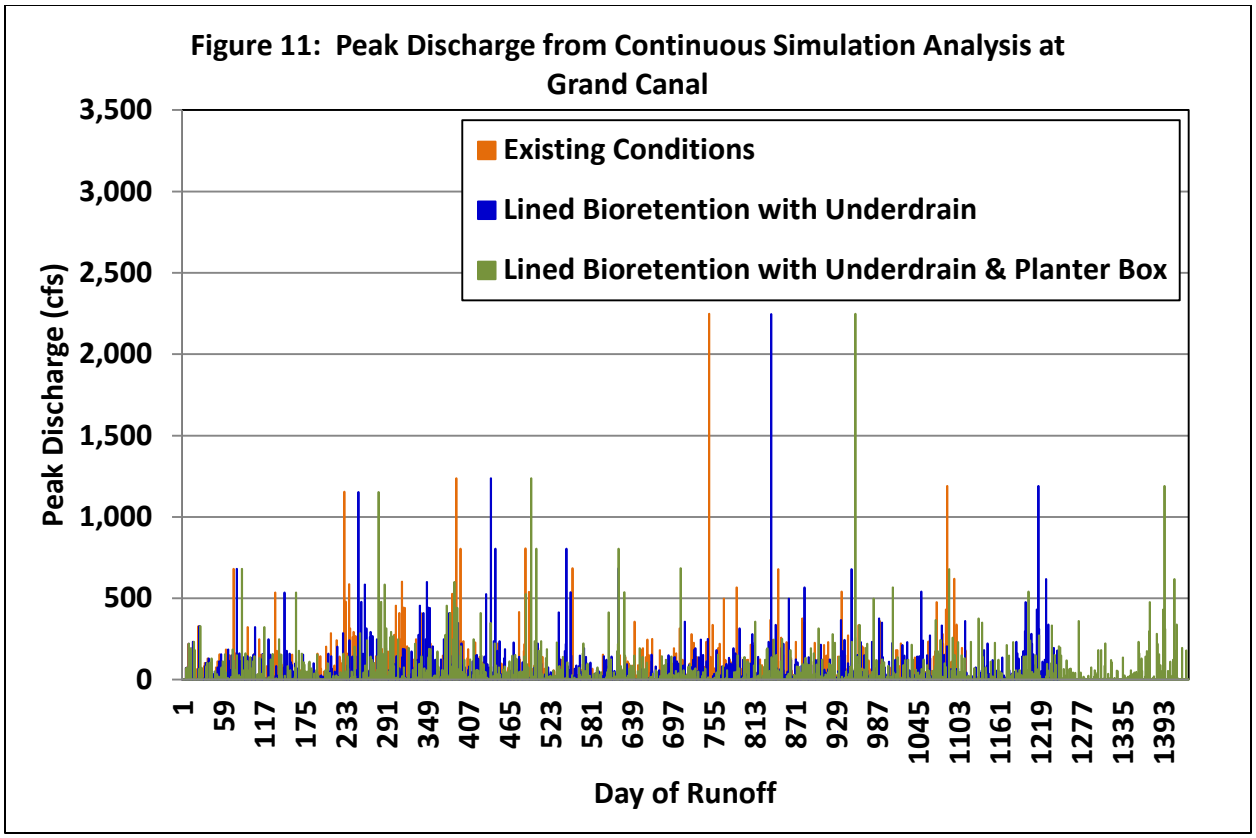
While a full hydromodification hydrology and hydraulics (HEC-RAS) frequency analysis is beyond the scope of this study, peak discharge impacts in the two-, ten-, and 100-year events are evaluated in the design storm section and continuous simulation modeling results are evaluated for maximum annual peak discharges and exceedance frequency curves. Additionally, the final design is required to comply with hydromodification hydrology and hydraulics (HEC-RAS) analyses for multiple design storm events (two-, five-, ten-, 25-, and 50-year) as specified in the City's *LID Handbook*.

Table 6 in Appendix C includes water balance results for the continuous simulation analysis and summarizes infiltration, runoff, evapotranspiration, and precipitation. During the simulated time-period, 300.74 in of rain occurred. Proposed Alternatives 1 LID conditions runoff at the site is reduced by 69-percent as compared to existing conditions and Alternative 2 conditions is reduced by 12-percent. There is essentially no change or less runoff for both Alternatives within the Grand Canal.

Figures 10 and 11 graphically illustrates runoff in existing and proposed conditions at the site. Note that the day of runoff (x-axis) is for each event and that the days do not correlate for each event. While, there are additional days of runoff from the proposed alternatives, this is due to the delayed discharge from the various layers of the LID features. The general pattern is that proposed LID peak discharges are less than existing peak discharges for both Alternatives 1 and 2.

Figure 10: Peak Discharge from Continuous Simulation Analysis at Site





Discharge exceedance frequency curves and flow duration graphs are provided in Figures 12 and 13. As illustrated in the discharge exceedance frequency curves, both proposed Alternatives 1 and 2 LID conditions flows from the site are equal or less than existing conditions for the range of events contained within the historical 1970 – 2005 rainfall data from the Santa Monica Pier gauge. For the flow duration curves, the proposed LID conditions flow durations appear to exceed existing conditions due to the slow, trickling release of runoff from the site.

WATER QUALITY ANALYSIS

Development of the VAPP site is anticipated to change the pollutant loading from the site into the Grand Canal and mitigation is needed to maintain pollutant loads from the site and within the Grand Canal at or below existing conditions. As described above, LID features are planned to mitigate hydrologic and water quality impacts from the site. This section includes discussions on pollutant removal performance of LID, water quality methodology, and water quality modeling results.

Pollutant Removal Performance of LID

The most significant water quality benefit of LID is removal of stormwater runoff from the storm drain system or receiving waters. The first flush of stormwater runoff during a rainfall event typically contains higher concentrations of pollutants than later rainfall. By directing this runoff through LID features and providing retention, infiltration into the various layers of the LID feature and/or the native soils below the LID, and evapotranspiration, the pollutants do not reach the receiving body of water.

Other pollutant removal processes achieved through LID include physical, chemical, and biological processes. Physical processes include filtering of sediment and pollutants, such as metals absorbed to the sediment. Degradation of fecal coliform bacteria also occurs by drying out and exposure to ultraviolet (UV) light from sun exposure. Biological processes include bioremediation and biodegradation. For example, hydrocarbons may be broken down by soil microorganisms.

Phytoremediation, or pollutant removal by plants, includes pollutant uptake into and bioaccumulation within the plants, release of some pollutants from plants into the atmosphere, and breakdown of pollutants at the soil-plant root interface. For the latter process, mycorrhizal fungi play an important role by attaching to the roots and extending microfilaments into the soil, which significantly increases the functional surface area of plant roots. Because native, or indigenous, plants have evolved to the unique microclimate of an area and typically have deeper roots and greater levels of micorrhizal fungi, incorporating these elements into LID may represent an increased opportunity for carbon sequestration in mitigating climate change.

The water quality benefits of LID are well documented with regards to TSS, fecal coliform bacteria, metals, hydrocarbons, and other pollutants. LID is also effective at removing nutrients (N and P) provided that background levels in the native soil and growing media are not excessive. Nitrate (NO_3) removal through LID requires specific design modifications to create anaerobic conditions and an energy source (Carbon) required for denitrification.

While the actual pollutant removal performance of GI features varies with pollutant loading, contributing drainage area, magnitude of rainfall event, antecedent moisture conditions, and specific design, typical pollutant removal rates are listed in Table 8 below. Table 7 in Appendix C includes event mean concentration (EMC) values for modeled pollutants for pre-project and post-project land use at the VAPP site. The specific pollutant removal rates for the various LID alternatives at the VAPP site used in the SWMM modeling are in Table 8 in Appendix C.

Additionally, nutrient removal rates may vary substantially due to potential for leaching from growing media and/or underlying soil as well as specific anaerobic conditions required for denitrification required to remove nitrate (NO_3).

See Appendix C for all tables of hydrology modeling data and results, including EMC values for the North of Washington and South of Washington drainage areas. As indicated previously, the two staging areas are included in the South of Washington drainage area and the land use is classified as vacant for both pre-project and post-project conditions.

TABLE 8: TYPICAL POLLUTANT REMOVAL RATES[1] FOR LID FEATURES

LID Features	Pollutant Percent Removal				
	TSS	Nitrogen	Phosphorus	Bacteria	Heavy Metals
Detention Basin (dry)[4]	30-65	13-45	15-45	<30	15-45
Retention Basin[4]	50-80	30-65	30-65	<30	50-80
Constructed Wetlands[4]	50-80	<30	15-45	<30	50-80
Infiltration Basin[4]	50-80	50-80	50-80	65-100	50-80
Infiltration Trench/Dry Wells[4]	50-80	50-80	15-45	65-100	50-80
Permeable Pavement[4]	65-100	65-100	30-65	65-100	65-100
Swales[4]	30-65	15-45	15-45	<30	15-45
Vegetated Filter Strips[4]	50-80	50-80	50-80	<30	30-65
Bioretention[3,5]	85[5]	32-99[3]	72[5]	70-92[3]	54-99[3]

[1]Ranges varying with particle size, pollutant loading and site conditions.

[2]Bioretention rates anticipated to be applicable for Rain Gardens as well.

[4]LID percent removal numbers were obtained from the U.S. EPA *Handbook Urban Runoff and Pollution Prevention Planning.*
[5]National Pollutant Removal Database/Other Sources Summarized by *Cost and Pollutant Removal of Storm-water Treatment Practices by* Weiss, Gulliver, and Erickson in May/June, 2007 *ASCE Journal of Water Resources Planning and Management*,

Water Quality Modeling Methodology

Pollutants selected and modeled for this report were based on the EPA's 303(d) list of pollutants of concern, those pollutants requiring a TMDL, pre-project sampling performed by the City, and pollutants of concern that were measured in previous Ballona Lagoon and Los Angeles land studies. The most common of the pollutants were selected based upon a comparison of the concentration rates and appearance in the land use changes that would occur post-construction when the project area changed from vacant area land use to light industrial land use. The following pollutants were modeled in the EPA SWMM model of the VAPP site and the Grand Canal watershed:

- total suspended solids (TSS);
- chemical oxygen demand (COD);
- total copper;
- total lead;
- total zinc;
- fecal coliform.

While selenium was listed as a pollutant of concern, it was assumed that it would be similar to other metals modeled in this report as data was not readily available on removal rates.

Table 9 below lists the Event Mean Concentration (EMC) and Table 10 lists the pollutant percent removal values for each pollutant modeled included in the water quality analysis. Both the two-year design storm event and the 36-year continuous simulation modeling runs were used for the water quality analysis. While representative, the two-year event is larger than the "water quality" event, it was used as a representative event and may overestimate pollutant loading that would occur in the "water quality" event. The two-year rainfall event is 2.02 in, the ten-year event is 3.72 in, and the 100-year rainfall event is 5.85 in the project area at the VAPP site. Table 1 in Appendix C shows the rainfall depths in the other two drainage areas contributing to the site and the Grand Canal.

TABLE 9: PRE-PROJECT AND POST-PROJECT EVENT MEAN CONCENTRATION VALUES[1] FOR VAPP SITE

Pollutant	Site	
	Pre-Project (Vacant)	Post-Project (Industrial)
	EMC	EMC
TSS (mg/L)	164.7	229.4
COD (mg/L)	40.0	65.0
Total Copper (µg/l)	9.1	31.0
Total Lead (µg/l)	30.0	114.0
Total Zinc (µg/l)	38.8	565.6
Fecal Coliform (MPN/100 L)	2,174.8	653,070.4

[1] Most Event Mean Concentration (EMC) values are from Table 7, *The Green Visions Plan for 21st Century Southern California*, 2006 (Appendix W). COD and Lead are from the EPA *Guide to Urban Stormwater Pollutant Concentrations*, 2006.

TABLE 10: POLLUTANT REMOVAL BY VARIOUS BIOFILTRATION PRACTICES

Pollutant	% Removal		
	Lined Bioretention[8]	Planter Box[8]	Vegetated Swale[9]
Total Suspended Solids (TSS)[1]	85	85	52[5]
Chemical Oxygen Demand (COD)[2]	40	40	40
Total Copper[3,4]	66	66	26
Total Lead[3,5]	63	63	13
Total Zinc[3,5]	68	68	38
Fecal Coliform[6]	81	81	30[7]

Notes
[1] Total Suspended Solids (TSS) removal rates based on National Pollutant Removal Database/Other Sources Summarized by Cost and Pollutant Removal of Storm-water Treatment Practices by Weiss, Gulliver, and Erikson in May/June, 2007 ASCE Journal of Water Resources Planning and Management
[2] Removal rates for Dissolved Oxygen (DO) and Biological Oxygen Demand (BOD) were not readily available. Chemical Oxygen Demand (COD) is the representative pollutant for modeling purposes. COD removal based on average organics removal of 40% or greater as documented in *Stormwater Management* Volume 3/Issue 1, February/March, 2015 article entitled *Soil Media Protects Salmon from Toxic Runoffs.* Vegetated swale assumed to bioretention due to required two feet of growing media.

