THE ECOLOGY AND DISTRIBUTION OF *JUGLANS CALIFORNICA* WATS. IN SOUTHERN CALIFORNIA

A Thesis Submitted to

The Faculty of Biological Sciences

School of Letters and Science

In Partial Fulfillment for the Degree of

Master of Arts

in Biology

by

C. James Swanson

June 1967

ACKNOWLEDGEMENTS

I would like to sincerely thank all those people who helped make this paper possible. I am deeply indebted to Dr. R. J. Vogl, the chairman of my graduate committee, who untiringly gave of his time and knowledge during all of my field work. I would also like to thank Dr. W. O. Griesel and Professor R. C. Ross for their assistance and advice in their capacity as outstanding teachers and advisors.

My special thanks go to Pam, Bill, and Mike Curtis, my niece and nephews, who greatly assisted in the field work. I also appreciate the transportation and financial aid offered by Ron Swanson, my older brother, and the constant encouragement of all the members of my family.

It was my pleasure and honor to communicate with Dr. J. Thomas of the Dudley Herbarium, Stanford University, Dr. R. Thorne of Rancho Santa Ana Botanic Garden, H. K. Sharsmith of the University of California at Berkeley, Dr. M. Mathias of the University of California at Los Angeles, and Dr. B. Templeton of the Los Angeles County Museum of Natural History.

Finally, I would also like to thank Sally Golman for her illustrations; and Mrs. Jennie Nelson, Dieter Wilken, Marilyn Chase, and John Elliott.

INTRODUCTION

An ecological study of the Southern California black walnut (Juglans californica Wats.) was undertaken to determine the 1) present distribution, 2) vegetational associations, 3) age composition, 4) edaphic and climatic relationships, and 5) future of the tree. Only the more important ecological factors were investigated, and no attempt was made to ascertain the total ecology of the species. This tree was studied because the walnut is presently being eliminated throughout its range by urbanization in all of its varied forms. A record of the ecological requirements of this vanishing species might be of use in future forestry and horticulture.

No pertinent work has been completed on the tree,with the possible exception of the discussion by Jepson (1910). The walnut is endemic to Southern California and is known mainly for its use as a root-stock for the commerical English (Persian) walnut. The wood has no present economic value, and the tree has thus been ignored as a lumber source.

Extensive travel was made to determine the present distribution of the tree. In addition, information on herbarium specimens from many California institutions was utilized. Field work was carried out in two localities to determine the ecological interrelationships between the walnut and associated native species.

DISTRIBUTION

The present distribution of J. californica was determined because of the absence of recent distribution studies. Sudworth (1908) stated that the tree grew in the Santa Barbara National Forest from 800 to 4,000 feet elevation and in watersheds of the Santa Maria, Santa Ynez, Santa Barbara, Matilija, Piru-Sespe, and Newhall Rivers. He stated that its range extended to the south and west slopes of the San Bernardino Mountains up to 3,000 feet elevation, and the tree was present in Waterman Canyon at 2,000 feet. Jepson (1910) was more conservative in defining the northern limits of the species and maintained that the tree grew from Santa Barbara, Torrey, and the Ojai Valley to San Fernando and the Sierra Santa Monica, thence eastwardly along the foothills of the Sierra Madre to the San Bernardino Range and southward to the Sierra Santa Ana. A recent flora (Munz, 1959) states that J. californica ranges from Ventura County to west cismontane San Bernardino County and the Santa Ana Mountains, Orange County.

The present distribution was determined by making field surveys of all known and suspected areas of distribution and by utilizing the annotations made on herbarium specimens of the major herbaria of California (Appendix A), including Stanford University, Universities of California at Berkeley, Santa Barbara, and Los Angeles, University of Southern California, Los Angeles County Museum of Natural History, California State College at Los Angeles, Pomona College, and Rancho Santa Ana Botanic Garden. It was found that the present distribution of the native walnut extends north of Santa Barbara County (Fig. 1), with specimens located in San Luis Obispo County, inland from Cambria.

To the south and east, specimens were found along the Santa Ana River in Orange County, eastward to Riverside County, and as far east as Yucaipa in San Bernardino County. In terms of elevation, specimens ranged from near sea level at Malibu and Cypress, California, to 3,000 feet in the San Gabriel Mountains north of La Canada (Los Angeles County) and in Lone Pine Canyon (San Bernardino County).

DISTRIBUTION BY COUNTIES

San Luis Obispo County

Juglans californica was reported in the foothills east of Cambria in San Luis Obispo County (Dieter Wilken, personal communication, 1966). A survey was made of this area on March 28, 1967. Two mature trees and three saplings were found along Santa Rosa Creek, 3.2 miles east of the junction of Highway 1 and Highway 41 (Fig. 2). In addition, many seedlings were found along the creek bed, and other trees were found growing 10.3 miles east of this location. On the basis of the 1) multiple-trunked growth form, 2) number and shape of the leaflets, and 3) size and shape of the fruit these trees were classified as J. californica. Herbarium specimens were collected and placed in the herbaria at California State College at Los Angeles, Stanford University, and Rancho Santa Ana Botanic Garden. Other specimens were found growing along San Luis Obispo Creek approximately five miles south of San Luis Obispo, near the coast. These trees were multiple-trunked and were considered to be J. californica. A specimen from the herbarium of the University of California at Berkeley dated 1889 was also collected in the county (Appendix A), but the exact location was not given.

Santa Barbara County

Walnuts were found three miles east of Solvang. Other specimens were collected along Highway 101 between Santa Barbara and Carpinteria near the immediate coastline. Good stands were found along the intermittent Casitas Creek, inland from Montecito and Carpinteria. Specimens from the University of California at Santa Barbara herbarium show that the tree also grows along Jalama Creek near Point Conception at an elevation of 100 feet and near the school grounds at Figueroa Mountain Road north of Los Olivos, California.

Within the county, native walnut favors the canyon bottoms at the southeast end of the Santa Ynez Mountains and the broad, deep-soiled intermountain valleys near Los Olivos in the northwest (Fig. 3). J. californica is absent throughout most of the ranges north of Santa Barbara, due possibly to the steepness of the slopes, lack of well established soil, and severe competition by chaparral species.

Ventura County

The walnut grows well in the hills surrounding Lake Casitas and along the Sespe Creek north of Ojai. Specimens were found 14 miles north of Ojai in moist canyon bottoms. The best walnut stand in Southern California was found on the north slope of Sulphur Mountain along Santa Paula Creek, north of Santa Paula. Another smaller stand was located between Moorpark and Fillmore along Grimes Canyon Creek.

The walnut appears to be absent on the coastal plain between Camarillo and Ventura, probably as a result of the extensive agricultural use of this fertile region. In the western Santa Monica

Mountains, walnut trees were observed in the hills between Newbury Park and Lake Sherwood. In the eastern portion of the county, specimens were found in the canyons around Lake Piru and along Sespe Creek north of Fillmore, but none were found along the wide floodplain of the Santa Paula River. No specimens of J. californica were found beyond a point 14.2 miles north of Ojai. However, a single herbarium specimen exists from the University of California at Berkeley which has the annotation, "Tejon, Ventura Co., May 11, 1935," (Appendix A). The extreme northern part of the county contains the Topatopa Mountains, Mount Pinos, and Mount Frazier, whose surfaces are dominated by chaparral at the lower elevations and by coniferous species at the higher elevations.

Within Ventura County, as in Santa Barbara County, the walnut favors cool, moist canyon bottoms, north-facing slopes, and water-courses of intermittent streams (Fig. 4). Good stands of trees are the exception, most specimens being widely separated from one another.

Los Angeles County

In Los Angeles County the walnut favors the canyon bottoms of the Santa Monica Mountains on the west and the rolling foothills of the Puente Hills on the east. Several specimens were found on the ocean side of the Santa Monica Mountains in Malibu and Topanga Canyons near the town of Malibu. They grew mainly in the cool canyons with access to streams which flow during the winter months.

Farther east, the number of trees generally tends to increase from Topanga Canyon to Cahuenga Pass. Throughout this area the trees favor north-facing slopes, but specimens were also noted in the canyons

on the south side of this range. Across the San Fernando Valley, the walnut follows the remaining streams and the Los Angeles River, even though the majority of these have recently been paved with concrete. Presently there is approximately one native tree per square mile in this valley, although they are not regularly distributed.

At the eastern end of the Santa Monica Mountains walnut is present in the Griffith Park hills, where it grows almost exclusively on north and east slopes. Specimens were also found in Elysian Park and in the sheltered canyons on Mount Washington. Other specimens occur on the west side of the Arroyo Seco at Avenue 60 and on the east side at Monterey Pass. Three trees were found on the west rim of the Arroyo Seco at the eastern end of the San Rafael Hills. In the San Gabriel Mountains trees grow on northeast-facing slopes up to 3,000 feet elevation above the Arroyo Seco. This arroyo appears to have served as an avenue of dispersal in the past.

With the exception of three specimens found above Foothill Boulevard in Little Tujunga Canyon and those on the west rim of the Arroyo Seco, no trees were found in the region of Glendale, Burbank, La Crescenta, Tujunga, Sunland, or San Fernando. Included in this area are the San Rafael Hills and the Verdugo Mountains, which appear to be able to support walnut but contain no specimens. These observations agree with those of W. O. Griesel, who has made extensive collections in this region (W. O. Griesel, personal communication, 1966).

A few specimens were found northwest of San Fernando along Interstate Highway 5 between the junctions of Highway 14 and Highway 126. Specimens reported along Soledad Canyon Road on the desert side of the San Gabriel Mountains were identified as the introduced

Juglans nigra L.

No specimens were found in the Los Angeles basin proper during field or herbaria surveys. One specimen from the University of Southern California herbarium was found near the campus, but it appeared to be a planted J. californica X J. regia hybrid or J. regia L. itself. Disturbance within the metropolitan area has destroyed almost all native vegetation, making it impossible to reconstruct the walnut's past distribution.

East of metropolitan Los Angeles, walnuts were found along the railroad tracks north of the San Bernardino Freeway between Soto Street and Eastern Avenue. Additional specimens were noted in Whittier Narrows, south of El Monte. A good stand exists in the San Jose hills, west of Pomona. J. californica follows these hills north in the San Dimas-Glendora area near Puddingstone Reservoir. Herbarium specimens (Appendix A) show that along the San Gabriel Mountains east of the Arroyo Seco walnut trees have been found in Pasadena (G. B. Grant Collection, May 5, 1905), northeast of Glendora, and in San Dimas Canyon, but these localities were not personally verified.

Southeast of La Puente, walnut trees were found in the Puente Hills near Hacienda Boulevard and along San Jose Creek south of Valley Boulevard from La Puente to Spadra. Southwest of Pomona, specimens were found near the intersection of 5th Avenue and the Corona Freeway. The best stands in Los Angeles County exist along Brea Canyon Road north of the town of Brea in the Puente Hills. The trees appear to thrive on the soil developed from the sedimentary beds of these hills. They grow principally in canyon bottoms and have the characteristic

multiple-trunks (Jepson, 1910) of the Southern California species.

Within the county, J. californica appears to be somewhat restricted to watercourses, canyon bottoms and rolling foothills (Fig. 5). This is shown by the manner in which the tree follows the Santa Monica Mountains, the Los Angeles River, and the Arroyo Seco. Before disturbance occurred, the tree may have flanked the Los Angeles River south across the coastal flatlands to the port of San Pedro. The widespread presence of the tree within the county in the past is suggested by the number of streets, creeks, washes, and even a town containing the name "walnut" or "nogales" (Spanish for walnut).

Orange County

The walnut is confined mainly to the northern and eastern portions of Orange County (Fig. 6). The most abundant specimens were found along the lower or south ends of Brea Canyon and Carbon Canyon. In Brea Canyon walnuts dominate the hills surrounding the property of the Firestone Boy Scout Camp, the defunct Diamond Bar Ranch, and miscellaneous oil field lands. In Carbon Canyon chaparral prevails, with walnut generally restricted to canyon bottoms and upper plateaus. Here it does not have the density displayed in Brea Canyon.

Southwest of this area, J. californica was found near the intersection of State College Boulevard and Orangethorpe Avenue in Fullerton. Other specimens were found along the wash east of the intersection of Imperial Highway and Telegraph Road. Several trees also occur on the coastal plain near the town of Cypress. Two specimens were found along the Santa Ana River at Esperanza (near the old site of the Rancho Santa

Ana Botanic Garden). A few trees were also noted up-canyon to the Riverside County line. This area and the northern edge of the Santa Ana Mountains appear to be able to support more walnuts, but field surveys and herbarium specimens (Appendix A) revealed no other stands within the county.

Field surveys between Santa Ana and San Clemente revealed no specimens in this area. The Santa Ana Mountains, with their dense chaparral, provide a barrier to the walnut tree, yet several coastal valleys between Santa Ana and San Clemente seemingly could support the tree. The area west of Santa Ana also poses a restriction to the walnut, since it once consisted of many fresh and salt water marshes, and the soil is sandy or poorly drained.

San Bernardino County

Specimens were found along Riverside Drive east of Chino, but these may represent stump sprouts from old planted J. regia. Other trees were noted on the east side of Interstate Highway 15 between San Bernardino and Cajon Pass. A specimen from the Dudley Herbarium of Stanford University was collected by Abrams and McGregor in Lone Pine Canyon on the desert slopes of the San Gabriel Mountains on July 5, 1908 (Appendix A). A field survey in the spring of 1967 showed that walnut is still present in this area. Several trees were found in Lone Pine Canyon, 1-2 miles northwest of Lost Lake. Other trees were found on the ocean side of the range along Lytle Creek and at the mouth of Lytle Creek Canyon north of Devore Road. In addition, specimens were noted along Sevaine Canyon Creek and Deer Canyon Wash.

The trees follow these streams which meander across the floodplain below the San Gabriel Mountains.

East of San Bernardino three trees were found near Wilson Creek on the road from Mentone to Yucaipa. This location is the farthest east in California that any specimens of J. californica have been personally verified. Herbarium specimens (Appendix A) show that the tree has been found at Arrowhead Springs, Waterman Canyon, Mill Creek, Cajon Pass, San Antonio Canyon, Etiwanda, Colton, Fontana, northern Carbon Canyon, and Aliso Canyon.

Within the county, the Southern California black walnut is found only sparingly (Fig. 7). It may exist in some unsurveyed side canyons of the San Gabriel or San Bernardino Mountains. The majority of the area between Ontario and San Bernardino consists of vineyards. The soil is a coarse alluvium of rock and sand, which does not appear ideal for the growth of the walnut tree except along water courses and washes. Most of the county north of the San Gabriel and San Bernardino Mountains contains the Mojave Desert, a present limitation to the distribution of the walnut.

Other Locations

A specimen from the University of California at Berkeley herbarium has the annotation "Corona, Orange Co., March 1934." Strictly speaking, Corona is in Riverside County (Fig. 8). A field survey revealed no native trees in this area, however. In Riverside, California, several specimens of J. nigra exist, and along the wash that runs west of the University of California at Riverside several specimens of Carya were

found. From a distance these Carya specimens resemble J. californica.

Specimens from the herbaria of the Los Angeles County Museum of Natural History and Rancho Santa Ana Botanic Garden show that J. californica was introduced to Santa Catalina Island several years ago. The trees now grow in Hamilton Canyon and along the road from Avalon to the airport (Appendix A).

Distribution Summary

The Southern California black walnut shows a locally discontinuous distribution across cismontane Southern California. The transverse mountain ranges and the Mojave Desert appear to limit its extension to the north. To the west the barrier is ultimately the Pacific Ocean. The southern limits of the range appear to be the Santa Ana Mountains and the other Peninsular Ranges. Reasons for these limits are unclear, but possible factors are chaparral competition and poorly developed soils. The eastern limits appear to be the cismontane foothills of the San Bernardino and San Jacinto Mountains and the Colorado Desert.

Several factors made the distribution study difficult. In the metropolitan portions of Los Angeles and the San Fernando Valley, mass housing, freeways, and concrete river beds have destroyed many specimens and restricted the range of this species. The second problem involved the identification of native walnuts. Thirty to forty years ago much of the San Fernando Valley was occupied by groves of the English walnut (J. regia), and this species is still used extensively for a street tree. The northern California walnut, Juglans hindsii (Jeps.) Jeps., and the Southern California walnut, J. californica

were frequently root-grafted to scions of the English walnut, because of their disease resistance and root adaptations to native soils. Later when the aerial portion of the trees (J. regia)was removed or died back from neglect, sucker trunks would appear which resembled either J. californica or J. hindsii. Because of this, identification became a problem, and it was often difficult to differentiate native trees from native stock. In many parts of the San Fernando Valley Eastern black walnut (J. nigra L.) is used as a street tree. Thus, at least four species of walnut (J. nigra, J. regia, J. hindsii, and J. californica) are present in this one area. Two of these, J. californica and J. hindsii, are morphologically indistinct, thus making species identification difficult.

Native walnuts have been planted outside of their present range and appear to tolerate environmental conditions beyond their present distribution. Planted trees were observed at Clear Creek in Kern County near the town of Havilah, approximately 100 miles northeast of their present limits. At Ice House Canyon on Mount San Antonio (Los Angeles County) the tree occurs 3,000 feet above the highest elevation of natural occurrence, and planted trees have been found in Escondido (San Diego County), 80 miles south of the trees natural limits. The Arizona walnut, Juglans major (Torrey) Heller, grows well on the Mogollon Rim in the Weaver Mountains of Arizona, in canyons of the Santa Catalina Mountains, and in the washes around Nogales, Arizona. Thus, remnant stands of Juglans in the Southwest may have wider amplitudes of tolerance for climatic and edaphic factors than would be expected (Sudworth, 1908; Jepson, 1908).

Northwest of Santa Barbara County, an area exists (200-250 miles between stations at Los Olivos and Mount Diablo) which is devoid of native Juglans, with the exception of the J. californica observed inland from Cambria. This major discontinuity between the distributions of J. californica and J. hindsii has been explained by a recent investigator (H. H. Thomsen, 1963) on the basis of paleontological evidence. Thomsen maintains that from one of several possible Miocene or Pliocene ancestors present in the vicinity of the Sierra Nevadas

> "...there may have been a separation as early as Miocene time, with the result that J. californica Wats. was derived perhaps through J. nevadensis Berry, J. rupestris Engelm., J. beaumontii Axelrod emend., or other similar small-leaved, small-fruited species, which tolerated the more xeric environment of the southern parts of the United States, whereas the ancestors of J. hindsii (Jeps.) Jeps., may well have advanced coastward before the cold, following down the streams of the Central Valley, never approaching the coast beyond the edge of the fog-drip belt, retaining its mesic characters of lofty height, lush foliage, and smooth, faintly grooved flattened nut."

Local climate and physiography then allowed for the independent evolution of the two species. This is contrary to the theory proposed by Jepson (1910), which maintained that the northern specimens were introduced from Southern California by the trading of native Indian tribes.

In Southern California the native walnut appears to exist in

remnant stands occurring mainly in cool, moist areas, such as canyons of north-facing slopes and riparian woodlands. It apparently is able to move out onto the coastal floodplains by following washes and subterranean rivers. The tree's survival is perhaps aided during the summer by the frequent fogs that cover the coastal flatlands and inundate the foothill ranges (Griffith Park, Puente, San Jose, Brea, Chino, etc.) which the walnut favors. J. californica is endemic to Southern California, and its distribution is steadily being restricted.

TAXONOMY

The genus Juglans is one of two genera of the family Juglandaceae occurring in North America. The other genus is Carya, which occurs mainly in eastern United States. The family contains six genera and approximately 40 species of the northern temperate zone and the northern Andes (Munz, 1959; Good, 1947; Jepson, 1951). The generic name Juglans literally means "nut of Jupiter."

Members of the genus Juglans are deciduous trees or shrubs with alternate, pinnate, astipulate leaves and chambered pith (Abrams, 1917, 1923; Baerg, 1955). There are two species native to California. Juglans hindsii occurs in the foothill valleys around Walnut Creek and Mount Diablo near San Francisco Bay. The tree was first discovered in 1837 by Richard Brinsley Hinds, the botanist of the British Exploring Ship Sulphur (Jepson, 1910). It was considered varietally distinct from the Southern California species by Willis Jepson in 1909. Later, because of the 200-300 mile gap between the distributions of the two native California walnuts, he designated it as a distinct allopatric

species.

The Southern California black walnut (J. californica) was named by Sereno Watson in 1875; however, no type locality was cited (Watson, 1875). It is taxonomically distinguished from other species of the genus on the basis of the number and size of the leaflets, shape and margin of the leaflets, size of the fruit, growth form of the tree, and distribution. There are 11-15 (rarely 19) leaflets per leaf, and they are described as oblong-lanceolate, acute or acuminate, glabrous, finely serrate, cuneate or rounded at base (Munz, 1959; Sargent, 1922; Peattie, 1953). Juglans hindsii has 15-19 (usually 19) leaflets per leaf, which are ovate-lanceolate to lanceolate long-pointed, often falcate, serrate with remote teeth except toward the usually rounded cuneate or rarely cordate base (Munz, 1959; Sargent, 1922).

In addition to the two native species, the Eastern black walnut (J. nigra) and the English walnut (J. regia) have been introduced to the state. Natural hybrids occasionally result between these species and the native trees. Mr. Luther Burbank artificially created the hybrid J. californica X J. nigra which he called "Royal" and the hybrid J. californica X J. regia which he called "Paradox" (Jepson, 1910).

STUDY AREAS

One of the purposes of this study was to determine the vegetational composition of the few remaining good stands of the native walnut. Therefore, the two study areas were chosen because of their comparatively dense stands of trees. In this respect the areas represent

superior groves, as the walnut trees usually grow widely scattered in open formations (Sudworth, 1908; Jepson, 1910).

One study area was located on the southeast side of Brea Canyon at the boundary between Los Angeles and Orange Counties. It consists of rolling foothills, ranging in elevation from 700 to 1,400 feet. The underlying rocks of this area (Plate 1) consist of gray to white, platy siltstone with white limy concretions, and diatomaceous marine shale (Durham and Yerkes, 1964). According to the plant community concept (Munz, 1959), the flora can be described as a southern oak woodland dominated by Southern California black walnut and coast live oak. Chaparral exists on the steeper slopes.

This area is presently controlled by the Firestone Boy Scout Camp. However, in the past heavy cattle grazing has taken place, and the effects are still evident (Plate 2). Indicators of the disturbance include species of Brassica, Rhaphanus, Avena, Bromus, and Festuca (Appendix B). At present wild asses, which were released several years ago, roam and graze the hills.