[3] While Selenium is listed as a 303(d) pollutant of concern, it is not modeled as data is not readily available. Selenium removal by bioretention is expected to be similar to Total Copper, Total Lead, and Total Zinc.
[4] Total copper has an assumed removal rate, based on average removal rates for Total Lead and Total Zinc.
[5] Total Lead and Total Zinc removal rates for all features and TSS removal rates for vegetated swale based on *The Green Vision s Plan for the 21st Century Southern California* (Appendix W) prepared by the University of Southern California, dated April 2006.
[6] Fecal Coliform removal rates based on average from selected field and laboratory studies summarized in *Bioretention Technology: Overview of Current Practice and Future Needs* by Davis, Hunt, Traver, and Clar in March 2009, Journal of Engineering.
[7] Fecal Coliform removal rates for vegetated swales were obtained from the U.S. EPA *Handbook Urban Runoff and Pollution Prevention Planning.*
[8] Lined bioretention and planter box assumed to have similar removal rates to bioretention in the literature.
[9] Removal rates may be underestimated for vegetated swales due to required two feet of growing media.

Water Quality Modeling Results

Table 9 in Appendix C shows the pollutant effluent concentrations from the site with the two alternatives compared to the concentrations associated with existing conditions. For Alternative 1 (lined bioretention with underdrain), TSS increases are 0.3 lbs higher in the two-year event and 5.8 lbs less in the continuous simulation. However, COD is 1.0 lbs higher in the two-year event, but 0.4 lbs less annually. Copper, Lead, and Zinc are essentially zero in both existing conditions and proposed conditions for the two-year event and annually. Fecal Coliform has a 2.6 lbs increase in proposed conditions for the two-year event, but has no change annually.

Table 10 in Appendix C compares the pollutant effluent concentrations between existing conditions and the two Alternatives within the Grand Canal adjacent to the VAPP site. For Alternative 1 in the Grand Canal, the TSS is also increased in the two-year by 0.3 lbs and reduced 5.8 lbs annually, and COD has an increase of 1.0 lbs in the two-year event, but annually has a 0.4 lbs reduction. Copper, Lead, Zinc and Fecal Coliform do not change in the two-year event or annually.

The results for Alternative 2 are generally the same or just slightly less than Alternative 1. For Alternative 2 (planter box and bioretention), TSS increases are 0.1 lbs higher in the two-year event and also 5.8 lbs less in the continuous simulation. COD is 0.8 lbs higher in the two-year event, but 0.4 lbs less annually, similar to Alternative 1. Copper, Lead, and Zinc are zero lbs in both existing conditions and proposed conditions for the two-year event and annual continuous simulation. Fecal Coliform increases by 2.5 lbs in proposed conditions for the two-year event, but has no change annually.

In the Grand Canal, the Alternative 2 results for the two-year event indicate that TSS increases by 0.1 lbs and COD has an increase of 0.8 lbs. Annually, TSS decreases 5.8 lbs and COD

decreases 0.4 lbs, similar to Alternative 1. However, like Alternative 1, there is no change for the other pollutants during the two-year event or annual continuous simulation.

While annual pollutant loads are not increased from the VAPP site or in the Grand Canal for the modeled, we recommend that a vegetated filter strip be used as pre-treatment BMP to further reduce the TSS, COD and fecal coliform concentrations from the site in the two-year event and any remaining pollutants discharging to the Grand Canal. In Alternative 1, all impervious cover on the site should be disconnected and drain through the vegetated filter strip by overland flow. For Alternative 2, all portions of the site not draining to the planter box should be disconnected and drain through the vegetated filter strip by overland flow. Additionally, if Alternative 2 is selected the planter box underdrain should drain into the lined bioretention if site grading permits. Use of this pre-treatment BMP will also further reduce peak discharges from the site in smaller design storm events as well as concentrate removal of sediment and other maintenance activities outside of the primary BMP. Alternatively, a manufactured BMP could be used for pre-treatment.

HYDRAULIC ANALYSIS

This section discusses the proposed cofferdam and diversion structure within the Grand Canal, and the hydraulic analysis of the proposed cofferdam during construction-phase of the project.

Proposed Cofferdam and Diversion Structure

Construction of a temporary coffer dam during the construction of the VAPP facility is necessary to ensure dry bedding conditions for the underground structure foundations, per the *PDR* by Arcadis (Appendix E). Additionally, a diversion structure must be installed in the Grand Canal to maintain the existing operation of the VPP while the VAPP is under construction. A shaped invert from the diversion structure will direct flow to either the VPP or the VAPP.

Based on the PDR by Arcadis, the preliminary cofferdam proposed for the VAPP project will be constructed of soldier piles and sheeting and located in the Grand Canal adjacent to the site during the construction phase of the project. The cofferdam will be removed once construction is completed, but the diversion structure will remain in place and be utilized post-construction. According to the PDR by Arcadis, the dimensions of the cofferdam are 95 ft in length by 23 ft wide, whereas the width of the Grand Canal in the vicinity ranges from approximately 65 to 70 ft.

The required diversion structure will be 17 ft by 17 ft and located adjacent to the cofferdam and top of the structure will be at or below the existing bottom of the Grand Canal. It will be constructed of concrete with a City approved plastic liner. The diversion access tunnel structure is 66 in and located at the northern edge of the site and is connected to the cofferdam structure around the existing influent sewer (see *PDR* plans in Appendix E).

The design of the cofferdam is proposed to be flush to the bottom of the Grand Canal. However, there is a bottom seal added to keep the Cell 1 of the cofferdam water-tight and to resist buoyancy forces from groundwater. The seal also serves as a working platform for the workers to

construct the underground structures. The material of this seal is not discussed in the proposal, schematics, or PDR.

Scour may occur along a cofferdam depending on tidal currents, river currents, or wave-induced currents. A practical method of preventing scour is to deposit a blanket of crushed rock or heavy gravel around the cofferdam either before or immediately after the cofferdam sheet piles are set. Another method is to lay a mattress of filter fabric, covering it with rock to secure it in place. Scour and erosion control will be required as part of the cofferdam construction. Additionally, the bottom of the Grand Canal should be restored to existing conditions upon completion of construction.

Hydraulic Model

A Hydrologic Engineering Center-River Analysis System (HEC-RAS) hydraulic analysis of the Grand Canal was performed in version 4.1.0 to simulate the effects of the cofferdam and diversion structure partial obstructions during the construction phase of the project (Exhibit 16). Post-project conditions are not modeled as the partial obstruction of the Grand Canal will occur only during construction-phase of this project. The HEC-RAS hydraulic model is widely used and was developed by the U.S. Army Corps of Engineers (USACE).

Topographic survey data of the Grand Canal was provided by Arcadis (Appendix H) for the vicinity of the VAPP site and Library of Congress Historical data (Appendix P) was used upstream of the VAPP site at cross-section 1959.76 and this data appears to be based on MSL elevations. The survey data used to develop the HEC-RAS hydraulic model is based on the North American Geodetic Vertical Datum (NGVD) 1929 datum, and appears to be consistent with the cross-section depiction of the Grand Canal from the Library of Congress. Cross-section locations are depicted in Exhibit 16 and the cross-sections and WSELs are shown in Appendix J.

The cofferdam and diversion structure are modeled as blocked obstructions within the affected cross-sections. The crossing and tide gates at Washington Blvd were not included in the hydraulic model as development of a detailed hydraulic model was beyond the scope of this study. As such, the differences in WSEL from these structures were assumed to be similar in existing conditions and proposed conditions (construction-phase) modeled. A Manning's Roughness Coefficient (n-value) of 0.04 was assumed for the channel and an n-value of 0.12 was used in the overbanks to represent developed areas.

Starting water surface elevation (WSEL) data was obtained from the *Grand Canal Hydrology Plan*at the Marina Del Rey tide gate location. This tidal elevation is assumed to approximate conditions at the confluence of the Grand Canal and Ballona Lagoon. The dry, wet, and extreme wet starting water surface elevations were used as the downstream boundary conditions in various model scenarios.

The Dry Mode tides ranges shown in Table 1 of Appendix G are from mid-April to mid-October during the dry season when the Marina water level exceeds 2.25 ft Mean Sea Level (MSL). Wet Mode is from mid-October to mid-April (rainy season) and the water level exceeds 0.0 ft MSL. During both of these conditions, the water levels exceed the Ballona Lagoon water level and the

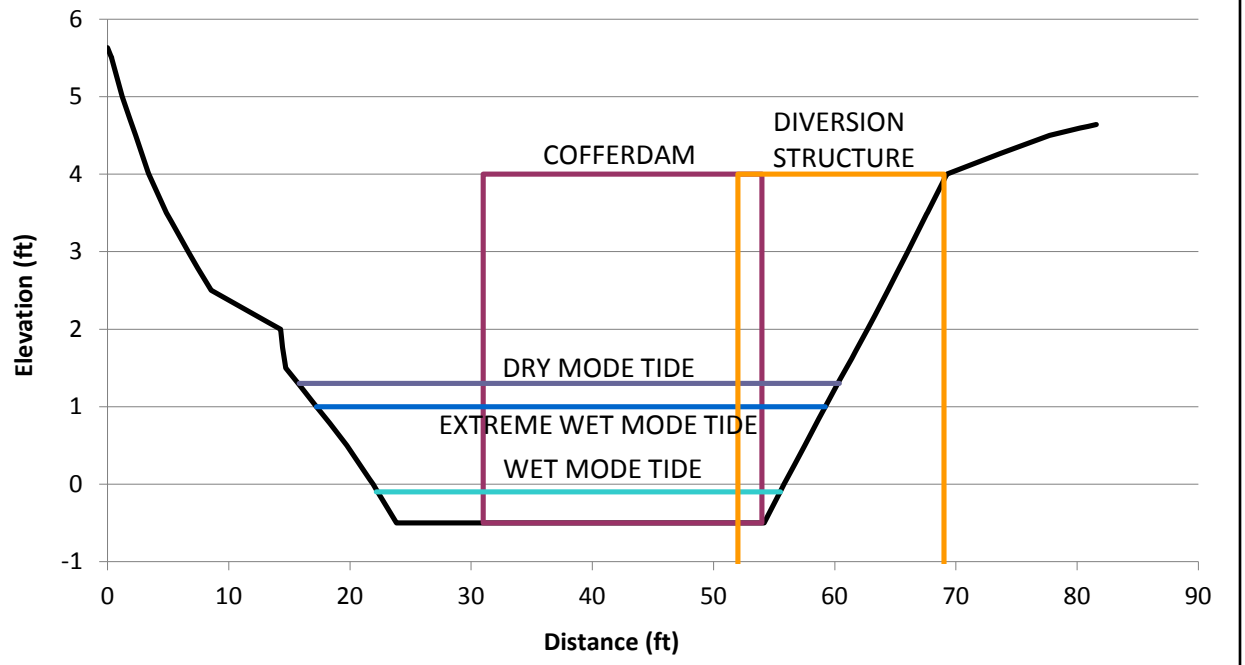
gates are closed until the Marina water level drops below the Lagoon water level. The Wet Mode, Extreme Flood event refers to operations during the rainy season when significant rainfall events are predicted. During this condition, the maximum water level predicted for the Wet Mode, Extreme Flood event operations are lower than the maximum water level during Dry Mode operations, which explains why the Dry Mode maximum WSELs computed in HEC-RAS are higher than the Wet Mode and Wet Mode, Extreme Flood scenarios.

The Wet Mode, Extreme Flood Event model from the *Grand Canal Hydrology Plan* modeled the Wet Mode as a 50-year, 96-hour event as opposed to the 100-year, 24-hour event evaluated in this study. The other events (Dry Mode and Wet Mode) were based on tidal influence only and did not include simulation of rainfall events. As detailed hydraulic model development was beyond the scope of this study and due to similarities in rainfall depth between the 100-year, 24-hour and 50-year, 96-hour events the Wet Mode event was assumed to provide an adequate basis for comparison. The Wet Mode rainfall frequency is weighted 13% of the year and Dry Mode inundation represents the remaining 87% of the year, according to the *Grand Canal Hydrology Plan*. According to NOAA Atlas 14, Volume 6, Version 2, the 50-year, 96-hour precipitation depth is approximately 10 in at the Santa Monica Pier station (Appendix V).

Figure 14 is an illustration of the Grand Canal cross-section adjacent to the site with the cofferdam and diversion structure temporary obstructions and tide elevations from the *Grand Canal Hydrology Plan*. The existing conditions model and proposed conditions model with the blocked obstruction were run with the following different starting WSELs (downstream boundary conditions) to estimate potential hydraulic impacts during construction phase by checking whether the proposed 100-year, 24-hour WSELs overtop the banks of the Grand Canal:

1. Dry Mode starting water surface elevation of 2.1 ft MSL (NGVD 1929)
2. Wet Mode, Extreme flood starting water surface elevation at 1.8 ft MSL (NGVD 1929)
3. Wet Mode starting water surface at 0.7 ft MSL (NGVD 1929).

FIGURE 14: Grand Canal XS Elevation Model



The design storm flow in the Grand Canal of 263.8 cfs was derived from the 100-year, 24-hour SWMM design storm model results and is consistent for existing and proposed conditions as no significant changes in runoff from the project are expected during construction. This design storm peak discharge is used in the existing and proposed Dry Mode, Wet Mode, and Extreme Wet Mode models. Based on our understanding of the operation of the tide gates, it is unlikely that the tide gates would be operated in the Dry Mode during a 100-year, 24-hour design storm event. To represent an extreme event, the 100-year 24-hour design storm event was analyzed with the starting WSEL from the Dry Mode. Additional simulations using the Dry Mode starting WSEL and essentially zero flow, or 0.01 cfs, were also modeled for the existing and proposed conditions comparisons and the results are shown in Table 11 below.

The following scenarios were modeled in HEC-RAS:

1. Existing Conditions – Dry Mode, Design Storm Flows
2. Proposed Conditions – Dry Mode, Design Storm Flows
3. Existing Conditions – Dry Mode, Zero Flows
4. Proposed Conditions – Dry Mode, Zero Flows
5. Existing Conditions – Wet Mode, Design Storm Flows
6. Proposed Conditions – Wet Mode, Design Storm Flows
7. Existing Conditions – Extreme Wet Mode, Design Storm Flows
8. Proposed Conditions – Extreme Wet Mode, Design Storm Flows

As shown in Table 11 below, there are increases in the WSELs with a maximum of 1.31 ft due to the proposed Project using Dry Mode starting WSELs and the design storm flows and no change in WSELs using the Dry Mode WSELs and zero flows. There is a maximum increase of 1.33 ft due to the proposed Project using the Extreme Wet Mode and Wet Mode WSELs and design storm flows. Table 12 reports the freeboard results from the Wet Mode models, which have the least amount of freeboard in proposed conditions. However, in all scenarios, the flow is contained within the channel banks as indicated by the freeboard available based on the left and right top of bank elevations. As such, there is no adverse impact to WSELs for rainfall events up to and including the 100-year, 24-hour event during the temporary construction of the cofferdam and diversion structure. Detailed hydraulic calculations and modeling results are attached as Appendix I. The temporary cofferdam is also not likely to cause significant impacts to operation of the tide gates at either end of the Grand Canal and Ballona Lagoon system.

Note: The site is located between cross-sections 127.09 and 241.75. The cofferdam is included in cross-sections 127.09 to 214.79 and the diversion structure is included in cross-section 214.79.

CONCLUSIONS

The VAPP project meets established hydrology, hydraulics, and water quality goals for the project:

- ✓ Meet City of Los Angeles LID and stormwater treatment criteria;
- ✓ Mitigate increased runoff from the VAPP site using LID and reduce proposed peak flows in the Grand Canal to existing conditions levels;
- ✓ Mitigate increased pollutant loads from the VAPP site using LID and reduce pollutant loads in the Grand Canal to existing conditions levels;
- ✓ No adverse impacts to 100-year WSELs or increased flooding risk associated with construction of the proposed cofferdam or diversion structure during construction.

Erosion control/energy dissipation is needed from the site discharge into the Grand Canal or it should outfall into the adjacent storm drain prior to discharging into the Grand Canal and also needs to meet the Venice Land Use requirements. Since there are small increases in the two-year, 24-hour design storm event TSS, COD, and fecal coliform, it is recommended that all impervious cover, including roof drains be disconnected and drain over a vegetated filter strip into the lined bioretention with the exception of areas draining to the planter box in Alternative 2. Alternatively, a manufactured product that removes TSS could be used. The pollutants can be further reduced by vegetated filter strips as indicated in the reference in Appendix T.

Detailed water budget modeling results from EPA SWMM are included in Appendix D.
To ensure the long-term functionality of the LID features and performance of the site, development of and compliance with an Operations & Maintenance (O&M) Plan is critical. Additionally, proper construction sequencing is critical to avoid premature sedimentation of the facilities.

Development of the VAPP site represents a significant opportunity for sustainability and LID within a densely urbanized area and for implementation of Green Infrastructure and LID for the City of Los Angeles as well as to provide pumping capacity to successfully manage wet weather flows and avoid raw sewage discharges or overflows into the Grand Canal and the Ballona Lagoon. Thank-you for the opportunity to collaborate on this visionary project.

APPENDIX C
TABLES OF HYDROLOGY MODELING DATA AND RESULTS

TABLE 1: SUMMARY OF HYDROLOGIC PARAMETERS FOR SITE

Hydrologic Parameters																	
Drainage Area	Area (ac)	24-hr Rainfall Data (in.)			Impervious Cover (%)		Overland Flow Length (ft)		Width (A/L) (ft)		Slope		Depression Storage (in)		Manning's n-value Impervious	Manning's n-value Pervious	
		2-yr	10-yr	100-yr	Exist	Prop	Exist	Prop	Exist	Prop	Exist	Prop	Impervious	Pervious		Exist	Prop
Site	0.18	2.02	3.72	5.85	0.0	75.0	95	95	83	83	2.48%	2.48%	0.06	0.25	0.012	0.023	0.240
North of Washington	102.18	2.10	3.88	6.10	68.5	68.5	115	115	38,702	38,702	0.12%	0.12%	0.06	0.25	0.012	0.200	0.200
South of Washington	93.22	2.05	3.78	5.94	82.6	82.6	115	115	35,310	35,310	0.02%	0.02%	0.06	0.25	0.012	0.200	0.200

Notes:

1. Hydrologic modeling performed in EPA SWMM 5.1.
2. Site assumed to route to outlet in existing and proposed conditions with 0% disconnected impervious cover.
3. Evaporation data based on the EPA National Storwater Calculator, Gauge 047953 (Santa Monica Pier Station).
4. Existing Site's Manning's n-value for pervious assumed based on gravel ground cover.
5. Continuous simulation model based on 1970 - 2006 data from Gauge Santa Monica Pier Station ID 047953 obtained from the EPA National Stormwater Calculator.
6. 24-hour rainfall data and hyetograph obtained from LA County.

TABLE 2: GREEN & AMPT SOILS PARAMETERS

Site	Native Soil Green & Ampt Parameters			Growing Media Green & Ampt Parameters							
	Suction Head (in)	Conductivity (in/hr)	Initial Deficit	Media Depth (in)	Suction Head (in)	Conductivity (in/hr)	Initial Deficit	Field Capacity	Effective Porosity	Wilting Point	Conductivity Slope
Site	8.270	0.040	0.267	18	2.4	1.18	0.312	0.105	0.437	0.047	8.0
North of Washington	6.949	0.136	0.317	-	-	-	-	-	-	-	-
South of Washington	8.270	0.040	0.267	-	-	-	-	-	-	-	-

Notes:

1. Native soil based on underlying soil type data from Los Angeles County Department of Public Works. See Geotechnical Report for information on the site's surface soil types: Artificial Fill and Alluvial Course Grained Soil.
2. Yolo Loam assumed as loam, Chino Silt Loam as silt loam, and Yolo Clay Loam as clay loam textures. Yolo Clay Loam Soil Type values used for drainage area South of Washington, as it's the predominant soil group.
3. Saturated hydraulic conductivity and suction head for native soil based on sandy clay values from EPA *SUSTAIN User's Manual* .
4. Initial moisture deficit for Western U.S. assumed from www.water-research.net.
5. Suction head values assumed for growing media from EPA *SUSTAIN User's Manual* . The conductivity value was selected to simulate long-term saturated hydraulic conductivity in the event of loss of capacity over time.
6. Loamy sand classification assumed for growing media.
7. Conductivity slope assumed from standard tables in SWMM5.0.021 User's Manual based on sandy loam growing media.

TABLE 3: LID FEATURES AREAS AND CONTRIBUTING AREAS FOR SITE

LID Feature	Avg. LID Area (sq. ft.[1])	LID % of Site	Drainage Area (sq. ft.)	Initially Saturated %[2]	% Impervious Area Treated[3]	Outflow to Pervious
Alternative 1: Lined Bioretention with Underdrain	700	8.9%	7,845	0/30	100%	No
Alternative 2: Lined Bioretention with Underdrain	380	5.7%	6,649	0/30	85%	No
Alternative 2: Planter Box	62	5.2%	1,196	0/30	15%	No

Notes:

1. Average surface area of LID feature used in SWMM modeling with a 2' minimum bottom width. The BMP minimum surface area required is 277 sq. ft. for Alternative 1 Bioretention, 230 sq. ft. for Alternative 2 Bioretention, and 62 sq. ft. for Alternative 2 Planter Box, and based on the water quality requirements in the City of Los Angeles Development Best Management Practices Handbook, Low Impact Development Manual, June 2011. However, the Bioretention surface areas are increased to mitigate impacts.
2. The % initially saturated for the LID growing media is 0% for the continuous simulation and 30% for the design storm.
3. % impervious area treated is percent of entire impervious area in 0.18-acre project drainage area as the aggregated method of LID modeling is used due to the site size. The planter box is treating the building roof area.

TABLE 4: LID CONFIGURATIONS FOR SITE

LID Feature	Avg. Surface Depth (in)	Surface Slope (%)	Top Width (ft)	Side Slope (H:V)	Surface Veg. Volume Fraction	Manning's n-value	Depth Soil Media (in)	Initial Media Saturation (%)	Storage/Drain Rock (in)	Void Ratio	Underdrain?	Drain Coefficent
Lined Bioretention with Underdrain	18.0	0.00%	---	---	0	0.24	36	30	30	0.5	Yes-0" above gravel bottom layer	0.2
Planter Box	12.0	0.00%	---	---	0	0.24	36	30	30	0.5	Yes-0" above gravel bottom layer	0.2

Notes:

1. Green & Ampt hydraulic parameters for growing media (amended soil) based on sandy loam with a hydraulic conductivity of 1.18 in/hr (see Table 2 for details).
2. For the lined bioretention and planter box alternatives, the saturated hydraulic conductivity of 0.00 in/hr assumed for underlying (native) soil (see Table 2 for details).
3. Initial media saturation used for design storm events only and not continuous simulation model.
4. Bioretention modeled with 0% slope due to SWMM model requirements.

TABLE 5: SITE DESIGN STORM EVENTS RESULTS

Note: Alternative 1 includes Lined Bioretention with underdrain and Alternative 2 includes a combination of Lined Bioretention with underdrain and Planter Box.

TABLE 6: SITE
CONTINUOUS SIMULATION WATER BALANCE OUTPUT

System Results	Analysis Period Results						
	Exist.	Alt. 1	Alt. 1 vs Exist.	Alt. 1 vs Exist. (%)	Alt. 2	Alt. 2 vs Exist.	Alt. 2 vs Exist. (%)
Precipitation (in)	300.74	300.74	0.00	0%	300.74	0.00	0%
Surface Runoff (in)	37.21	184.50	147.29	396%	192.38	155.17	417%
Infiltration (in)	262.93	60.13	-202.80	-77%	62.30	-200.63	-76%
Evaporation (in)	13.05	84.03	70.98	544%	75.14	62.09	476%
Maximum Peak Flow (cfs)	3.19	1.00	-2.19	-69%	2.80	-0.39	-12%
Maximum Peak Flow in Grand Canal (cfs)	2248.5	2246.5	-2.0	0%	2248.2	-0.3	0%

Notes:

1. Water balance output is for full continuous simulation run.
2. Initial saturation of 0% (wilting point) used for growing media at start of continuous simulation run.
3. Alternative 1 includes Lined Bioretention with underdrain and Alternative 2 includes a combination of Lined Bioretention with underdrain and Planter Box.

TABLE 7: PRE-PROJECT AND POST-PROJECT EVENT MEAN CONCENTRATION VALUES1 FOR VAPP SITE

	Site		North of Washington & South of Washington							
	Pre-Vacant	Post-Industrial	Pre & Post- High Density Residential	Pre & Post-Industrial	Pre & Post-Vacant	Pre & Post-Commercial	Pre & Post-Multi-Family Residential	Pre & Post-Transportation	Pre & Post-Education	Pre & Post-Multi-Mixed Use
Pollutant	EMC	EMC	EMC	EMC	EMC	EMC	EMC	EMC	EMC	EMC
TSS (mg/L)	164.7	229.4	104.7	229.0	164.7	67.4	46.4	75.4	103.0	69.1
COD (mg/L)	40.0	65.0	73.0	65.0	40.0	57.0	73.0	65.0	65.0	65.0
Total Copper (µg/l)	9.1	31.0	15.3	31.0	9.1	34.8	12.2	51.9	21.5	17.3
Total Lead (µg/l)	30.0	114.0	144.0	114.0	30.0	104.0	144.0	114.0	114.0	114.0
Total Zinc (µg/l)	38.8	565.6	80.4	5656.0	38.8	238.5	134.9	279.5	123.7	184.9
Fecal Coliform (MPN/L)	217,480.0	65,307,040.0	108,535,370.0	65,307,040.0	217,480.0	107,165,650.0	n/m	134,016,670.0	n/m	n/m

[1] Most Event Mean Concentration (EMC) values are from Table 7, The Green Visions Plan for 21st Century Southern California, 2006. COD and Lead are from the EPA Guide to Urban Stormwater Pollutant Concentrations, 2006.