The second study area was located on a north-facing slope of Sulphur Mountain along the Santa Paula Creek approximately six miles north of Santa Paula (Ventura County). The elevation ranges from 1,000 to 2,000 feet. The geology consists of dark brown grainy siltstone and marine shale. The vegetation forms a southern oak woodland, yet the understory differs widely from that found at Brea Canyon (Appendix C). The walnut forms a thick stand approaching the density of an eastern hardwood forest. Limited grazing presently occurs but signs of heavy disturbance are not yet evident.

METHODS

The vegetational analysis of the two study areas was made using three sampling techniques. Trees were sampled with circular quadrats, each quadrat one-fortieth acre in size. Twenty quadrats were placed at random in each of the study areas. The understory of shrubs and herbs was sampled with 4 twenty-five foot line-intercepts and 20 one-meter square quadrats.

At both Sulphur Mountain and Brea Canyon north-facing slopes were sampled. Trees were recorded by their specific names, and basal areas were determined. For multiple-trunked specimens of Juglans, the basal area of each trunk was recorded. Sambucus mexicana Presl. was included as a tree whenever it complied with Sargent's tree definition (Sargent, 1922). Seedlings were also counted.

In view of the large amount of Phoradendron flavescens var. macrophyllum Engelm. in Rothr. parasitic on the walnut in Brea Canyon Hills, a survey was made to determine the incidence of mistletoe. Fifty trees were selected at random. The trunks were placed in size classes according to diameter at 4.5 ft. above ground (d.b.h.), and mistletoe counts were made for each trunk (Table 1). Since mistletoe grows in clones, each clump of mistletoe was considered to be a single specimen, regardless of size.

VEGETATIONAL ANALYSIS OF THE STUDY AREAS

Brea Canyon and Sulphur Mountain differ markedly in vegetational composition, even though both areas were dominated by walnut. In Brea Canyon the tree canopy cover was approximately 40% (Table 2), and there

were no walnut seedlings present; whereas, at Sulphur Mountain the canopy cover was 80-90% (Table 4), and there was an average of 800-900 seedlings per acre.

At Brea Canyon the relative and absolute frequencies of J. californica and Q. agrifolia were coincidentally the same (70% and 30% respectively). Their relative densities of 68% and 32% and their relative dominance of 65.4% and 34.6% did not differ greatly from their frequencies.

In the understory at Brea Canyon Avena fatua showed a frequency of occurrence of 100% (Table 3), while Eremocarpus setigerus and Galium triflorum had frequencies of 75% and 70% respectively. The next most frequent species was Brassica campestris (35%), and the least frequent species were Elymus sp. (10%) and Asclepias fascicularis (5%). A. fatua and B. campestris are introduced species.

Brea Canyon can thus be described as a good southern oak woodland community. Although some species of Alnus, Platanus, and Salix grow along the creek that passes through the canyon, the area is predominately a Juglans californica-Quercus agrifolia association. The two dominant trees have a somewhat aggregate distribution with oaks occurring in the steep canyon draws and walnuts dominating the more gentle slopes, plateaus, and canyon bottoms. The Galium triflorum in the north-slope understories is replaced by Brassica, Rhaphanus, and Astragalus on the south-facing slopes.

The vegetational composition at Brea Canyon represents a typical stand of J. californica. The trees are well separated from each other and form an open forest or savanna. The absolute density (34 trees

per acre) is in sharp contrast to that encountered at Sulphur Mountain. The absolute dominance of the walnut (6,844 sq.in. per acre) is also much less than at Sulphur Mountain.

In surveying the trees at Sulphur Mountain a distinction was made between the two types of walnuts present. Here the native tree grows within five miles of large orchards of the English walnut (J. regia). On the basis of the number and size of the leaflets and texture and color of the bark, many of the naturally occurring trees (32.6%) in the study area were determined to be hybrids of the two species. They were therefore referred to as J. californica X J. regia (Jepson, 1910).

Four tree species occur at Sulphur Mountain--J. californica, J. californica X J. regia, Sambucus mexicana, and Quercus agrifolia. The native walnut and the hybrid species had relative frequencies of 51.4% and 34.3% respectively (Table 4). In contrast, S. mexicana and Q. agrifolia had relative frequencies of 8.6% and 5.7%. The absolute density of native walnuts and hybrids was 124 and 60 trees per acre. The density of walnut at Sulphur Mountain was four times as great as its density at Brea Canyon. Hybrid trees were observed at Brea Canyon also, but they were not encountered in the sampling. The densities of S. mexicana and Q. agrifolia were 6 and 4 trees per acre.

The relative dominance was 76.8% for native walnut, 7.1% for the hybrid, 0.9% for S. mexicana, and 15.2% for Q. agrifolia. J. californica had an absolute dominance of 15,326 sq.in. per acre, while the hybrid had a dominance of only 1,422 sq.in. per acre. The dominance of the native tree in this area is over twice as great as it is in Brea Canyon. Most trees at Sulphur Mountain were single-trunked, while those at Brea Canyon usually had two or more main trunks. The

absolute dominance of S. mexicana and Q. agrifolia were 164 and 3,032 sq. in. per acre.

In the understory at Sulphur Mountain Avena fatua had a 100% frequency (Table 5), while Galium triflorum had a 95% frequency. Seedlings of Juglans (60%) and Stachys bullata (30%) were next most frequent. The species encountered with the least frequency were Rhus diversiloba (20%), Ribes speciosum (15%), and Osmorhiza brachypoda (5%).

This portion of Sulphur Mountain might well be described as a Southern California black walnut forest community, because of the high frequency, density, and dominance of native walnut. The trees form a closed forest in comparison to the stand at Brea Canyon. With its verdant understory and closed canopy, the area approximates an eastern forest complex. Eastern affinities present in the understory include species of Dentaria, Elymus, Erysimum, Geranium, Lathyrus, Rubus, Sambucus, Silene, Stachys, Stellaria and Symphoricarpos.

Many species were found in only one of the study areas. At Brea Canyon significant species include Asclepias fascicularis, Encelia californica, Brassica campestris, Rhaphanus sativus, Eremocarpus setigerus, Salvia mellifera, Astragalus sp., Lupinus succulentus, Eriogonum fasciculatum, Solanum Xantii, and Nicotiana glauca (Appendix 8). Significant species present only at Sulphur Mountain include Symphoriocarpus mollis, Silene gallica, Dentaria californica, Euphorbia peplus, Geranium molle, Stachys bullata, Lathyrus tingitanus, Zauschneria cana, Ranunculus californicus, Rubus ursinus, Lithophragma cymbalaria, and Osmorhiza brachypoda (Appendix C).

PHENOLOGY

The Southern California black walnut is a deciduous tree and remains leafless throughout the winter months. Leaves appear in late January or early February, apparently depending upon the frequency and timing of the winter rains. The leaves are alternate, pinnate, and without stipules (Munz, 1959). In 1966 approximately 30% of the trees at Brea Canyon were in leaf by February 8. In 1967, 30% of the trees were in leaf on February 26.

Field studies also revealed that the timing of leaf production appears to be related to the specific microclimate of particular stands. Trees on south-facing slopes or other drier locations produce leaves as much as six to eight weeks before trees on cool, moister sites in protected canyons or north-facing slopes. Possible "ecotypes" were found in the cooler canyons on the coastal side of Topanga and Malibu Canyons and also in side canyons of the Arroyo Seco in the San Gabriel Mountains. They had a characteristic red bark differing from the usual gray to dark-brown bark of the tree (Munz, 1959; Jepson, 1909) and did not produce leaves until late March or early April. With the exception of these "ecotypes", all other trees are in leaf by early March.

The bark of young trees is gray and smooth. Older trees develop dark-brown bark which is deeply furrowed. The wood has a specific gravity of 0.4086 and weighs 25.46 pounds per cubic foot (Hough, 1899). In contrast, the wood of the Eastern black walnut has a specific gravity of 0.52 (Fuller, 1955).

The leaves remain on the trees throughout the summer months. In

late August and early September the leaflets turn yellow, then dull-orange or brown, and leaf abscission begins. Field studies have shown that two types of abscission occur. In some cases the leaflets abscise, while the leaves are still on the trees. In other cases the leaf itself abscises with the leaflets intact. The latter type appears to be more common. The tree remains leafless from early October to late January. Some trees were observed in the Griffith Park area which are artificially watered and appeared to retain their leaves until late November or early December.

Flowering begins at approximately the same time as leaf production. The flowers are monoecious (Munz, 1959), and the male catkins are evident in early February on twigs of the previous year and sometimes appear before the leaves (Plate 3). Various authors (Munz, 1959; Wolf, 1941) state that flowering occurs from April through May; however, field observation has shown that flowering usually begins in early February, except in the "ecotypes" mentioned above.

The female flowers may appear in early February at the ends of shoots of the season but usually are not in abundance until late February. Terotological flowers, usually pistillate flowers with stamens or abnormal stigmas, have been reported (Jepson, 1910), but none were observed in the field. By the middle and latter part of March the flowers are mature and wind pollination occurs.

By late April and throughout May enlargement of the fruit occurs. At this time the shell and husk are both soft and green. The fruit is drupaceous, forming a nut when mature. Field studies have shown that the mature fruits appear on their peduncles singly, in two's, or

in three's (Plate 4), although single fruits are more common. Abnormal fruit with fused husks has been found on several trees at Brea Canyon.

By the end of July the shell hardens and turns brown; however, the husks are still green, and the nut-meat is not fully developed. In early and middle September the husks turn brown, the nut-meats ripen, and fruit abscission occurs.

FRUIT AND FRUIT DISPERSAL

The fruit of J. californica has been described as being roundish, 2.5-3 cm. in diameter, with a dark brown pubescent husk, the nut globose, thick-shelled, and longitudinally shallowly grooved (Munz, 1959). In contrast the fruit of J. hindsii is 3.5-5 cm. in diameter and more faintly grooved than that of J. californica.

By September most of the fruit is ripe and abscission begins. Fruit abscission is not completed immediately, as many of the nuts remain on the tree for several weeks or months. Field surveys at Brea Canyon in the spring of 1966 and 1967 revealed that occasional trees still held some nuts from the previous season.

Several investigators mention that the fruit is used as a food source by many rodents (Wolfe, 1941; Sudworth, 1908). This fact has not been verified throughout the entire study area. At Brea Canyon dominant rodents are the Valley pocket gopher (Thomomys bottae Eydoux and Garvais) and the California ground squirrel (Citellus beecheyi

Richardson). Neither of these rodents were seen gathering or eating fruit of the native walnut. The thick shell of the nut may pose an insurmountable barrier for its use as a food source by these species. By the time the nut cracks of its own accord, fungi mycelia have usually made the nut-meat inedible.

The situation is different in the San Fernando Valley, since the Eastern fox squirrel (Sciurus niger L.) has been introduced there (R. C. Ross, personal communication, 1966). This squirrel is able to break the hard shell of the native walnut with its strong jaws. It may also aid dispersal of the nut by burying it across this valley in the remaining open lands. Western gray squirrels (Sciurus griseus Ord.) were seen at Sulphur Mountain and may aid in the burial of walnuts. The scrub jay (Aphelocoma coerylescens Bosc.) has been reported to be an inveterate uphill planter of any object resembling a sphere. This bird may play an important role in dispersing walnuts to upland sites (Grinnell, 1932).