[2] Modeled washoff exponent = 1.0 for all pollutants

TABLE 8: POLLUTANT REMOVAL BY VARIOUS BIOFILTRATION PRACTICES

Pollutant	% Removal		
	Bioinfiltration[8]	Planter Box/Lined Bioretention[8]	Vegetated Swale[9]
Total Suspended Solids (TSS)[1]	85	85	52[5]
Chemical Oxygen Demand (COD)[2]	40	40	40
Total Copper[3,4]	66	66	26
Total Lead[3,5]	63	63	13
Total Zinc[3,5]	68	68	38
Fecal Coliform[6]	81	81	30[7]

Notes

1. Total Suspended Solids (TSS) removal rates based on National Pollutant Removal Database/Other Sources Summarized by Cost and Pollutant Removal of Storm-water Treatment Practices by Weiss, Gulliver, and Erickson in May/June, 2007 ASCE Journal of Water Resources Planning and Management.
2. Removal rates for Dissolved Oxygen (DO) and Biological Oxygen Demand (BOD) were not readily available. Chemical Oxygen Demand (COD) is the representative pollutant for modeling purposes. COD removal based on average organics removal of 40% or greater as documented in *Stormwater Management* Volume 3/Issue 1, February/March, 2015 article entitled *Soil Media Protects Salmon from Runoff Toxics*. Vegetated swale assumed to match bioretention due torequired two feet of growing media.
3. While Selenium is listed as a 303(d) pollutant of concern, it is not modeled as data is not readily available. Selenium removal by bioretention is expected to be similar to Total Copper, Total Lead, and Total Zinc
4. Total Copper has an assumed removal rate, based on average removal rates for Total Lead and Total Zinc
5. Total Lead and Total Zinc removal rates for all features and TSS removal rates for vegetated swale based on *The Green Visions Plan for 21st Century Southern California* prepared by the University of Southern California, dated April, 2006.
6. Fecal Coliform removal rates based on average from selected field and laboratory studies summarized in *Bioretention Technology: Overview of Current Practice and Future Needs* by Davis, Hunt, Traver, and Clar in March, 2009 Journal of Environmental Engineering.
7. Fecal coliform removal rates for vegetated swales were obtained from the U.S. EPA *Handbook Urban Runoff and Pollution Prevention Planning*.
8. Bioinfiltration and planter box/lined bioretention assumed to have similar removal rates to bioretention in the literature
9. Removal rates may be underestimated for vegetated swales due to required two feet of growing media

1. Executive Summary

1.1 Introduction

The City of Los Angeles (City) currently owns and operates the Venice Pumping Plant (VPP) near the Ballona Lagoon and Venice Beach. The pumping plant is the City's largest pumping plant and is considered a critical facility to convey sewage from the tributary area.

Heavy storms during the 1994-1995 and 2004-2005 resulted in periods of heavy rainfall, infiltrated stormwater, and high sewage flows, which put the VPP within minutes of overflowing into the lagoon. One or more pumps at VPP are occasionally out of service for extended periods which would put the VPP at serious risk during peak wet weather flow conditions.

The main objectives of the Venice Auxiliary Pumping Plant (VAPP) Project are as follows:

- Provide a new pumping plant adjacent to the existing VPP that will house three pumps of similar capacity as the existing pumps at VPP.
- Provide a new electrical building with lavatory, control and server rooms, electrical/mechanical rooms, and a generator room.
- Provide a 24 KW Tier 4 Final Certified Emissions diesel generator.
- Provide site security for both VPP and VAPP.
- Provide VPP and VAPP control capabilities from both VPP and VAPP.

1.2 Related Projects

The following projects are related to the construction of the VAPP Project:

- Manifold Replacement Project
  - Existing manifold was replaced with a new 60-inch steel manifold with connections to the VPP, the existing 48-inch force main, and stub-outs for the VAPP and future 54-inch force main.
- Venice Dual Force Main Project
  - A new 54-inch force main will tie into the new manifold and will discharge at a junction box near the Hyperion Treatment Plant. The new force main will be provided to add capacity and redundancy to the existing 48-inch force main.
- Electrical Generator Upgrades Project
  - The existing generators at VPP, two 750-kW and one 1500-kW, will be replaced to meet Tier 4 Final Certified Emissions.
- Distributed Control Systems Replacement Project

- The City-wide Distributed Control Systems (DCS) replacement program known as LAWINS will be replacing the existing local controllers and aging remote monitoring system with a Honeywell-based DCS.

1.3 Pump Station Design

Current peak flows for VPP and VAPP are as follows (Development of a Conceptual Plan for an Auxiliary Pumping Facility Alternative for the Venice Pump Plant, Carollo, 2014):

- Ultimate Peak Wet Weather Flow: 87 MGD (Design based on 10-year storm event)
- Ultimate Peak Dry Weather Flow: 71 MGD
- Current Peak Wet Weather Flow: 55 MGD (January 6, 2009)
- Current Peak Dry Weather Flow: 36 MGD
- Minimum Low Dry Weather flow: 15 MGD (Design)

The main components of the pump station consists of the following:

- Diversion structure on the existing influent sewer
- Influent piping
- Concrete wet well
- Three submersible pumps
- Discharge piping valves and flow meters
- Sluice gate
- Generator
- Electrical Equipment
- Instrumentation and Controls

A complete hydraulic evaluation was performed. The evaluation was based on the following hydraulic scenarios:

Table 1.1 - Hydraulic Scenarios

Scenario	Pump Operating	FM Operating
A	1 pump / 2 pumps	48” FM only
B	2 pumps/3 pumps/4 pumps / 5 pumps	48” FM only
C	2 pumps/3 pumps/4 pumps / 5 pumps	54” FM only
D	2 pumps/3 pumps/4 pumps / 5 pumps	Both FMs
E	6 pumps/7 pumps/8 pumps	Both FMs

Based on the hydraulic evaluation the results were reviewed with multiple submersible pump manufacturers (Flygt, KSD, and ABS). Flygt’s model CP 3531/905 with a 500-HP is shown in the following two figures below. Refer to **Section 5** for pump curves for KSD and ABS.

Figure 1.1 - Dual Force Main Operating - 1 & 2 Pumps (Flygt)

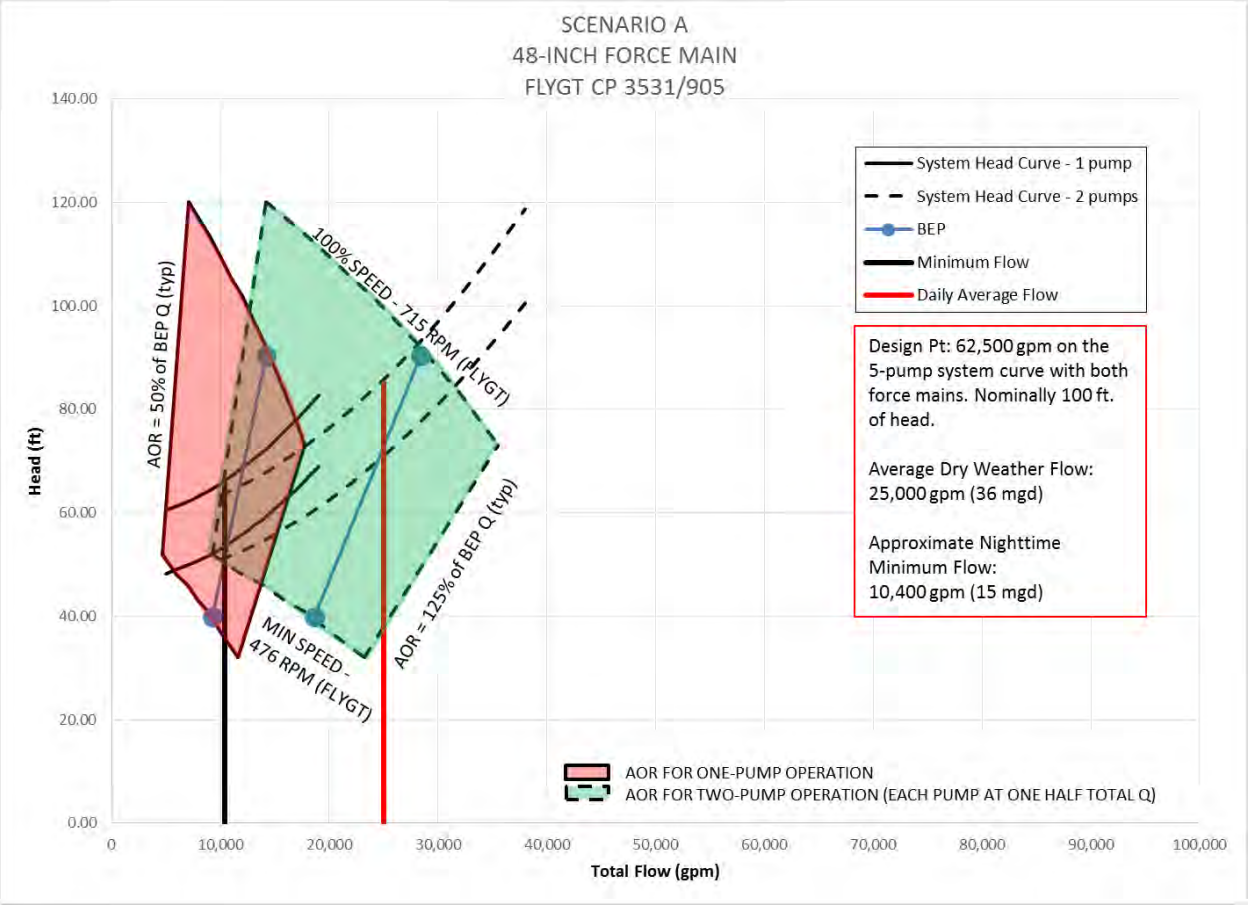

Figure 1.2 - Dual Force Main Operating - 4 & 5 Pumps (Flygt)

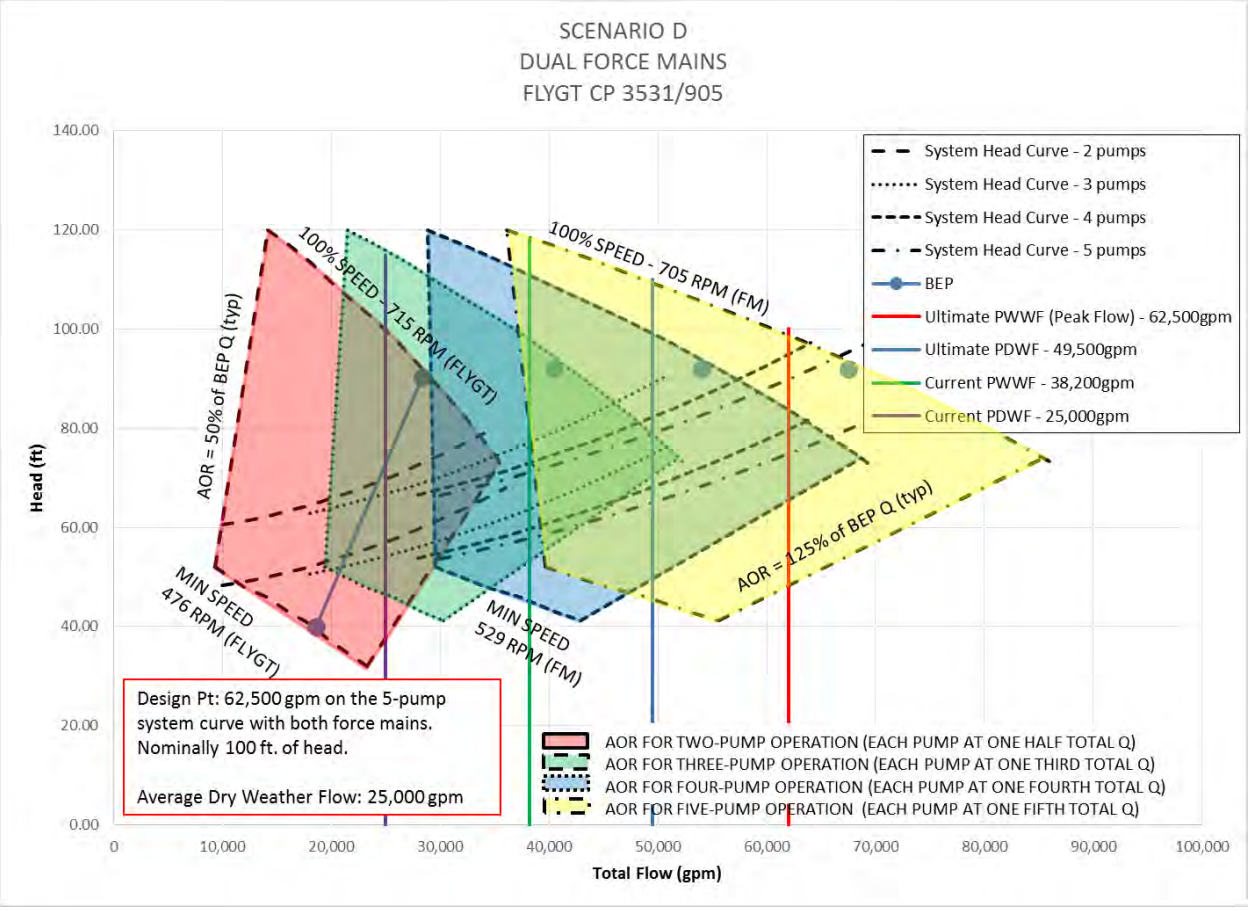

After reviewing pump curves from several manufacturers, we concluded Flygt pump was the best selection for this application. Its operating points are the closest to the best efficiency point lines while staying to the right of the BEP lines and provides the best system curve coverage. The following table summarizes the motor size and best hydraulic efficiency for each pump.

Table 1.2 - Motor Information

Manufacturer	Max Required Shaft Power by Pump	Motor Rating (input power)	Best Hydraulic Efficiency
ABS	405	449	82.5%
Flygt	410	500	84.2%
KSB	440	493.5	82.3%

1.4 Site/Civil Design

The VAPP will be located north of the existing VPP across Hurricane Street. The site for the VAPP is approximately 0.18 acres. Improvements include a two-story 50 foot by 25 foot area electrical building, a pump station with associated piping, electrical and security improvements. East of VAPP a small pocket park will be created.