Without the aid of birds or rodents, the main methods of dispersal for the fruit are gravity and water transport. Gravity can only provide short-distance dispersal. However, the husk of the walnut is impermeable to water, and the nut will readily float. When the walnut is transported by water, the abrasive action of streambed gravels may enhance germination. This is probably the best long-distance dispersal mechanism of the species. Except in moist situations such as the understory at Sulphur Mountain, all seedlings encountered during field surveys were found along creek

beds or river floodplains. The wet sandy soils are ideal for germination and root development of the embryo. With the advent of cement river beds in the Los Angeles basin, many seeds are undoubtedly deposited in the ocean each year. Generally, wide-range dispersal is slow for this species, but when moisture and soil conditions are proper many hearty seedlings develop.

SEEDLINGS

Sudworth (1908) stated that seedlings of native walnut were scarce and seedling habit was undetermined. He went on to note that much of the seed is eaten by rodents and carried by flood waters to places unfavorable to germination. He also concluded that the seedlings were intolerant of shade. Baker (1948) stated that in a 1948 survey of foresters 60% agreed that black walnut (J. nigra) should be classed as intolerant of shade. This corresponds to a "class four" rating according to the tolerance table set up by Zon and Graves in 1911 (Baker, 1948).

Seedlings were uncommon in the present study. They were found only in moist soils or in full sunlight along streams and creeks. They occurred along Grimes Canyon Creek between Moorpark and Fillmore, at Sulphur Mountain (Plate 5), and along Santa Rosa Creek inland from Cambria in San Luis Obispo County. In contrast, Brea Canyon contains an almost pure stand of J. californica, yet no seedlings were found here in two years of field work.

An area at Sulphur Mountain was selected in order to study the degree of shade tolerance for the species. The area was ideal for this purpose, as it had a tree canopy cover of 80-90%. An average of 800-900 seedlings per acre were found. These figures are admittedly out of proportion for the entire area, because other portions of Sulphur Mountain contained only 100-150 seedlings per acre. Tree squirrels and scrub jays present in the area have apparently enhanced fruit dispersal. Twenty first-year seedlings were marked in the spring of 1966 and rechecked in the spring of 1967. These seedlings occurred

directly under the tree canopy. All the marked seedlings had survived and showed vigorous growth.

An experiment was carried out to test the germination percentage of native walnut. Many trees of a temperate zone origin need a cold treatment for enhanced germination (U. S. Dept. Agric., 1961). Therefore one group of 20 nuts was stratified at 0^{o}-5^{o}C for three months and then placed in seedbeds in a greenhouse. Another group of 20 nuts (unstratified) was immediately placed in the greenhouse. By April of 1967, 10% of the unstratified nuts and 20% of the stratified nuts had germinated. The walnut does not receive freezing temperatures in its native habitat; however, the temperature does approach 0^{o}C during many winter nights in Southern California (and temperatures below 0^{o}C are not really essential for stratification).

When the seed does germinate, the cotyledons remain within the nut shell (Wolf, 1941). The shell itself splits partially along the mid-line allowing the hypocotyl and epicotyl to elongate. Field studies indicate that this splitting takes place by way of a physical drying and contraction of the two halves of the shell or through the aid of the mycelia of various fungi. When carried down-stream, the outer husk is worn off, and the shell of the nut may be split by physical abrasion. The developing embryo probably also exerts pressure from within the shell, as it begins to imbibe water.

As growth of the seedling occurs, a characteristic U-shaped bend appears in the root just below the point of emergence from the shell. The nut shell remains attached to the seedling throughout most of the first year's growth (Plate 6). The initial leaves are pinnate, but

vary in number and shape of the leaflets. On the basis of the field work carried out at Sulphur Mountain it is felt that this species is either shade tolerant or else the cooler temperatures and high humidity or soil moisture under the tree canopy outweigh the effects of shade on the seedlings. The basic requirement for germination is apparently moisture.

PRECIPITATION

The amount of annual precipitation in Southern California varies from place to place and from year to year. For many plant species the total annual rainfall may be critical, while for others the timing of the rains is most significant (Went, 1949). The native walnut appears to compete directly with chaparral species Quercus agrifolia and understory species for the limited water available throughout most years. Its winter-deciduous habit apparently offers no advantage, for in Southern California the growing season occurs during the rainy winter and spring months.

Rainfall data for the two study areas was secured for the past ten-year period (Fig. 9). At the Ojai recording station near Sulphur Mountain relatively high amounts of rainfall occurred in 1958 (31.3 inches), 1962 (24.8 inches), and 1965 (29.6 inches). At the Yorba Linda station near Brea Canyon, rainfall during the ten-year period never exceeded that at Ojai. The average difference in precipitation for this period at the two stations was 7.58 inches (U. S. Dept. Commerce, 1961, 1962, 1963, 1964a, 1964b, 1965).

Precipitation appears to be particularly important for germination and subsequent growth of seedlings. The husk of the walnut is impermeable to water, and only after it is broken or removed will water uptake occur. Field studies showed that seedlings at Sulphur Mountain were 1-2 years old, while no seedlings were found at Brea Canyon. When precipitation records are correlated with seedling age and occurrence, it appears that germination takes place only in years of higher than average rainfall (25-30+ inches per year). Survival of seedlings during the first years of growth also depends on subsequent precipitation.

The amount of annual rainfall may affect the growth form of the trees at the two study sites. Most of the trees at Brea Canyon are multiple-trunked (94%), of old age, and frequently show branch-wilt due to long periods of drought. In contrast, the trees at Sulphur Mountain are mostly single-trunked (64%), hearty, and without branch-wilt.

This species is able to survive in the semi-arid Southwest perhaps by persisting through years of low rainfall, until years of higher rainfall when it is able to reproduce. It may also compensate for the limited rainfall by being restricted to local sites with surface springs, high water tables, or adjacent creeks. A related species from Arizona and New Mexico, Juglans microcarpa Berlandier, has been classed as a phreatophyte (Robinson, 1958).

SOIL SITE REQUIREMENTS

Although some authors state that native walnut grows in alluvial washes (Jepson, 1910; Sudworth, 1908), they all agree that the best growth is obtained in areas with deep soils. Auten (1945) stated that for Eastern black walnut, soil with slow drainage and excessively dry soils should be avoided. Clay and silty clay are not nearly as desirable as are sandy loams, loams, and silt loams. Lime-derived acid soils are best for the tree (Auten, 1945; Curtis, 1959; U. S. Dept. Agric., 1965).

Field surveys have shown that the walnut grows consistently in areas with a common bedrock type, with only minor exceptions. Rock samples were taken at Brea Canyon, Monterey Pass (Arroyo Seco), Piru Creek, Sulphur Mountain, Wheeler Springs (north of Ojai), and Lake Casitas (Plate 7). In each of these areas the predominant rock type is diatomaceous or non-diatomaceous shale and limy siltstone. This fact may indicate a high calcium requirement for the native tree. Exceptions to this rock type are noted in the San Fernando Valley where the tree admittedly grows along alluvial washes. Another exception exists in the San Gabriel Mountains above La Canada, where the tree grows over igneous granitic bedrock. The non-calcareous sites all had water immediately available, however.

The root system is directly affected by the soil and rock type. In sandy areas or regions with deep soils, much branching of the root system occurs. In areas with coarser soils or alluvium, thick taproots develop.

FIRE HISTORY

It was recognized in the early 1900's (Jepson, 1908, 1909) that native walnut resprouts after fires. Field studies show that most trees are multiple-trunked. The walnut develops a basal plate or "grub" just below the ground. This serves as a reservoir for carbohydrates and over the years attains tremendous proportions. When aerial portions are injured due to cutting or fire, the tree sends up numerous new shoots from this basal plate.

In the field, old trees were found with as many as 17 main trunks (Table 1). In growth form, these trunks arch out and hang low to the ground at their periphery. Jepson (1910) mentioned this habit when he described a tree from the upper Ojai Valley which had a crown diameter of 92 feet, and all the lower limbs crept on the ground. Since most walnuts occur in southern oak woodland communities with a grass understory, grassland fires have undoubtedly had a pronounced effect on increasing the number of main trunks by killing the older trunks and burning off the accumulated litter on the ground. The bark of the tree is thin and not fire resistant. Thus, fires have an apparent pruning effect on older trees.

Several problems are encountered when trying to correlate the fire history of this species. City and county fire records are inadequate in the areas concerned. Most fire stations keep records for only five or ten years. There are no nature preserves for the native walnut at the present time. Age determinations for the tree are difficult because of the high incidence of heart-rot in the various trunks of older trees. Therefore, little correlation can be made

between the number and age of the trunks and the past fire history.

AGE OF THE TREE

Sudworth (1908) stated that the native walnut is a very rapid growing tree in youth and gives evidence of being short lived, probably not exceeding 150 years. He found that trees from 12 to 15 inches in diameter were from 13 to 17 years old, and one tree 15.5 inches in diameter showed an age of 15 years.

Jepson (1910) mentioned that the largest trees average 25-50 feet in height and measure four to nine feet around the trunk at one foot above the ground. He stated that the largest trees were found in an area near Covina known locally as Walnut Wash. A search of the West Covina-Covina area known today as Walnut Wash indicates that these trees have since been eliminated. Wolf (1941) in speaking of J. californica planted at Rancho Santa Ana, stated that trees from 7 to 12 years of age attained a height of over 20 feet, while volunteer seedlings which sprang up in favored spots had almost equalled this growth in three or four years.

Attempts were made to ascertain the age of the main trunks of native walnut trees. An 18-inch Swedish increment borer was used in this work. Approximately 30 trees were bored. One of the main difficulties in attempting age determinations for these trees is that almost all older walnut trunks are attacked by wood-boring beetles, termites, and fungal heart-rot. Accurate age determinations are therefore impossible. Only minimum ages were obtained.

Ten successful increment borings were made, and the data from these samples are presented in Table 7. These trunks were bored as close to ground level as possible, and basal areas and diameters were recorded. The number of rings per inch varied from 9 to 21. Trees with basal areas of 26 and 28 square inches had minimum ages of 17 and 26 years respectively, while trees with basal areas of 104 and 154 square inches had minimum ages of 62 and 68 years. These represent the youngest and oldest trees sampled.

Microclimate and edaphics play an important role in growth rates and are responsible for the varying sizes of annual rings within the same trunk or for comparable rings on different trees. Further work is necessary to determine the ages of the various trunks of each tree and compare their growth with precipitation and temperature records of the past. No such attempt was made in the present study. More work with tree ring analysis is needed before an age/basal area growth curve can be constructed with any accuracy for the native walnut.

MISTLETOE INCIDENCE

It has been established that Phoradendron flavescens variety macrophyllum Engelm. in Rothr. is host specific and parasitizes species of Platanus, Populus, Salix, Fraxinus, Juglans, Prosopis, and Diospyros (Munz, 1959). Field surveys have shown that while some areas containing J. californica are heavily infested with this species, other areas are virtually without mistletoe.

The walnut trees in Brea Canyon are heavily infested with this species. A survey of 50 trees was made to determine the extent of

this infestation (Table 1). The exposure of each host tree was recorded during the field work. Since the number of trunks per tree had a range of 1-17, mistletoe counts were made for the main trunks of each tree, rather than total counts per tree. A total of 211 main trunks were sampled, and these trunks were parasitized by 1,926 individual clones of mistletoe (Table 1).

Trunks with diameters of 0.0-3.0 inches made up 9.9% of the trunks surveyed, yet they contained only 1.4% of the mistletoe. Trunks with diameters of 3.1-6.0 inches made up 29.3% of those surveyed and contained only 8.8% of the mistletoe. Trunks with diameters of more than 12.0 inches made up only 7.8% of the survey yet contained 31.3% of the mistletoe. This same group contained the most mistletoe per trunk, averaging 40.1 clones.

This study indicated that generally the larger the trunk diameter, the greater is the mistletoe infestation. Data on tree exposure showed that this factor was insignificant. Mistletoe is apparently disseminated chiefly by birds and involves chance dispersal. Over the years the larger (and generally older) branches would be more heavily infested than the smaller (younger) branches.

The effects of P. flavescens on the walnut tree are great. As the haustoria of the parasite penetrate the branches of the tree, they produce abnormal swellings and alter the growth of the woody tissues. Some of these swellings are the size of insect galls, while others attain much larger proportions (Plates 8, 9). Some branches attacked by mistletoe had sent out numerous new shoots from the affected areas. In other cases mistletoe at the tips of branches had caused a club- or knuckle-shaped callous to appear, thus ending any further linear

growth of the branch.

There may also be physical effects on the direction of growth caused by the weight of many clones on a branch. The older tree limbs, which are already considerably weakened by heart rot, may be subject to breakage under the added weight of the mistletoe. Two average-sized clones were cut from a single branch, and they weighed 1,300 and 1,125 grams, for a combined weight of 2,425 grams (5.34 pounds).

Species of the genus Phoradendron possess chlorophyll and are able to carry out limited photosynthesis (Fuller, 1955). This fact correlates well with the general field observation that most mistletoe was restricted to the periphery of the branches,where they may obtain sunlight (Frontispiece). In this peripheral position the mistletoe can have a pronounced effect on the morphology and general growth form of the walnut tree.

JUGLONE INHIBITION

It has long been known that species of Juglans produce a natural growth inhibitor (Daglish, 1950; Davis, 1928; Went, 1965). Daglish mentioned an amorphous compound $C_{16}H_{18}O_8$ which was isolated from extracts of the walnut (J. nigra). This compound yielded glucose and α-hydrojuglone on hydrolysis. Further chemical and spectroscopic evidence suggested that this compound was the 5-glucoside of 1:4:5-trihydroxynaphthalene.

Experiments were carried out to determine whether juglone was present in the native walnut and to determine the effects of extracts

from various plant parts on the seeds of four garden plants. Seeds of carrot, cucumber, radish, and tomato (Northrup King brand) were placed in petri dishes and treated with distilled water and extracts from the husks, roots, and leaves of the native walnut.

When the extracts were prepared, it was noted that the walnut husks were impermeable to water until they were crushed, and when crushed they emitted copious amounts of dark brown stain, presumably containing juglone. Some of the husk extract was boiled to determine if the contents were heat labile. The petri dishes were checked every 24 hours to determine germination success.

The results of the distilled water control showed that the vegetable seeds were at least 90% viable (Table 6). Results of the boiled walnut husk extract showed that all contents were apparently heat labile, as the germination percentages approached or equalled those of the controls. The unboiled husk extract inhibited the germination of all the tomato seeds and all but 10% of the carrot seeds over a seven-day period. Little or no inhibition occurred with the cucumber and radish seeds indicating differential inhibition on the part of juglone.

Walnut roots of seedlings were cut into small sections and placed in two samples. One sample was leached for 24 hours in distilled water. The other sample was placed directly in petri dishes unleached and distilled water was added to this dish. The root extract from the first sample exhibited only minor inhibition on the carrot and tomato seeds and little or no inhibition for the cucumber and radish seeds. The unleached roots from the second sample showed excellent

inhibition up to 72 hours; thereafter, mold developed in all cultures.

Finally, abscissed leaves were leached, and the extract was placed on the seed cultures. Mold developed within 24 hours in all samples. Three successive attempts in separate petri dishes gave the same results. The ubiquitous nature of soil fungi and mycorhizae associated with walnuts and filberts has been noted (Schuster, Stephensen, and Evenden, 1944). Although the specific fungi were not identified, these investigators stated that the mycorhizae are always present, regardless of pH or soil type.

It has thus been demonstrated that a differential growth inhibitor, presumably juglone, is present in varying concentrations in several organs of the native walnut. A determination of the specific chemical make-up of the inhibitor was felt to be beyond the scope of this study. Likewise, data on the exact concentrations of the inhibitor from various plant parts was not determined, but each extract was obtained by leaching the husks, leaves, or roots for the same time period (24 hours) in distilled water. Also, since no special leaching techniques other than distilled water treatment were employed, it is assumed that this same process would take place in nature.

The presence of a natural growth inhibitor allows the walnut an advantage in its competition with other trees, chaparral species, and herbaceous understory species. The fact that the greatest inhibition occurred with the extract of the walnut husks indicates a unique survival mechanism for walnut seedlings. This is supported by the observation that the inhibitor is apparently only emitted after

the husk has been crushed or removed, so that release of juglone and germination occur together.

DISEASE AND DROUGHT RESISTANCE

The native walnut has attained some degree of disease resistance. It was commonly used as a root-stock for scions of the English (Persian) walnut, because of its resistance to the attacks of the oak root fungus (Jepson, 1910; Bailey, 1928). The roots are also better suited to Southern California soils than those of the English walnut.

Young walnut trees are hearty and exhibit rapid growth. After the tree reaches 20 to 30 years of age, however, it commonly develops heart-rot and becomes easily infested with bark beetles, termites, and fungi. Basal plates on some of the older trees at Brea Canyon were heavily infested with the bracket fungus Pleurotus ostreatus Jacq. Attacks by this fungus and Armillaria mellea Vahl. are apparently very common on species of Juglans in the eastern United States, and infestations are referred to as "mushroom root rot" (U. S. Dept. Agric., 1953). Older branches appear more susceptible to attacks by mistletoe than younger branches, and the mistletoe often results in branch damage and breakage.

Wolf (1941) stated that J. californica is probably the most drought resistant of the various kinds of walnuts planted in Southern California. H. W. Shepherd (in McMinn and Maino, 1935) included the tree in lists of drought-tolerant and heat-tolerant trees native to California.

Field surveys during 1966 at Brea Canyon revealed that the walnut will succumb to considerable branch-wilt, when spring rains are

followed by a hot, dry summer. The leaflets wilt while still attached to the petiole, and leaf abscission does not occur. This is a temporary condition, for by the following spring these leaves have abscissed and are replaced by new leaves. When entire branches or trunks are removed from the tree, the walnut shows considerable vitality by developing numerous resprouts in the affected area.

Open-grown trees are susceptible to mistletoe and heart-rot. Older branches of the tree break off and add to the accumulated fuel of the understory. When fires occur in walnut stands, they destroy the accumulated fuel, mistletoe, and heart-rot trunks, leaving behind a clean growth of rejuvenated trees with many resprouts.

FUTURE OF THE TREE

Examination of the paleontological record for California walnut helps one predict the future of this species. Cain (1944) mentioned that woodland elements containing species of Juglans were present across much of the Southwest during the Pliocene in areas now occupied by deserts. The predecessor of J. californica was probably J. nevadensis Berry (Axelrod, 1939, 1950a, 1950b; Condit, 1944; MacGinitie, 1941) which occurred in the Mount Eden Flora near Mount San Jacinto and the Truckee Flora of the Northern Sierra Nevada-Great Basin region. These were Tertiary Floras of the middle Pliocene, which were scattered during periods of mountain up-lift. The distribution of J. californica apparently underwent several local accordian movements during more recent (Pleistocene) periods of glaciation.

These trees have survived in the summer-foggy coastal valleys and canyons of the Santa Monica Mountains and the Puente Hills. The walnut is now endemic to Southern California (Munz, 1935).

If the climate of future years should be warmer and more arid than in the past (Clark and Stearn, 1960; Flint, 1957), the walnut will perhaps migrate to the north or to higher elevations. Possible pathways for these movements include the Southern Coastal mountain ranges north of the Los Angeles basin, the Tehachapi Mountains, the Sierra Nevadas. Since native walnut presently occurs in canyons of the San Gabriel and San Bernardino Mountains, the tree would probably advance to higher elevations in these ranges.

The tree's distribution is presently being restricted by man. Unfortunately, walnut is located on economically valuable real estate adjacent to spreading urban centers. Many of the better stands occur on land now being converted into residential areas, such as the Diamond Bar section of Brea Canyon (Plate 10) and the Santa Monica Mountains from Cahuenga Pass to Malibu Canyon. Another fine stand of walnut is being removed in the San Jose Hills west of Pomona, to be replaced by a cemetery. Many of the trees mentioned by Jepson (1910) have long since been eliminated. The only stand that is presently being protected is located at the lower end of Brea Canyon at the Firestone Boy Scout Camp.

The bulldozing and cementing in of the river beds of the San Gabriel, Rio Hondo, and Los Angeles Rivers have destroyed existing stands and presently restrict the distributional expansion of this tree. Smog and other forms of air pollution interfere with the

physiology of many trees in Southern California (Kramer and Kozlowski, 1960), including J. californica. The reaction of unsaturated hydrocarbons with the ozone in the atmosphere reduces photosynthesis and increases respiration. Todd (1958) feels that smog has direct effects on other growth processes of trees.

Grazing is extensive in areas where good stands exist and may eliminate walnut seedlings. With increasing aridity, chaparral species are better able to compete with the native walnut. The winter-deciduous habit of the tree serves no apparent purpose, for in California the growing season occurs during the winter months. If the tree were to revert to a summer-deciduous habit in the distant future, its chances of survival might be greatly enhanced. Severe restriction or extinction of the species appears to be a more probably fate, however.

SUMMARY AND CONCLUSIONS

The Southern California walnut was studied over a two-year period from an ecological standpoint. Its present distribution was ascertained and compared with that of the past. Major factors affecting the distribution were determined, and from this information the future of the tree was predicted. The interrelationships of various edaphic, climatic, and biological agents were evaluated with regard to their effects on the tree. The phenology of the native walnut was observed and recorded. As a result of this study, the following conclusions can be made:

1) The specimens found along Santa Rosa Creek inland from Cambria in San Luis Obispo County extend the range of the tree approximately 100 miles beyond the reported northern limits for the species.

2) In terms of elevation, the tree can grow from near sea level to 3,000-3,500 feet.

3) Planted trees found in unnatural locations indicate that the native walnut may have greater amplitudes of tolerance for climatic and edaphic factors than might be expected.

4) The distribution of the tree is presently being restricted by the urbanization of Southern California. The tree is naturally restricted to cool canyon bottoms, riparian woodlands, or summer-foggy coastal flatlands with deep, well-established soils.

5) The number, size, and shape of the leaflets appear to be the best taxonomic characters for field identification; however, variation in these factors has been noted.

6) The native walnut will apparently freely hybridize with

several other species of Juglans introduced to Southern California, including J. nigra, J. regia, and J. hindsii. The common hybrids appear to have no ecological site-preference but may require more moisture than J. californica.

7) Because the tree will readily hybridize with other species, some doubt is cast on the contention that it is a species distinct from J. hindsii. The only valid criterion for this distinction is the completely allopatric nature of the distributions for the two species.

8) The walnut usually grows in southern oak woodland communities, in a Juglans californica-Quercus agrifolia association.