Overhead power lines through the VAPP site will be routed south, along the western property line crossing Hurricane Street, and turning east along Hurricane Street in close proximity to VPP.

Potable water, sewer, electrical and communications will be needed for VAPP. It is anticipated that most connections will be made along Canal Court to avoid conflicts with the manifold and the pump stations.

1.5 Site Security

The VPP site is secured, but it does is not equipped with access monitoring or video surveillance. An access control and video surveillance system will be provided for VPP and VAPP to protect operators working between the two sites.

Features of the security design will include the following:

- Access control and monitoring
- Video surveillance
- Network features

Major equipment list includes:

- Fixed and pan/tilt/zoom video cameras
- Digital video recording equipment
- Computer workstation(s)

1.6 Building Design

The VAPP building will include electrical, mechanical, control, server, generator, and lavatory rooms. Perimeter walls will be reinforced concrete with cool roofing system above the second floor. Finishes include architectural stamped concrete, reveals and architectural impressions. Metal awnings will be provided above each exterior door. Materials will be selected to ensure that oxidation is kept to a minimum.

Interior features include furred walls with insulation and painted gypsum board finishes in occupied spaces, resilient flooring in occupied spaces, and either sealed concrete or sustainable flooring such as epoxy coating in other spaces. A clean agent system will be provided for fire protection.

1.7 Electrical Design

The electrical design required for the VAPP Project will include providing two new 480V services from the two existing 34.5KV primary circuits that serve VPP. A new 34.5KV switching cabinet, two new 34.5KV-480V transformers and two new secondary 480V pull sections will also be provided. Two circuit breakers at the existing VPP will be replaced with two 480V, 1600A power circuit breakers and connected to the VAPP 480V power switchgear. The electrical system will be provided with a 480V motor control center (MCC) to distribute 480V power to common loads.

A small diesel generator will provide backup power to VAPP critical loads in the event of loss of power from LADWP. The generator will provide 24KW of power at 120/240V for lighting, the SCADA system, security and access control system, and air conditioning for the VAPP control and server room.

Major electrical equipment for VAPP is as follows:

- 480VAC switchgear, in a main-tie-main arrangement
- 480VAC MCC for auxiliary equipment
- 500HP rated VFDs with reduced voltage soft start bypass motor controllers

1.8 Instrumentation and Control Design

The VAPP and VPP will operate as a single pump station with their respective wet wells hydraulically linked with similar elevations and even flow split. The VAPP will be monitored and controlled by a local programmable logic controller (PLC). A distributed control system (DCS) will collect information and provide operator interface. The VAPP will operate similar to the existing VPP. The VPP will be integrated into the VAPP network and DCS.

The design of the communications network will include electronic communications for all equipment at the VPP and the VAPP.

1.9 Project Delivery

An important requirement for this project is to install the diversion structure in the Grand Canal. It is important to maintain the existing operation of the VPP while construction for VAPP is implemented. Important below grade preliminary construction sequencing has been developed for this project and is included in this report.

Following City's approval of the Preliminary Design Report for this project, anticipated to be by December 2015, the design and construction of this Project is expected to proceed as follows:

- Detailed Design: December 2015 through September 2016.
- Approval to Construct: January 2018
- Notice-to-Proceed: February 2018
- Substantial Completion: December 2019
- Final Completion: February 2020

The Class C construction cost estimate for this project is **$16,011,000**. The cost opinion was developed using equipment vendor quotations (for major equipment), previous cost data, unit costs and RS Means cost estimating guides as necessary, and is based upon preliminary information defined for equipment selection and layout, piping requirements and routing, mechanical, electrical and instrumentation requirements.

2. Introduction

2.1 Project History and Background

The City of Los Angeles (City) currently owns and operates the Venice Pumping Plant (VPP) near the Ballona Lagoon and Venice Beach. The pumping plant is the City's largest pumping plant and is considered a critical facility to convey sewage from the tributary area.

Per the VPP Dual Force Main Environmental Impact Report (December 2007), heavy storms during 1994-1995 and 2004-2005 resulted in periods of heavy rainfall, infiltrated stormwater, and high sewage flows which put the VPP within minutes of overflowing into the Ballona Lagoon. Peak wet weather flow conditions were met because the City had all five of the VPP pumps running at full capacity. However, one or more pumps at the VPP are occasionally out of service for extended periods which would put the VPP at serious risk during peak wet weather flow conditions.

The City has contracted with ARCADIS for engineering services necessary to increase the pumping capacity and redundancy to allow maintenance to take place without compromising the City's ability to maintain pump station performance during peak wet weather flows.

2.2 Description of Existing Facilities

Flow enters the VPP via a single 66-inch reinforced concrete sewer pipe which discharges into two existing wet wells. Wet well No. 1 serves Pumps 1 through 4, and wet well No. 2 serves Pump No. 5.The VPP includes five (5), 400-hp dry pit centrifugal pumps. The design capacity of each pump is 18 million gallons per day (MGD) at 100 feet total dynamic head (TDH). The pumps are served by a new 60-inch manifold connecting a 48-inch force main and a future second 54-inch force main. Both force mains would be used to convey flows from VPP and VAPP to a diversion structure two miles to the southeast, near the intersection of Vista Del Mar and Gills Street, and ultimately to the Hyperion Treatment Plant (HTP).

2.3 Purpose

The purpose of this Preliminary Design Report (PDR) is to present the basis of design for the Venice Auxiliary Pumping Plant (VAPP), which includes a two-story electrical and control building, three (3) 18-MGD submersible pumps, a diversion structure, and a valve and metering vault.

3. Related Projects

3.1 Manifold Replacement Project

The VPP Discharge Manifold Replacement Project began construction in summer of 2012. The project consists of removing the existing manifold structure and installing a new 60-inch steel manifold with connections to the VPP, the existing 48-inch force main, and stub-outs at both ends for connection to the future 54-inch force main and the VAPP. Construction was completed in August 2015.

3.2 Venice Dual Force Main

The City is in the process of designing and constructing a 54-inch diameter force main in the same vicinity, known as the Venice Dual Force Main Project. The new pipeline alignment will cross Grand Canal from VPP northerly along Hurricane Street to Marquesas Way, then southerly along Via Marina crossing the Marina Del Rey and Ballona Creek Channels to the Coastal Interceptor Sewer (CIS) Diversion Structure on Vista Del Mar near Waterview Street. See **Figure 3.1** for the 54-inch force main route. The new force main will operate as a parallel system in conjunction with the existing 48-inch force main to meet the peak wet weather flow demands experienced at VPP, and to add operational flexibility and reliability. Construction on the Venice Dual Force Main project is expected to be completed in three years once all of the necessary permits have been obtained.

Figure 3.1 - 54-Inch Force Main Route

3.3 Electrical Generator Upgrades

The existing diesel-fueled standby engine-generators at VPP are aging and do not meet the anticipated future regulatory requirements of the Environmental Protection Agency (EPA) Tier 4 Final Certified Emissions Standards. Two new 750-kW Tier 4 rated generators and one new 1,500-kW upgrade for VPP are to be procured and installed through the Venice Dual Force Main Project. This project is currently in design.

3.4 Distributed Control Systems Replacement Project

The City-wide Distributed Control Systems (DCS) Replacement Program is an “in progress” effort known as LAWINS. The LAWINS program is the City-wide replacement of the existing local controllers and aging remote monitoring system with a Honeywell-based DCS. The new control room in the VAPP electrical building will serve as the new control center for DCS main servers and workstations, and as “base” for plant operators. As part of the LAWINS program, the existing process controls at the VPP will be converted to the Honeywell-based DCS system for local and remote control via the DCS workstations located at the VAPP control room.

4. Site Investigation Findings

4.1 Noise and Sound Analysis

ARCADIS conducted noise and sound monitoring at four sensitive locations at the project site. The Baseline Noise Measurement Memo showing the baseline noise levels surrounding the project site during non-construction hours is included in **Appendix A**.

ARCADIS will coordinate with the City and perform additional noise and sound analysis as needed.

4.2 Air Dispersion of Collection System/Wet Well Odors

The VPP is equipped with an exhaust fan that discharges vapors through an existing stack. Based on our preliminary evaluation, we are not anticipating major changes to the existing dispersion stack. However, field investigation of the ventilation fan shows that the flange connecting the fan to the dispersion stack is displaced and odors can exit through the gap at the joint. We recommend replacing the existing fan, with one of comparable capacity, and flange as part of the VAPP project.

Any odors in the Coastal Interceptor Sewer (CIS) piping will be confined to that piping system and be handled as they normally are at the VPP. When the VAPP is in operation, the head spaces of the wet wells are linked by the 66-in sewer, and the exhaust fan can service the entire system. No additional odor control measures are anticipated.

4.3 Surveying

Survey of the VAPP site was completed on April, 20th, 2015. Refer to Topographic Survey in **Appendix B**. Additional survey of Hurricane Street and VPP will be included in the final PDR.

4.4 Permitting Requirements

Permit requirements for the project will be coordinated with LADPW and the Environmental Management Group as needed. **Table 4.1** lists the anticipated permits for the VAPP Project.

Table 4.1 – Anticipated Permits

Agency	Permit
LA Planning Department	Zoning Change
LA Planning Department	CDP-1
California Coastal Commission	CDP-2
USACE	Section 10 or 404 (NW 2, 12, 33)
California Regional Water Quality Control Board	NPDES SWPPP
California Regional Water Quality Control Board	401C Certification
U.S. Fish & Wildlife	Notification
National Marine Fisheries Service	Consultation/Notification
California Department of Conservation, Division of Oil, Gas and Geothermal Resources	Construction Notification
California Department of Health Services	Title 22 Compliance, Section 64630 (via LA County Environmental Services Division
City Department Cultural Affairs	Design Review
California AQMD	Permit to Construct and Permit to Operate
City BOE “B”	Permit for Major Street Construction
City BOE “E or U”	Permit for Excavation in City Streets
City BOE “W”	Permit for Construction in a Watercourse
City Building & Safety	Plan Checks

5. Pump Station Design

5.1 Design Flows

The VPP and VAPP will have an ultimate peak flow capacity of 87 MGD which is based on the ultimate wet weather flows (10-year storm event). This flow was determined by the City's peak wet weather modeling results (Development of a Conceptual Plan for an Auxiliary Pumping Facility Alternative for the Venice Pumping Plant, Carollo, 2014). The current peak wet weather flow was provided by LADPW historical data for the VPP, dated January 06, 2009. The summary of the flows below are the basis of design for the VAPP.

- Ultimate Peak Wet Weather Flow: 87 MGD (Design)
- Ultimate Peak Dry Weather Flow: 71 MGD
- Current Peak Wet Weather Flow: 55 MGD (January 6, 2009)
- Current Peak Dry Weather Flow: 36 MGD
- Minimum Low Dry Weather Flow: 15 MGD (Design)

The VAPP will include three submersible pumps designed to operate in a wastewater environment. They will have the ability to pass 4-inch diameter solids. Further details on the pumps are included in the sections below.

5.2 Major Process Components

The VAPP major process components include the following:

- Diversion structure on the existing influent sewer
- Influent piping
- Concrete wet well
- Three submersible pumps
- Discharge piping valves and flow meters
- Sluice gate
- Electrical equipment
- Generator
- Instrumentation and Controls

The diversion structure will be constructed around the existing influent sewer. The diversion structure will be made of concrete with a City approved plastic liner, and a shaped invert to direct the flow to either the VPP or the VAPP. Access shall be provided via a manhole connecting the diversion structure to the wet well. Additionally, no permanent means to isolate flow to either VPP or VAPP will be provided within this diversion

structure. If isolation of the VPP is required, a temporary plug could be provided in a manhole downstream of the new diversion structure. The VAPP will have a slide gate at the wet well that will be used for isolation.

Influent piping will be provided from the new diversion structure to the new wet well. The pipe will be concrete cylinder pipe lined to protect from corrosion due to hydrogen sulfide. Concrete structures that are exposed to the sewage will also be lined.

The wet well will be a below-grade structure that will contain the wastewater prior to pumping. Access will be limited to this structure, and hatches will be provided for maintenance access. Refer to the drawings in **Appendix B** for additional information on the wet well structure.

The discharge valves and piping will be made of ductile iron. The interior will be lined to protect from wear and corrosion. Check valves will be provided on each discharge line downstream of the pumps. Flow meters will then be installed to confirm flow from each pump. Isolation valves will be provided on each line in order to isolate the pumps, check valves and flow meters for maintenance. All of the valves and flow meters will be located just below grade in a concrete vault. Access hatches will be provided to maintain the equipment.

5.3 Operations & Maintenance Requirements

The VAPP will have three pumps installed and available to operate all times. The operation of the VAPP will be similar to the VPP. The pumps will adjust speed in order to meet a wet well level set point. Three submersible pumps will be provided with variable frequency drives (VFD) that will adjust motor speed to vary discharge flows. Sufficient overlap of pump operating ranges will be provided so that each pump flow condition will allow for the most efficient pump operation.

The VPP and the VAPP will operate independently with separate controls, but because they are located close together and connected via the influent sewer, they will act as one large wet well. The set points for the pumps for each station need to be reviewed and adjustments made during start-up in order to achieve this objective. Ideally the pumps will operate to maintain a constant water surface level using the VFDs and a set of pump operational parameters (e.g. lead, lag 1, lag 2 etc.). The control system will also provide the ability to operate each pumping plant independently if one of the pumping plants needs to be taken out of service for maintenance.