9) The understory of typical stands of walnut is usually disturbed and made up of introduced grasses and herbaceous annuals.

10) The walnut will readily stump sprout after fires. The bark is not fire resistant. The ability to resprout assures the tree's place in fire-swept Southern California. Fire may serve to rejuvenate disease weakened trunks.

11) Vegetative reproduction by means of basal stump-sprouts may partially compensate for the lack of sexual reproduction.

12) Throughout Southern California, sexual reproduction of the tree appears to be much less than its potential. The main factor which restricts the germination of seedlings is apparently lack of sufficient rainfall.

13) The walnut grows consistently on soils with sedimentary bedrock of limestone or siltstone and apparently has a high calcium requirement.

14) In spite of the results of past work on species of Juglans, the native walnut was found to be quite shade tolerant, or else the

moisture content of the particular micro-niche was enough to outweigh the effects of shade on the seedlings.

15) The husk of the walnut is impermeable to water, and the best dispersal mechanism for the nuts is water transport, aided by gravity.

16) Native walnut is apparently not used as a main food source by any of the rodents of the understory. In some areas, squirrels and scrub jays may play a role in the tree's reproduction by burying the nuts.

17) The particular micro-climate of each tree has tremendous effects on its growth form. "Ecotypes" may result from the conditions present in the various micro-environments.

18) Heavy infestations of mistletoe which affect growth form are present in some stands of native walnut, while others are free of this parasite.

19) Juglone was found to be present in various organs of the tree, and this chemical inhibited the growth of several garden plants. Concentrated amounts of juglone are emitted at the time of germination and may eliminate plant competition for an extended period of time.

6. " " -sedimentary hills with Quercus agrifolia north side Puente Hills opposite Carbon Canyon, San Bernardino Co., June 22, 1932.
7. " " -Aliso Canyon, Rancho Santa Ana, San Bernardino Co., April 14, 1928.
8. " " -Aliso Canyon, Rancho Santa Ana, ca. 600 ft. elev., San Bernardino Co., Jan. 8, 1944.

Appendix A. (cont.)

Santa Catalina Island

L. A. Co. Museum Herbarium:

1. J. calif.-Hamilton Canyon, elev. 200 meters, Santa Catalina Island, May 12, 1931.

Rancho Santa Ana Herbarium:

1. J. calif.-introduced to Catalina Island, chaparral near circle on summit road from Avalon to airport, elev. ca. 300 ft., Santa Catalina Island, May 11, 1965.

Specimen annotations are verbatim.

Appendix B. Species List Arranged by Plant Families - Walnut Study Area, Brea Canyon

1. Anacardiaceae:

   Rhus diversiloba T. and G.

   R. integrifolia (Nutt.) Benth. & Hook.

   R. laurina Nutt. in T. and G.

   R. ovata Wats.

   Schinus Molle L.

2. Amarantheaceae:

   Amaranthus graecizans L.

3. Amaryllidaceae:

   Brodiaea pulchella (Salisb.) Greene

4. Asclepiadaceae:

   Asclepias fascicularis Dene. in A. DC.

5. Betulaceae:

   Alnus rhombifolia Nutt.

6. Caprifoliaceae:

   Sambucus caerulea Raf.

7. Caryophyllaceae:

   Stellaria media (L.) Vill.

8. Compositae:

   Artemisia californica Less.

   Baccharis pilularis ssp. consanguinea (DC.) C.B. Wolf

   Cirsium vulgare (Savi) Ten.

   Encelia californica Nutt.

8. Compositae (cont.):

Gnaphalium palustre Nutt.

Hemizonia fasciculata (DC.) T. & G.

Senecio Douglasii DC.

Sonchus oleraceus L.

9. Convolvulaceae:

Convolvulus arvensis L.

10. Cruciferae:

Brassica campestris L.

Capsella Bursa-pastoris (L.) Medic.

Lepidium nitidum Nutt.

Nasturtium officinale R. Br.

Rhaphanus sativus L.

11. Cucurbitaceae:

Cucurbita foetidissima HBK.

Marah macrocarpus (Greene) Greene

12. Euphorbiaceae:

Euphorbia albomarginata T. & G.

Eremocarpus setigerus (Hook.) Benth.

13. Fagaceae:

Quercus agrifolia Nee

Q. dumosa Nutt.

14. Gramineae:

Avena fatua L.

Bromus sp. L.

Elymus sp. L.

14. Gramineae (cont.):

Festuca sp. L.

Poa annua L.

15. Juglandaceae:

Juglans californica Wats.

J. californica X J. regis ex Burbank

16. Labiatae:

Lamium amplexicaule L.

Marrubium vulgare L.

Salvia mellifera Greene

Trichostema lanatum Benth.

17. Lauraceae:

Umbellularia californica (H. & A.) Nutt.

18. Leguminosae:

Astragalus sp. L.

Lotus Heermanii (Dur. & Hilg.) Greene

Lupinus succulentus Dougl. ex Koch.

Medicago lupulina L.

Melilotus indicus (L.) All.

19. Lemnaceae:

Lemna sp. L.

20. Loranthaceae:

Phoradendron flavescens var. macrophyllum Engelm. in Rothr.

21. Meliaceae:

Melia Azedarach var. umbraculiformis Berckmans

22. Papaveraceae:

Dendromecon rigida Benth.

Eschscholtzia californica Cham.

23. Plantagineaceae:

Plantago major L.

24. Platanaceae:

Platanus racemosa Nutt.

25. Polygonaceae:

Eriogonum fasciculatum Benth.

Polygonum aviculare L.

Rumex crispus L.

26. Portulacaceae:

Montia perfoliata (Donn) Howell.

27. Primulaceae:

Anagallis arvensis L.

28. Pteridaceae:

Pteridium aquilinum var. *lanuginosum* (Bong.) Fern.

29. Rosaceae:

Adenostoma fasciculatum H. & A.

Heteromeles arbutifolia M. Roem.

Rosa californica Cham. & Schlecht.

30. Rubiaceae:

Galium triflorum Michx.

31. Salicaceae:

Salix laevigata Bebb.

32. Scrophulariaceae:

Mimulus cardinalis Dougl. ex Benth.

Penstemon sp. Mitch.

33. Solanaceae:

Datura meteloides A. DC.

Nicotiana glauca Grah.

Solanum Xantii Gray

34. Typhaceae:

Typha sp. L.

35. Umbelliferae:

Conium maculatum L.

Foeniculum vulgare Mill.

36. Urticaceae:

Urtica holosericea Nutt.

37. Vitaceae:

Vitus californica Benth.

Appendix C. Species List Arranged by Plant Families - Walnut Study Area, Sulphur Mountain

1. Anacardiaceae:

   Rhus diversiloba T. & G.

2. Caprifoliaceae:

   Sambucus mexicana Presl.

   Symphoricarpos mollis Nutt. in T. & G.

3. Caryophyllaceae:

   Silene gallica L.

   Stellaria media (L.) Vill.

4. Compositae:

   Artemesia californica Less.

   Baccharis pilularis ssp. consanguinea (D.C.) C. B. Wolf

5. Cruciferae:

   Dentaria californica Nutt.

   Erysimum Cheiri (L.) Crantz.

6. Euphorbiaceae:

   Euphorbia Peplus L.

7. Fegaceae:

   Quercus agrifolia Nee.

8. Geraniaceae:

   Geranium molle L.

9. Gramineae:

   Avena fatua L.

   Elymus sp. L.

   Festuca sp. L.

10. Juglandaceae:

Juglans californica Wats.

J. californica X *J. regia* ex Burbank

11. Labiatae:

Marrubium vulgare L.

Stachys bullata Benth.

12. Leguminosae:

Lathyrus tingitanus L.

L. vestitus ssp. *puberulus* (White ex Greene) C. L. Hitchc.

13. Onagraceae:

Clarkia Xantiana Gray.

Zauschneria cana Greene

14. Portulacaceae:

Montia perfoliata (Donn) Howell.

15. Pteridaceae:

Adiantum Jordani C. Muell.

Pellaea mucronata (D.C. Eat.) D.C. Eat.

16. Rannunculaceae:

Ranunculus californicus Benth.

17. Rosaceae:

Heteromeles arbutifolia M. Roem.

Rubus ursinus Cham. & Schlecht.

18. Rubiaceae:

Galium triflorum Michx.

19. Saxifragaceae:

Lithophragma Cymbalaria T. & G.

Ribes speciosum Pursh.

20. Scrophulariaceae:

Castilleja affinis H. & A.

Penstemon cordifolius Benth.

21. Umbelliferae:

Osmorhiza brachypoda Torr.

Vegetation Classification and Mapping Program

The Vegetation Classification and Mapping Program (VegCAMP) develops and maintains California's expression of the National Vegetation Classification System. We implement its use through assessment and mapping projects in high-priority conservation and management areas, through training programs, and through working continuously on best management practices for field assessment, classification of vegetation data, fine-scale vegetation mapping, and archiving of vegetation data. Completing a state-wide vegetation map and classification in collaboration with other agencies and organizations is the current goal of the program.

Table 2: Field key to the defined vegetation associations of The Santa Monica Mountains and Simi Hills area, Ventura and Los Angeles Counties, California. 54

TREE OVERSTORY VEGETATION DESCRIPTIONS 94

Alnus rhombifolia-Platanus racemosa Woodland/Forest Association 94
Eucalyptus Woodland/Forest Alliance 98
Juglans californica/Annual Grass-Herb Woodland/Forest Association 101
Juglans californica/Artemisia californica/Leymus condensatus Woodland/Forest Association 104
Juglans californica/Ceanothus spinosus Woodland/Forest Association 107
Juglans californica/Heteromeles arbutifolia Woodland/Forest Association 110
Juglans californica/Malosma laurina Woodland/Forest Association 113

Platanus racemosa South Coast Intermittent Stream Woodland/Forest Association 116
Platanus racemosa/Annual Grass-Herb Woodland/Forest Association 119
Platanus racemosa-Quercus agrifolia South Coast Woodland/Forest Association 123
Platanus racemosa-Quercus agrifolia/Baccharis salicifolia/Artemisia douglasiana South Coast Woodland/Forest Association 126
Platanus racemosa-Quercus agrifolia-Salix lasiolepis Woodland/Forest Association 130
Quercus agrifolia South Coastal Woodland/Forest Association 134
Quercus agrifolia/Adenostoma fasciculatum Woodland/Forest Association .. 137
Quercus agrifolia/Annual Grass-Herb Woodland/Forest Association 140
Quercus agrifolia/Ceanothus spinosus Woodland/Forest Association 144
Quercus agrifolia/Heteromeles arbutifolia Woodland/Forest Association 147
Quercus agrifolia/Quercus berberidifolia Woodland/Forest Association 150
Quercus agrifolia/Salvia leucophylla-Artemisia californica Woodland/Forest Association 153
Quercus agrifolia/Toxicodendron diversilobum Woodland/Forest Association 156
Quercus agrifolia-Juglans californica Woodland/Forest Association 160
Quercus agrifolia-Salix lasiolepis Woodland/Forest Association 163
Quercus agrifolia-Umbellularia californica Woodland/Forest Association 166
Quercus agrifolia-Umbellularia californica/Ceanothus oliganthus Woodland/Forest Association 170
Quercus lobata/Annual Grass-Herb Woodland/Forest Association 174
Quercus lobata-Quercus agrifolia/Annual Grass-Herb Woodland/Forest Association 177
Quercus lobata-Salix lasiolepis Woodland/Forest Association 180
Salix laevigata-Salix lasiolepis Woodland/Forest Sub-alliance 184
Salix laevigata-Salix lasiolepis/Artemisia douglasiana-Rubus ursinus/Annual Grass-Herb Woodland/Forest Association 187
Salix laevigata-Salix lasiolepis/Baccharis salicifolia Woodland/Forest Association 191
Salix lasiolepis Woodland/Forest Alliance 194
Salix lasiolepis/Baccharis salicifolia Woodland/Forest Association 198
Salix lasiolepis/Malosma laurina Woodland/Forest Association 201
Schinus molle Woodland/Forest Alliance 204
Umbellularia californica/Ceanothus oliganthus Woodland/Forest Association 207
Umbellularia californica-Alnus rhombifolia Woodland/Forest (provisional) Association 210
Umbellularia californica-Juglans californica/Ceanothus spinosus Woodland/Forest Association 214
Umbellularia californica-Platanus racemosa Woodland/Forest Association .. 217