The VAPP will have the ability to be isolated from the influent sewer by a slide gate located at the entrance to the wet well. VPP does not have the capabilities to be isolated, therefore, in order to isolate the VPP for wet well maintenance, a temporary plug will be required at the upstream manhole, otherwise VPP will remain operational at all times.

The VPP currently discharges into a single 48-inch force main. The City is in the process of designing and constructing a second 54-inch force main. Therefore, the VAPP will need to be able to pump through one or both force mains at varying flow conditions. The force main manifold is equipped with motorized valves that can direct flow to each force main. It is anticipated that the control system will open and close the force main isolation valves as required to maintain flows within a minimum and maximum velocity range. The ideal force main velocity range is between 3 feet per second (FPS) to 8 FPS; the low flow limit is to keep solids suspended, and the high flow limit is to prevent pipe scour. Based on this range, **Table 5.1** outlines the suggested force main operational range.

Table 5.1 - Force Main Operating Range

Force Main	Low Flow Limit (3 FPS)	High Flow Limit (8 FPS)
Existing 48-inch	16,900 GPM (24.4 MGD)	45,099 GPM (64.9 MGD)
New 54-inch	21,400 GPM (30.8 MGD)	57,078 GPM (82.2 MGD)

The City will have flexibility once the second force main is operational. Operating outside the ranges is permissible for limited periods of time. Based on a low flow of 10,400 GPM (15 MGD) it is recommended to operate only one force main. A second force main should be used as a back-up, or during wet-weather periods. The control system can be set up to do this operation automatically.

The maintenance requirements for the VAPP process equipment will mainly focus on the submersible pumps. It is recommended that each pump be pulled once per year for inspection. The design will allow for disconnection of the cables at the wet well. This will allow for cable removal without going all the way back to the VFDs in the electrical building.

5.4 Process Mechanical Considerations

It is important that all process mechanical material selection is suitable for sewage and saline environments. It is specifically important in raw wastewater facilities. The design will incorporate corrosion resistant coatings for concrete and piping where appropriate. 316 Stainless steel and approved plastic liners will be specified for components that are directly exposed to wastewater.

The design layout will also consider the need to operate and maintain the process equipment. The need for jib cranes, access hatches, hook points and maintenance space have all been reviewed and will be incorporated where appropriate.

The design of the wet well is based on the latest version of the Hydraulic Institute standards (HI 9.8). The approach length and pitch of the influent sewer are specifically designed to minimize air entrainment and turbulent flow conditions. When flow enters the wet well, there is a baffle structure that will direct the water to the pump intakes. For additional information on the wet well configuration, see the drawings in **Appendix B**.

5.5 Physical Model of Influent Sewer, Wet Well and Pump Intakes

Given the size and configuration of the VAPP, it is recommended that a physical hydraulic model be constructed in order to optimize the intake design. ARCADIS will utilize an independent laboratory to conduct a physical hydraulic model study of the VAPP to optimize the design. A separate report will be issued once the physical modeling is complete. The physical model will not be completed in time for its results to be incorporated in the final PDR; however, the physical model results will be incorporated in the detailed design.

5.5.1 Benefits of Physical Hydraulic Models

The pump manufacturer typically develops pump curves at the manufacturing facility. The head-flow curves, efficiencies, net positive suction head, and power requirements are usually determined by conducting a pump test with the actual prototype pump or a geometrically similar model. This pump test is conducted in a controlled environment with uniform approach flow to the pumps. Therefore, to ensure that the pump will perform as tested at the manufacturing facility; the prototype field installation must also have similarly uniform approach flow conditions.

Failure to provide these uniform approach flow hydraulics can result in pump performance that differs significantly from that predicted from the performance curves. The pump may not operate at its best efficiency point, flow or head may be less than expected, power requirements may vary, and if the approach flow conditions vary enough, significant damage could occur to the pump itself.

Pump sumps are often designed to adhere to the 2012 Hydraulic Institute Standards (HI 2012). A consortium of pump manufactures, engineers, and end users developed these standards. Failure to adhere to these standards can lead to a number of problems including air entrainment, vortex activity, skewed velocity distributions and turbulence at the pump impeller. Research has shown that these conditions can lead to fluctuating loading on pump impellers, vibration, cavitation, and decreased flow and efficiency (Sweeney and Rockwell 1982).

Physical models are used to evaluate the level of temporal velocity fluctuations, or turbulence, within the pump bell. Changes in pressure are directly related to changes in velocity. Therefore, velocity fluctuations, whether temporal, or as a result of skewed approach flow, can cause pressure fluctuations on the pump

impeller. These pressure fluctuations translate into a loading imbalance on the pump shaft, possibly causing vibration or pre-mature bearing wear.

Physical models are also used to evaluate the uniformity of the flow within the pump bell. Should more flow be traveling down one side of a pump bay than the other, such as that which occurs when there is flow separation at the bay entrance, the velocity may be higher on one side of the impeller or the other. This may cause pre-swirl of the flow entering the pump. Depending on the direction of the pre-swirl relative to the pump rotation, this may cause the pump to consume more or less power than anticipated, resulting in the pump operating at a point other than its best efficiency. The pre-swirl may also result in the flow hitting the impeller blade at an angle of attack other than what it was designed for. This can result in localized flow separation on the impeller. These separation zones can cause low-pressure regions, which result in localized areas of cavitation.

In addition to evaluating turbulence and flow uniformity, conducting the physical model may result in reducing the length of lateral required from the gravity collector to the wet well and minimizing the dimensions of the wet well, both of which could result in direct construction cost savings for VAPP.

5.6 Hydraulic Analysis

A complete hydraulic analysis was performed on the VPP and VAPP systems to verify the VAPP pump head and flow requirements. Refer to the preliminary design calculations in **Appendix C**. We referenced the following documents:

- Venice Pump Plant at 39th Avenue and Esplanade Drawings (1958)
- 48-Inch Force Main in 39th Avenue Drawings (1959)
- Venice Pumping Plant Reconstruction Drawings (1985)
- Venice Dual Force Main Drawings (2014)
- TOS S64: Development of a Conceptual Plan for an Auxiliary Pumping Facility Alternative for the Venice Pumping Plant Technical Memorandum (Carollo, 2014)

The VAPP wet well elevation was modeled at (-) 14.1 to (-) 6.1; the discharge elevation range modeled was 40.5 to 44.5. This results in a static head of 46.6 ft. to 58.6 ft. between the VAPP and discharge diversion structure. Friction losses for the two force mains were modeled and resulted in the system head curves included in the figures in **Section 5.7**.

In order for all eight pumps to operate properly the friction losses at VPP need to be similar to the losses at VPP. All of the in-plant losses between the stations were taken into account. Friction losses include losses from valves and fittings inside each of the pump stations up to and including the manifold. All pumps have

the same design points to prevent one station from over powering the other with high flow and higher head losses.

We anticipate the final wet well level set point to be approximately (-) 10.1 when operating both VPP and VAPP. This will allow the water level to fluctuate approximately 4-ft and provide sufficient flexibility for the two wet wells to operate as one and prevent pumps chasing set points. The control system will be designed to adjust the VFDs appropriately so speed changes are controlled and within limits of the equipment.

Multiple hydraulic scenarios were reviewed as listed in **Table 5.2**.

Table 5.2 - Hydraulic Scenarios

Scenario	Pump Operating	FM Operating
A	1 pump / 2 pumps	48” FM only
B	2 pumps/3 pumps/4 pumps / 5 pumps	48” FM only
C	2 pumps/3 pumps/4 pumps / 5 pumps	54” FM only
D	2 pumps/3 pumps/4 pumps / 5 pumps	Both FMs
E	6 pumps/7 pumps/8 pumps	Both FMs

It was determined that scenarios A and D were the most critical to the design selection, so they are included in the figures in **Section 5.7**. Scenario A was selected because it shows the current condition and would provide for the higher head condition on the pumps if the larger force main was unavailable. Scenario D has two force mains operational and the maximum flow required (design condition).

Pumping systems develop transient hydraulic conditions (surge waves) when pumps start and stop. These conditions can damage piping systems if pressure ratings are exceeded. Currently, there are no known problems with transient/surge conditions at the VPP. Since the maximum flow rate through a single force main is not increasing, and the maximum velocity is decreasing as a result of the additional force main, transient conditions should not occur. If the force mains are operated in a manner that results in higher velocities, then new transient issues could develop. Since this is not the intended operation mode, and there are no known transient issues, ARCADIS does not anticipate a transient analysis is required. We suggest that this approach be confirmed during the upcoming PDR review meeting.

As requested in the RFP, the design point for the new pumps at the VAPP shall be 12,500 GPM (18 MGD) at 100 TDH each.

5.7 Pump Sizing and Selection

Following the hydraulic analysis task, the results were reviewed with multiple submersible pump manufactures (Flygt, ABS, and KSB). In the following sections, the pump curves of the most optimal product from each manufacturer are overlaid on the system curves for Scenarios A and D. The minimum and average daily flows are shown on the first figure for each pump manufacturer, and the peak flow is shown on the second. The shaded regions shown in the figures correspond to the Allowable Operating Region (AOR) for each pump operating scenario. The graphs illustrates the overlapping of flow coverage under various flow and head conditions that the pumps will experience. The circle points with the line connecting them represents the Best Efficiency Point (BEP) line for the particular pump. When selecting a pump, it is important to operate as close to this line as possible and determine the ultimate operation of the pumps based on this value. Refer to **Appendix D** for equipment cut sheets.

5.7.1 ITT Flygt

Flygt's model CP 3531/905 with a 500-HP is shown in the two figures below. The minimum and daily averages are shown on the first figure and demonstrate the operational range of this pump selection.

Figure 5.1 - Dual Force Main Operating - 1 & 2 Pumps (Flygt)

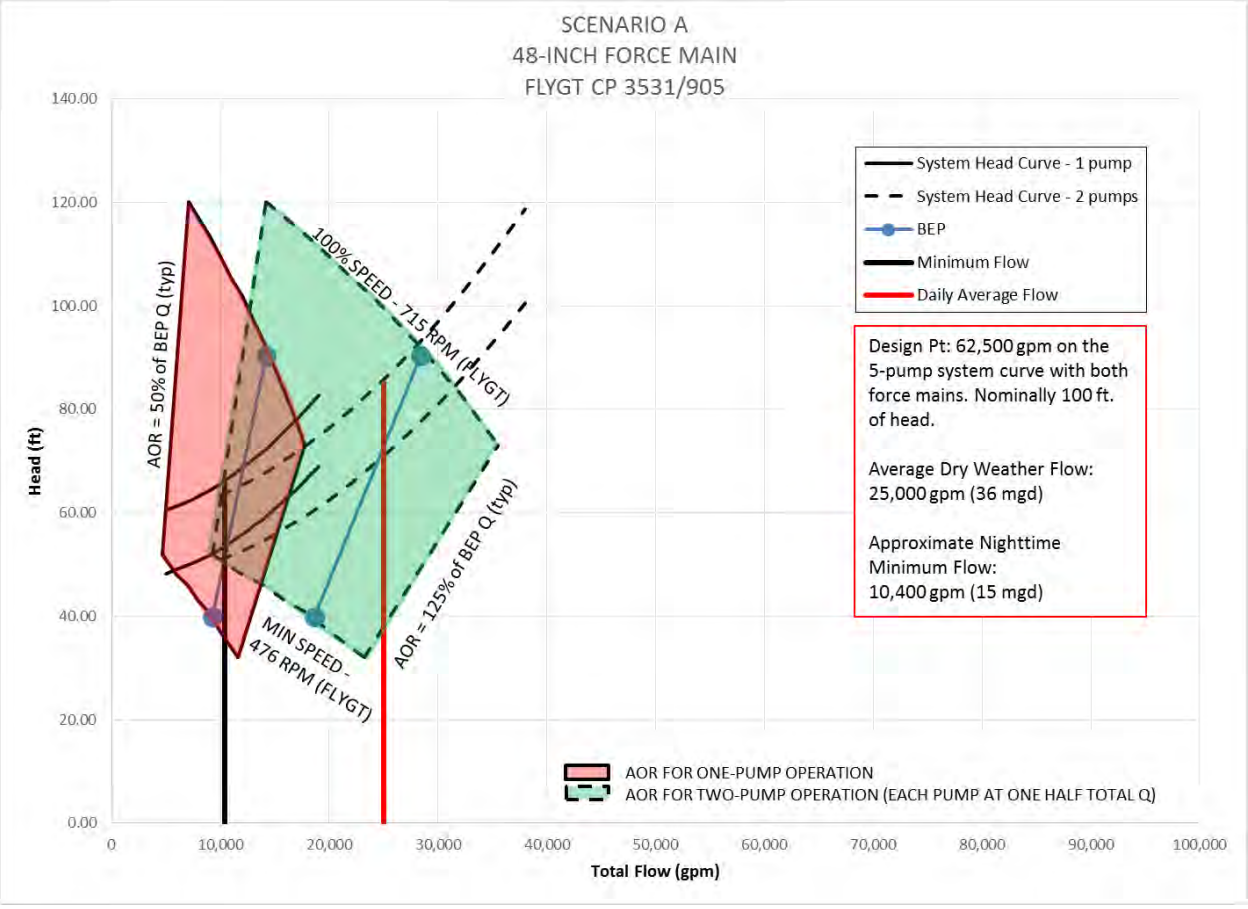

Figure 5.2 - Dual Force Main Operating - 4 & 5 Pumps (Flygt)

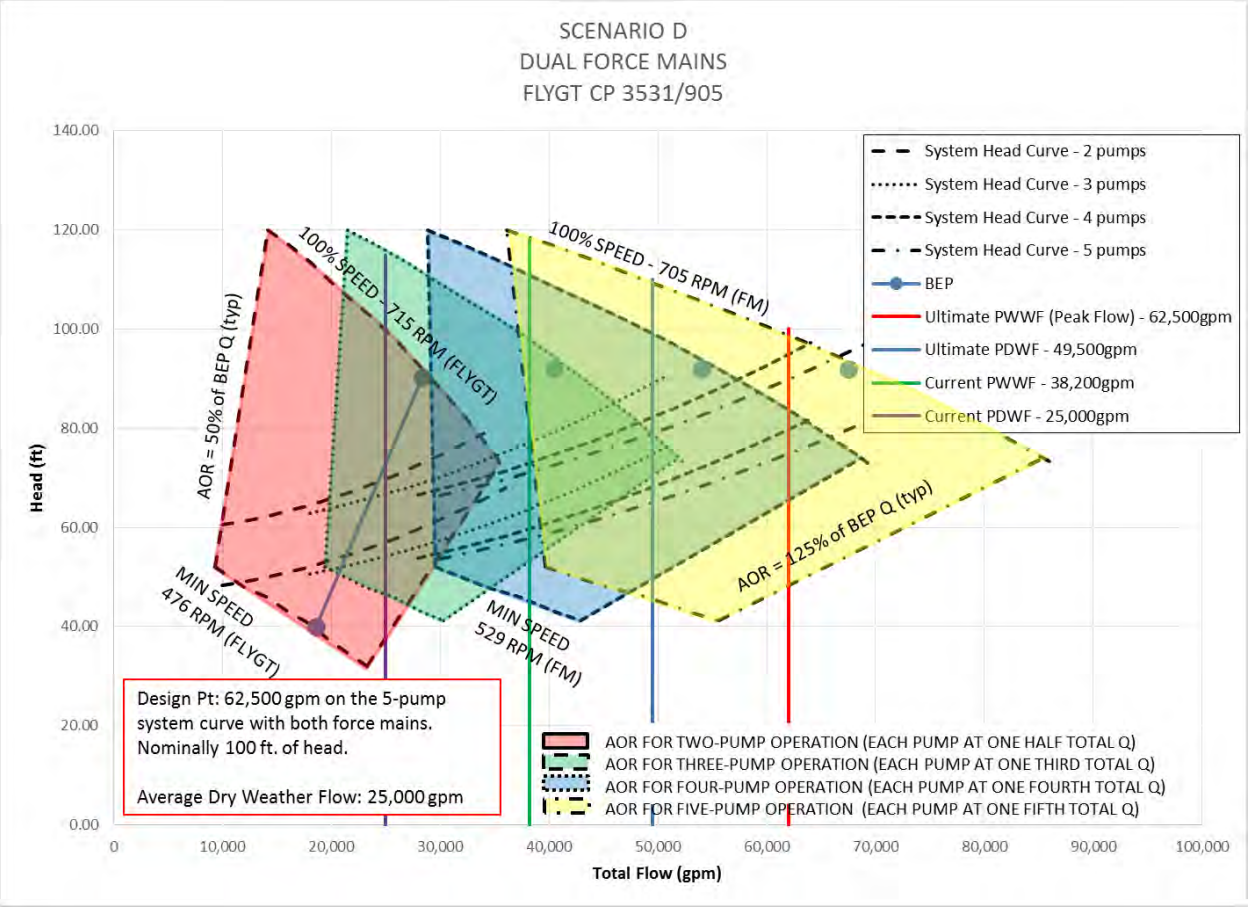

5.7.2 ABS

ABS's model AFP 5002 with a 450-HP motor was evaluated in the two figures below.

Figure 5.3 - Dual Force Main Operating - 1 & 2 Pumps (ABS)

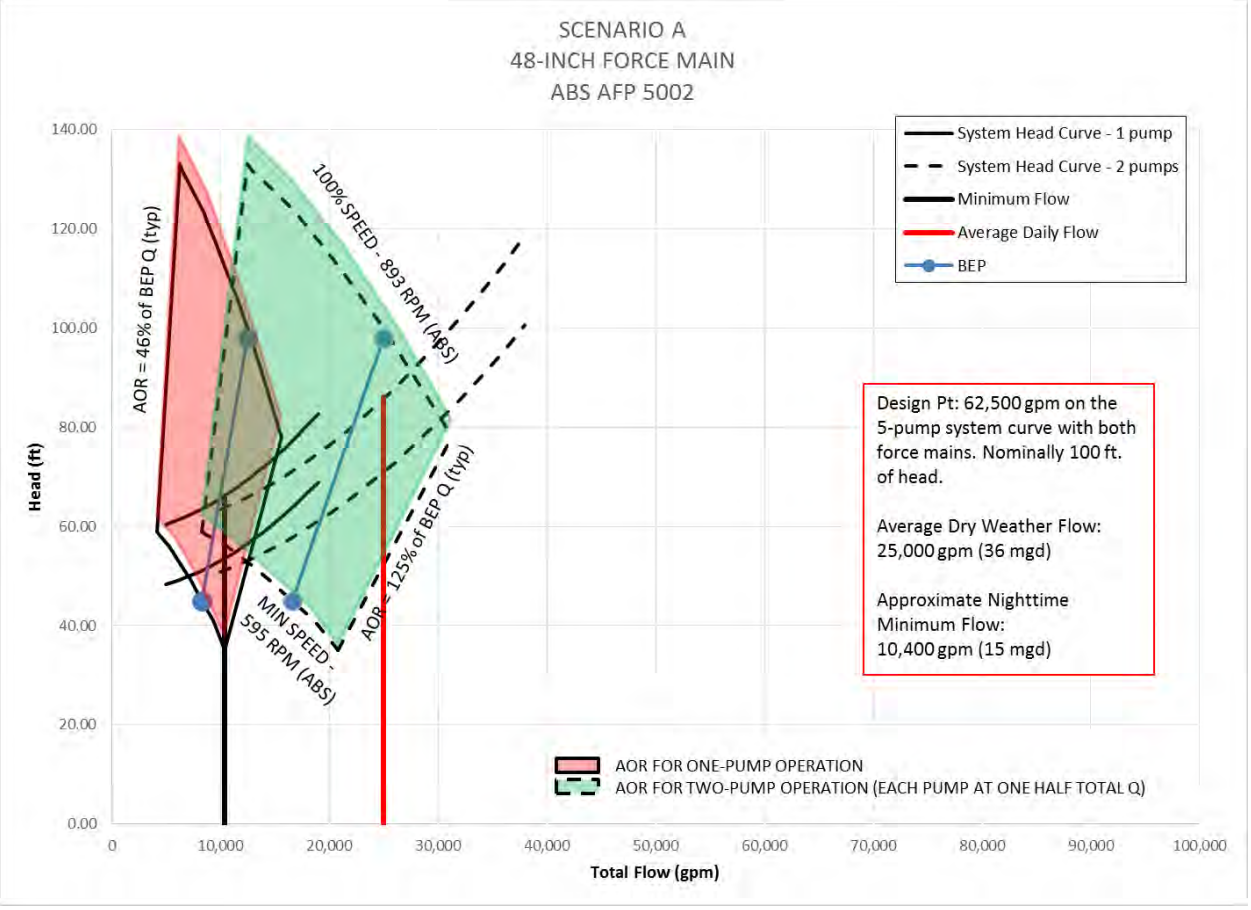

Figure 5.4 - Dual Force Main Operating - 4 & 5 Pumps (ABS)

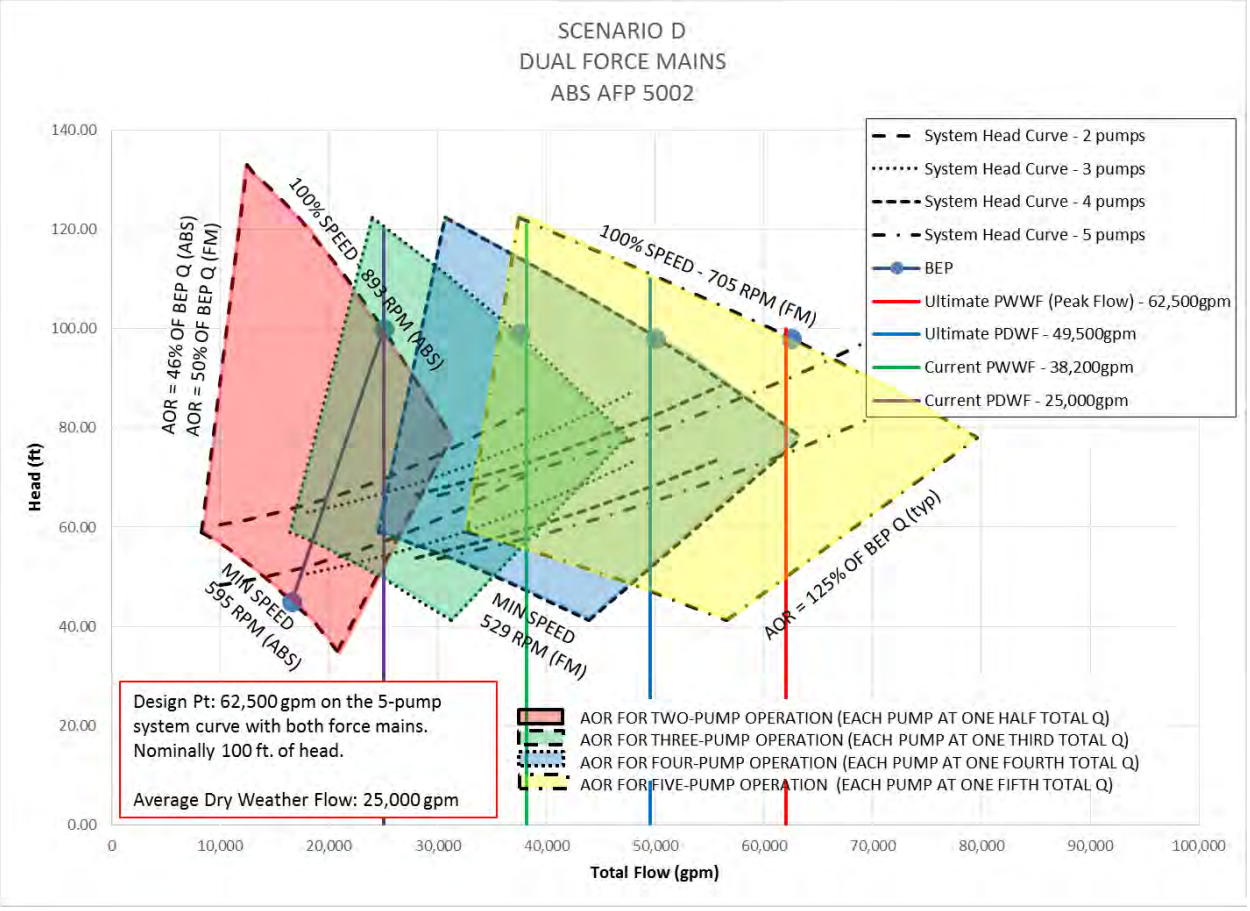

5.7.3 KSB

KSB's model KRTK 400-710/3508UNG-S with a 500-HP motor was evaluated in the next two figures.