SHRUB OVERSTORY VEGETATION DESCRIPTIONS 220

Adenostoma fasciculatum-Ceanothus megacarpus Shrubland Association .. 223
Adenostoma fasciculatum-Eriogonum fasciculatum Shrubland Association . 226
Adenostoma fasciculatum-Malosma laurina Shrubland Association 229
Adenostoma fasciculatum-Malosma laurina-Eriodictyon crassifolium/ Annual Grass-Herb Shrubland Association 232
Adenostoma fasciculatum-Mimulus aurantiacus Shrubland Association 235
Adenostoma fasciculatum-Salvia leucophylla Shrubland Association 238
Adenostoma fasciculatum-Adenostoma sparsifolium-Ceanothus crassifolius Shrubland Association 241
Adenostoma fasciculatum-Arctostaphylos glandulosa Shrubland Association 244
Adenostoma fasciculatum-Arctostaphylos glauca Shrubland Association 247
Adenostoma fasciculatum-Ceanothus crassifolius-Malosma laurina Shrubland Association 250
Adenostoma fasciculatum-Ceanothus cuneatus-Salvia mellifera-Malosma laurina Shrubland Association 253
Adenostoma fasciculatum-Salvia mellifera Shrubland Association 256
Adenostoma fasciculatum-Salvia mellifera-Malosma laurina Shrubland Association 259
Adenostoma fasciculatum-Salvia mellifera-Rhus ovata Shrubland Association 262
Adenostoma sparsifolium Shrubland Alliance 265
Arctostaphylos glandulosa Shrubland Alliance 268
Arctostaphylos glauca Shrubland Alliance 271
Artemisia californica Shrubland Association 274
Artemisia californica/Leymus condensatus Shrubland Association 278
Artemisia californica-Eriogonum cinereum Shrubland Association 281
Artemisia californica-Mimulus aurantiacus Shrubland Association 284
Artemisia californica-Eriogonum fasciculatum/Annual Grass-Herb Shrubland Association 288
Artemisia californica-Eriogonum fasciculatum-Salvia leucophylla Shrubland Association 292
Artemisia californica-Eriogonum fasciculatum-Salvia mellifera Shrubland Association 295
Atriplex lentiformis Shrubland Alliance 298
Baccharis pilularis/Annual Grass-Herb Shrubland Association 301
Baccharis pilularis-Artemisia californica Shrubland Association 304
Baccharis salicifolia Riparian Shrubland Association 308
Ceanothus crassifolius Shrubland Association 311
Ceanothus crassifolius-Malosma laurina Shrubland Association 314
Ceanothus cuneatus-Quercus berberidifolia Shrubland Association 317
Ceanothus megacarpus Shrubland Association 320
Ceanothus megacarpus-Adenostoma fasciculatum Shrubland Association .. 324

Ceanothus megacarpus-Adenostoma sparsifolium Shrubland Association ..327
Ceanothus megacarpus-Cercocarpus betuloides Shrubland Association 330
Ceanothus megacarpus-Malosma laurina Shrubland Association 333
Ceanothus megacarpus-Salvia mellifera Shrubland Association 336
Ceanothus oliganthus Shrubland Association 339
Ceanothus oliganthus-Adenostoma sparsifolium Shrubland Association.....342

APPENDIX 1. Vegetation sampling protocols and field forms. 677

INTRODUCTION

The U.S. Geological Survey (USGS) and National Park Service (NPS) formed a partnership in 1994 to map the vegetation of the United States National Park system units using The Nature Conservancy's National Vegetation Classification, a standard for reporting vegetation information among federal agencies (Grossman et al. 1998). Goals of the projects include providing baseline ecological information to resource managers in the parks; putting the data into regional and national contexts; and providing opportunities for future inventory, monitoring, and research activities. Each park developing a vegetation map follows a standardized field sampling and vegetation classification protocol to document the various vegetation types found in that park. This information is used by photointerpreters to delineate polygons of vegetation communities, which are subsequently subjected to an accuracy assessment process (USGS 1994). The final products consist of a vegetation map, descriptions of each vegetation type, a key to each type, and all related data and metadata files (original field forms, plot database, accuracy assessment points, etc.). This report presents the work at the Santa Monica Mountains National Recreation Area (NRA) (park code: SAMO) and environs conducted from 2001 to 2005.

The Santa Monica Mountains in Context

The Santa Monica Mountains are not only the most accessible and largest piece of natural land adjacent to the western Los Angeles Basin but also play an important role in the panoply of vegetation in southern coastal California. Fire history, soil differences, a variety of moisture regimes, and topography all combine to create complex patterns of woodland, chaparral, coastal scrub, and grassland vegetation. The mountains are home to several locally common but regionally restricted species (such as *Ceanothus spinosus, C. megacarpus, Eriogonum cinereum,* and *Coreopsis gigantean*), each because of its high sociability and abundance defines its own suite of vegetation types. Other alliances defined by *Encelia californica, Salvia leucophylla, Juglans californica,* and *Rhus integrifolia* are widespread in southern coastal California but display a concentrated distribution and a broader variation of vegetation associations here than anywhere else.

The Santa Monica Mountains are the westernmost and lowest of the transverse ranges of southern California. They have small stands of high-elevation chaparral alliances such as *Quercus wislizeni* var. *frutescens* and *Arctostaphylos glandulosa,* remnants of a cooler and perhaps moister climate. However, they are tall enough to sustain a more extensive presence of some higher-elevation chaparral alliances such as *Ceanothus oliganthus* and *Adenostoma sparsiflora*.

They also contain the southernmost viable stands of *Quercus lobata* woodlands in California and among the largest remaining woodlands of *Juglans californica*.

The seaward bases of the mountains have Baja, California-like succulent coastal scrub including stands of *Opuntia littoralis, O. oricola,* and *O. prolifera* along with drought deciduous scrubs including *Salvia leucophylla, Artemisia californica,* and the largely insular *Coreopsis gigantea.* The core of the mountains includes thousands of acres and varied examples of *Ceanothus spinosus* and *C. megacarpus* alliances, both representing the center of their world distribution.

Riparian vegetation includes extensive woodlands of *Platanus racemosa, Salix lasiolepis,* and *S. laevigata,* which often interface with lower slope woodlands of *Quercus agrifolia, Juglans californica,* and *Umbellularia californica*. Further south, the latter two alliances diminish significantly, thus signifying the biogeographic role of the Santa Monica Mountains as crossroads between northern and southern California coastal vegetation.

Background and Standards

The U.S. National Vegetation Classification (USNVC) applied throughout this report was developed by NatureServe in partnership with the network of State Natural Heritage Programs (under the guidance of The Nature Conservancy). Additional support was provided by federal agencies and the Ecological Society of America. A first edition of the classification has been released that provides a thorough introduction to the classification, its structure, and the list of vegetation units known in the United States as of April 1997 (Grossman et al. 1998). Refinements to the classification have been occurring in the application process, leading to ongoing proposed revisions that are reviewed both locally and nationally. These refinements are best seen using the NatureServe Web site at http://www.natureserve.org/explorer/.

Vegetation mapping in national parks has been done under the auspices of the NPS Inventory and Monitoring Program, in close cooperation with the USGS Biological Resources Division. The mapping is done in accordance with standards established by the Federal Geographic Data Committee (FGDC) for vegetation mapping on federal lands. The FGDC Web site (http://www.fgdc.gov/standards/standards_publications/index_html) explains the development of the classification standards currently used for mapping and classifying vegetation in national park. The USGS Biological Resources Division—NPS Vegetation Mapping project Web site (http://biology.usgs.gov/npsveg/standards.html) has additional information on vegetation mapping in national parks.

The development of a vegetation classification and concomitant map is a complex project. Not all vegetation types are equally mappable at a certain scale. Coordination between the vegetation classification team and the aerial photointerpreters is needed to resolve the best way to map the types, whether directly at the finest association level, at the higher-classification levels (such as at the alliance), or as a mosaic or complex. Thus, not all types described in this report are necessarily mapped directly. A separate report documents the link between the mapping and the field-based vegetation classification (AIS 2005, in preparation).

Initially in the mid 1990s, several California parks were chosen by USGS-NPS to be part of the prototype phase of the program representing different regions, environmental conditions, and vegetation types. The initial goal of the prototype phase is to "develop, test, refine, and finalize the standards and protocols" to be used during the production phase of the project. The program includes the development of a standardized vegetation classification system for each park and the establishment of photointerpretation, field sampling, and accuracy assessment procedures. Following initial projects of classification and mapping of Point Reyes National Seashore (2003), Golden Gate National Recreation Area (2003), Yosemite National Park (2003), Joshua Tree National Park (2005), and Sequoia National Park (2004), the decision to develop a map was made by SAMO staff based on (1) a desire to maintain consistency with the work done at these other parks, (2) the quality of the work performed at these parks, and (3) sufficient development and testing (proven application) of protocols and procedures.

SAMO is situated in an urban-wildland interface in the south coastal portion of Southern California. As such, it is the first national park unit to be mapped and classified in California where fire management and fuels prediction attain such a critical level. Funding for this project came largely from the NPS Fire Management Program. Results from this report and the associated vegetation map are expected to inform fire management decisions for SAMO and the adjacent areas. Because ownership is complex in the Santa Monica Mountains, the park determined that a complete classification and map of the environs of the entire area were necessary to properly deal with integrated management issues.

The area in this study covers approximately 350,000 acres and stretches from Point Mugu and the associated Mugu Lagoon tidal marsh on the west to Griffith Park in the city of Los Angeles to the east. It reaches from Point Dume and Malibu on the south to the Simi Hills and Montcleff Ridge on the north (figure 1).