Figure 5.5 - Dual Force Main Operating - 1 & 2 Pumps (KSB)

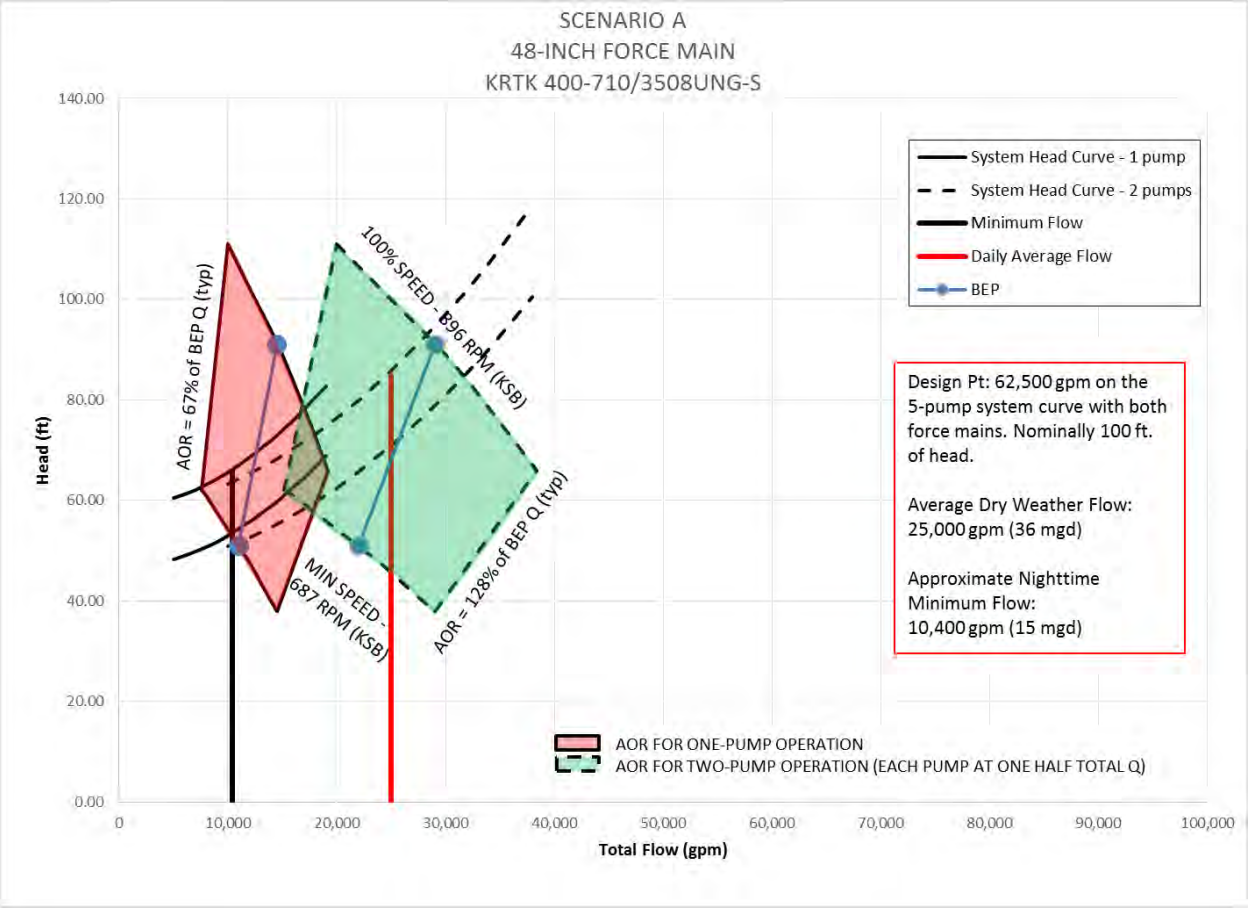

Figure 5.6 - Dual Force Main Operating - 4 & 5 Pumps (KSB)

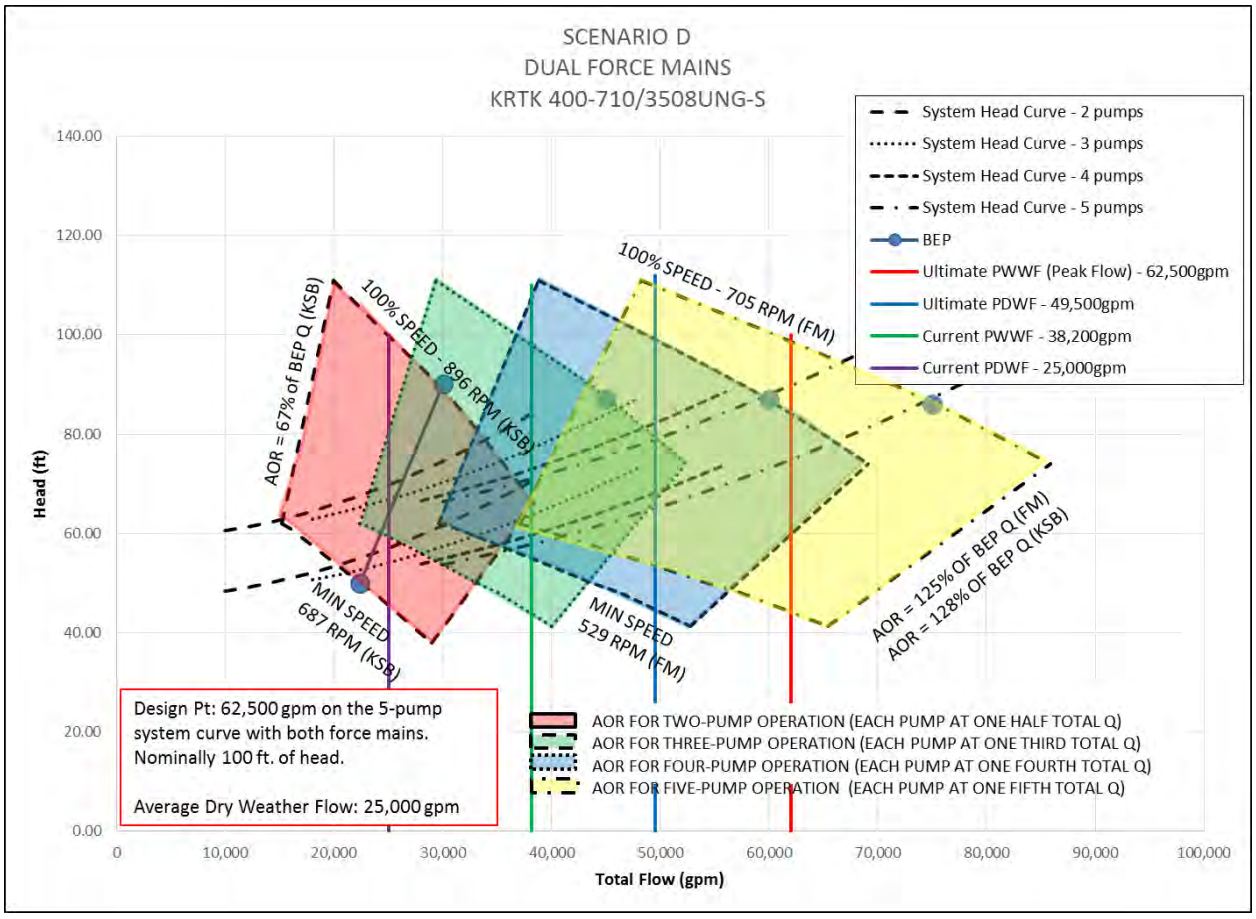

5.7.4 Pump Summary Above Peak Design Flow

Table 5.3 summarizes the flows and heads when more than five pumps are operating. Based on the information presented to ARCADIS, these conditions have not occurred at the station, but the information is provided for reference.

Table 5.3 - Flow and Head with 6, 7, & 8 Pumps Operating

Manufacturer	6 Pumps			7 Pumps			8 Pumps		
	Max Flow		Head (ft)	Max Flow		Head (ft)	Max Flow		Head (ft)
	(gpm)	(mgd)		(gpm)	(mgd)		(gpm)	(mgd)	
Flygt	78,700	113.3	95	85,000	122.4	100	91,200	131.3	104
ABS	78,700	113.3	95	85,000	122.4	99	91,700	132.1	103
KSB	78,700	113.3	95	85,000	122.4	99	91,300	131.5	103

5.7.5 Discussion

After reviewing the data and pump curves, we concluded the Flygt pump was the best selection for this application; its operating points are the closest to the BEP lines while staying to the right of the BEP lines, and it provides the best system curve coverage. The ABS and KSB model pumps are acceptable and recommended to be included in the specification along with Flygt.

Table 5.4 summarizes the motor size and best hydraulic efficiency for each pump.

Table 5.4 - Motor Information

Manufacturer	Max Required Shaft Power by Pump	Motor Rating (input power)	Best Hydraulic Efficiency
ABS	405	449	82.5%
Flygt	410	500	84.2%
KSB	440	493.5	82.3%

The “Max Required Shaft Power by Pump” column is the maximum power that the pump needs to deliver to the shaft while operating over the entire pump curve. This is what’s on the nameplate. Note that the motor may be able to deliver more power to the shaft, but this is all that would be possible while staying on the pump curve. The “Motor Rating” column is the maximum power required to operate the motor.

5.8 Pump Design Criteria

Table 5.5 summarizes the design criteria for pump selection that will be included in the pump specification for the VAPP. The specification will be based on the information provided in this section for Flygt, KSB and ABS pumps presented, and all will meet these criteria.

Table 5.5 - Design Conditions

Design Flow at First Design Point (gpm)	12,500
Design Total Head at First Design Point (ft)	100
Minimum Pump Efficiency at First Design Point (percent)	80%
Min. Sphere Diameter (in):	4
Discharge Nozzle Dia. (in.):	20
Flow at Second Design Point (gpm)	8,000
Total Head at Second Design Point (ft)	58
Flow at Third Design Point (gpm)	15,000
Total Head at Third Design Point (ft)	70
Head at Zero Flow (ft)	>145
Motor Size (hp)	500
Maximum Speed (rpm)	900
Motor Voltage/Phase/Hertz	460 V/3 Ph /60 Hz

5.9 Connection of VAPP to Manifold

There are no plans to modify any of the existing piping located in the VPP. All modifications will begin at the manifold located in Hurricane Street. The existing manifold was constructed to accommodate a connection for the VAPP on the west side, and it included an isolation valve. The east side of the manifold is planned for the connection of the new 54-inch force main.

The VAPP piping material will match the new manifold. Piping will connect to the manifold with a 42-inch flange at the west end of the manifold. Piping will continue from the manifold back to the new valve vault at the VAPP. Refer to the Yard Piping Plan in **Appendix B** for additional details.

6. Site/Civil Design

6.1 General Arrangement / Site Plan Options

The VAPP will be located just north of the existing VPP, east of the intersection of Canal Court and Hurricane Street in Venice Beach, California. The VAPP site is approximately 0.18 acres in size. Proposed improvements include a two-story, 50-foot long electrical building, a pump station with associated piping electrical and security improvements.

The electrical building is located about 18 feet east of Canal Court, with the long axis oriented North 33º31'00" West, and is set back from the north property line about 18.5 feet. The pump station is to the east of the electrical building with the same long axis orientation and is separated from the electrical building by approximately 4.5 feet. HVAC equipment for the electrical building is located on the ground north of the electrical building. Discharge piping is below grade and oriented perpendicular and/or parallel to the VAPP. The finished floor elevation of the electrical building will be determined during the next phase of design. Beyond the east side of the site, a small pocket park will be created.

Overhead powerlines will be routed south along the western property line crossing Hurricane Street and turning east along Hurricane Street in close proximity to VPP. Refer to drawings in **Appendix B** for the preliminary site plan.

6.2 Grading

The VAPP site has a high point just west of the center of the site, and drainage is to the east from the center of the proposed development and from east to west on the north side of the development. Any stormwater currently flowing from the site is in a sheet flow condition with no concentration. The preliminary site plans in **Appendix B** shows the existing contours. The site elevation ranges from approximately 4 feet to 6.2 feet across the site. Recently, the site has been used as a construction staging area for improvements to the VPP; as such, natural drainage patterns are unknown.

Proposed grading for the site will slope away from the electrical building and pumping plant for a minimum of 5 feet and be directed via swales or similar surface features towards the canal. This follows the existing drainage pattern for the majority of the site.

6.3 Utilities

The following utilities will be needed for the VAPP site: potable water, sewer, electrical and communications. Please see **Section 10**, Electrical Design for information on the electrical requirements and **Section 11** for Telecommunication Network Design. Potable water will be provided for equipment washdown purposes and

for a lavatory that will be located in the electrical building. Sanitary sewer will be provided for the washdown water and for the lavatory. Record drawings and schematics will be used to determine the best connection points to existing utilities. It is anticipated that most connections will be made in Canal Court to avoid conflict with the manifold between the pump stations.

If conflicts are found with existing utilities, the design may change alignment of the proposed utility either vertically, horizontally or both to adapt to the existing environment. Required minimum separations will be maintained. In some cases, it may be more practical to re-route the existing utility. If this is the case, the proposed relocation would be designed and require approval from the utility owner. Close coordination with the electrical design will allow the design of other utilities to avoid conflict with the electrical requirements for this project.

6.4 Site Access

Site access will be from the west via Hurricane Street. A proposed 30-foot wide access road between the VPP and the VAPP will extend for approximately 70 feet between the two sites. It is anticipated that larger vehicles would either “pull in and back out” or “back in and pull out” using the adjacent Hurricane Street and Canal Street as a turnaround. There is insufficient room at the site to provide an on-site turnaround option. Smaller vehicles will be able to execute turning maneuvers within the 30-foot access road width. A total of two parking spaces will be provided at the end of the access road.

It is also anticipated that crane access will be required via the access road, including the parking spaces, to allow a crane to be able to access both the VAPP and VPP. The surcharge loading of the crane on the pavement could be significantly larger than typical H20 design loading; therefore, the largest anticipated crane and loading will be analyzed and used in the development of pavement design. Further, the pavement design may need to provide additional protection from this loading to existing utilities within the access road. These considerations will be factored into the pavement design.

Access to the pocket park from the VAPP site will be provided via a person gate in the fence on the east side of the site.

6.5 Landscaping

Due to the site having minimal open area, minimal landscaping will be required on site. Ground surfaces that are not covered with pavement or structures, shall be covered with a ¾-inch gravel or crushed stone to provide dust and erosion control. A pocket park east of the VAPP site will be landscaped similar to the surrounding areas.

7. Site Security

7.1 Existing Condition

The existing VPP has little to no security provisions. Some personnel doors have broken handles and/or broken locking mechanisms. At one time, there were functioning limit switches on some doors to monitor their position, but most appear to be non-functioning. There is no video surveillance equipment.

7.2 Design Approach

With the advent of the new VAPP Electrical Building and the possibility of no full-time staff at the VPP or VAPP, an access control and video surveillance system will be provided for the VPP and the VAPP to protect operators working between the two sites and for remote monitoring.

Features of the Site Security design will include the following:

- Access Control and Monitoring:
  - All external personnel doors at both facilities to have keyed locks.