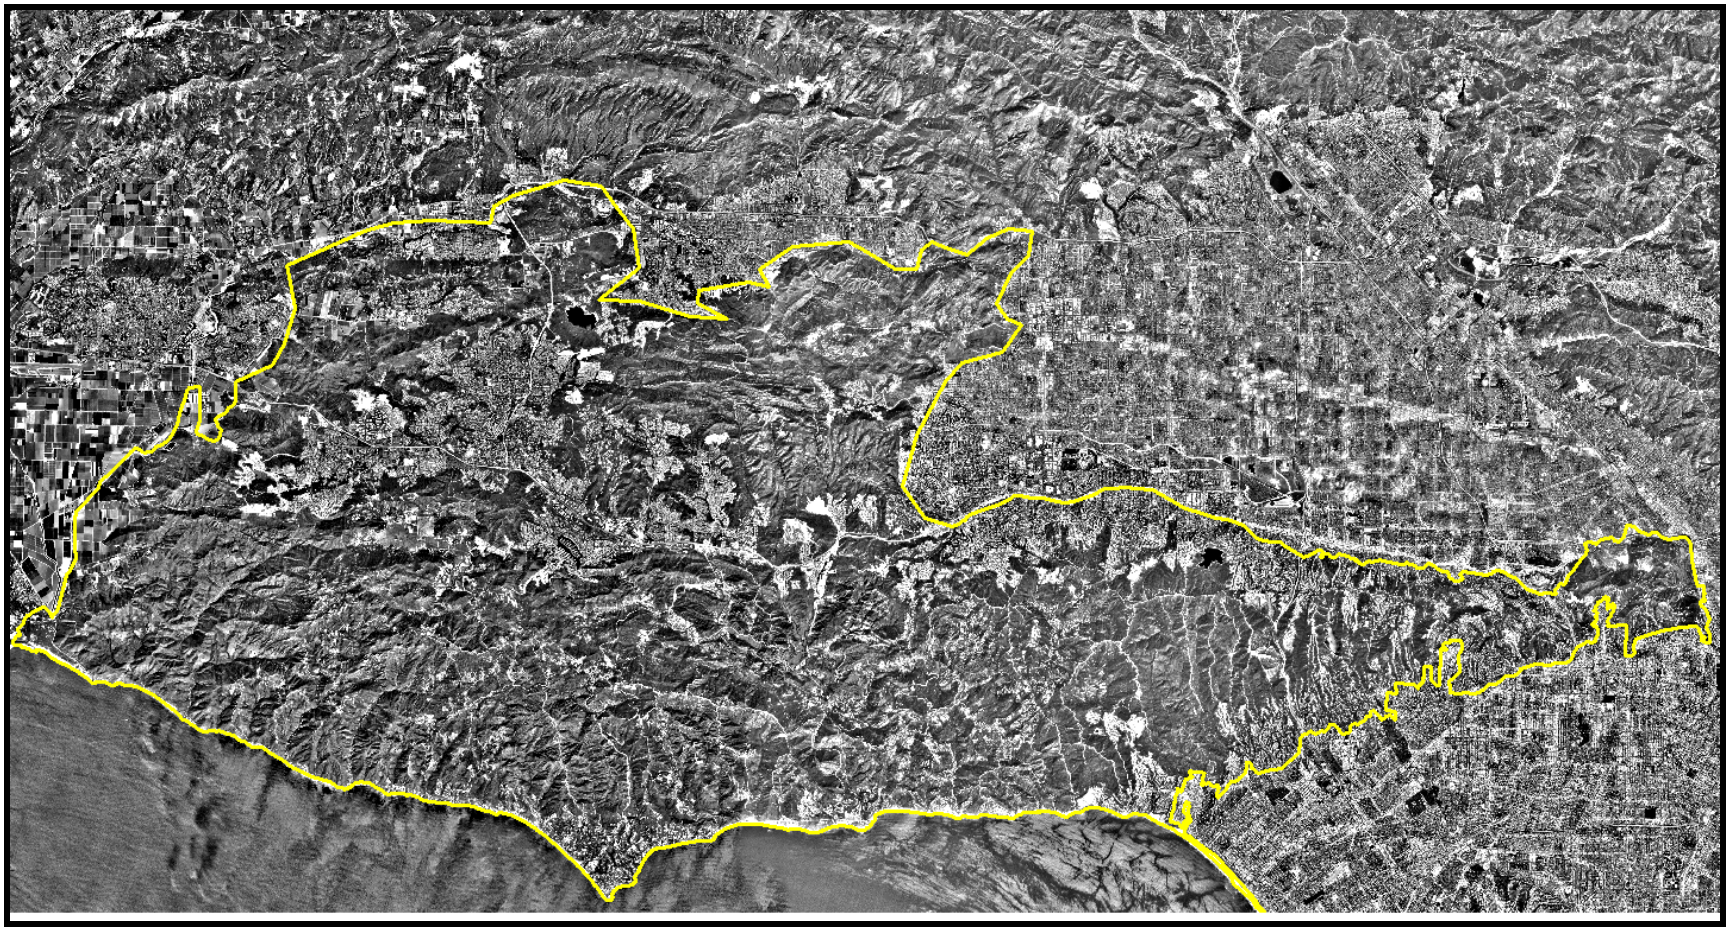

Figure 1: Shown is a SPOT 2002 satellite image of Santa Monica Mountains with the study area boundary in yellow. Note the large expanse of urban to the northeast and southeast and mix of agriculture and urban to the west and north. This image is best viewed at 300–400 percent of current scale.

The Santa Monica Mountains NRA extends 46 miles from the Hollywood Bowl to Point Mugu in Ventura County. It also runs along the coastline from the Santa Monica Pier west past Malibu. The U.S. Congress created the Santa Monica Mountains National Recreation Area in 1978 and charged NPS with supporting a shared management of the park. NPS, State Parks, and the Santa Monica Mountains Conservancy jointly administer the public parklands of the area. In the immediate vicinity of the park live approximately 17 million people.

With respect to landowners, the California State Parks is the largest landowner within the recreation area with 42,000 acres. However, approximately half the land in the recreation area is privately owned and more than 70 government entities have jurisdiction within the boundary. The city of Malibu is entirely within the park's boundary. The recreation area is approximately154,000 acres. However, in an effort to develop an ecologically realistic and managerially usefull map, more than double that area has been included in this study.

This report outlines and describes the project timeline, vegetation classification methodologies, sampling criteria, and data analysis procedures implemented in creating the final vegetation layer for SAMO. It describes the result of this classification process in terms of a formal classification list, key, and description of all vegetation types identified during this process.

Funds for this project were provided by the National Park Service Fire Management Program, National Park Service Inventory and Monitoring Program, Mountains Recreation and Conservation Authority (Santa Monica Mountains Conservancy), United States Army Corps of Engineers, and the Resource Management Agency of Ventura County. Initial funding for the project was received in 2001 and a contract was entered into with ESRI to develop a vegetation classification and map. Primary responsibility for development of the classification was assigned to Todd Keeler-Wolf (California Department of Fish and Game [CDFG], California Heritage Program senior vegetation ecologist) and Julie Evens (California Native Plant Society [CNPS] vegetation ecologist). John Tiszler served as the NPS contracting officer's technical representative and project manager. NPS assumed responsibility for field data collection, vegetation database management, and statistical analyses.

As the contract for the classification and portion of the project was developed, NPS worked with ESRI as the principal contractor and ESRI subcontracted with the California Native Plant Society via the California Heritage Program ecologist (housed at California Department of Fish and Game), representing NatureServe in California. ESRI also subcontracted with Aerial Information Systems of

Redlands, California, to produce the map driven by the classification developed by CNPS and CDFG.

The primary motivation for this project was to produce a new vegetation classification and map that meets NPS and USNVC standards and to provide the information base necessary to develop effective fire hazard management strategies while fully protecting natural resource values. In addition, we anticipate the classification and map will have many uses for the numerous public planning and land conservation agencies with jurisdiction in the Santa Monica Mountains and Simi Hills. The classification and map will provide a highly detailed spatial assessment of native vegetation and, as such, will be a valuable planning tool where habitat connectivity, sensitive vegetation types, and protection of designated Ecologically Significant Habitat Areas are of concern. The capacity to make local vegetation management and other land-use decisions will be greatly improved.

The principal needs for this mapping project were the following:

- Implement a GIS-based, gradient-directed transect (GRADSECT) approach for sampling.

- Integrate the vegetation sampling process with the photointerpretation process so a seamless, mutually beneficial feedback loop would develop, with the field crews providing information to the mapping team at the same time mappers would be supporting decisions by field crews about where and what to sample.

- Integrate any existing or ongoing vegetation data with the necessary field data to be collected during this project into a unified vegetation classification that would be used for the final vegetation description and vegetation mapping products.

- Work with the unique characteristics of a chaparral and coastal sage scrub and develop the best methods for detailed classification and mapping of this vegetation.

- Work within a complex urban-wildland area surrounded on all sides by major population centers to develop a detailed classification and map that would address many key issues of urban-wildland vegetation management.

The scientific purpose of developing the classification for the area to be mapped was to integrate a large amount of new information into California's vegetation

classification and USNVC. This report provides the basis to achieve that goal. By standardizing the reporting structure of each new classification unit, NatureServe will be able to integrate this information into the national vegetation classification.

This project was the first effort to extensively employ the CNPS Rapid Assessment Vegetation Sampling Protocol, as seen through the following link: http://www.cnps.org/programs/vegetation/protocol.htm. This technique was selected in addition to the standard accuracy assessment sampling protocol and the relevé sampling protocol used regularly by the National Park vegetation program because of its ability to represent large numbers of vegetation stands quickly, thus increasing the sample size and range of sampling locations for all types of vegetation. The rapid assessment protocol was expected to be an efficient way to inventory many dense and difficult to penetrate stands of chaparral and coastal scrub, where the species indicative of particular ecological settings are primarily in the shrub layer and not in the understory herb and grass layer. It was used extensively in virtually all types of vegetation in this project except for the species-rich riparian, oak, and other hardwood woodlands; coastal sage scrub; and grasslands in which releves were used to augment the samples. The diversity of species and the more significant variation of understory species in these situations require a full sample of all species present to more accurately classify and understand the variations in these types of vegetation. For a thorough explanation of the protocol see appendix 1.

NPS Field Crew and Supporting Staff

Five crew members were hired or reassigned by the park in the summer of 2003. They were James Anderson, Rachel Buchwalter, Julie Christian, Charles Hohn, and Mike McGraw. Park staff Brendan Clark and Tarja Sagar also assisted with surveys on an intermittent basis. Christian served as crew leader and was responsible for scheduling and assignment of all field and laboratory activities. Buchwalter left the project in 2003, and the crew continued as four members with intermittent staff support until field sampling was completed. In total, more than 6,700 vegetation stands were visited to obtain information necessary for classification and photointerpreter training.

Christian was responsible for management of the vegetation databases including data quality assurance and control. She maintained and updated the metadata that recorded changes to the evolving classification. She also organized data into formats suitable for statistical analysis. Park GIS analyst Robert Taylor performed the statistical analyses with support from Christian.

Timeline

2001

From June 18–20, an initial reconnaissance of the SAMO area was conducted by the CDFG state ecologist and the principal ecologist of the park. An initial classification list was developed following that meeting. Aerial photography was acquired in July 2001.

On November 8, a meeting was held at SAMO to bring together the project team members from the NatureServe, ESRI, AIS, and CDFG as well as other outside participants knowledgeable in the vegetation of the Santa Monica Mountains. This meeting focused primarily on discussing the Vegetation Inventory and Mapping Program, existing park data, logistics, and park-specific issues. A general overview of the project and processes involved was outlined.

2002

In February, the CDFG state ecologist met with the SAMO GIS staff to begin developing a gradient-directed approach to identifying initial sampling and mapping areas in the park. This work was continued through mid-March by the SAMO GIS staff.

Beginning in March, reconnaissance trips including the photointerpreters from AIS, park ecologists, and CDFG state ecologist began. These were two- to three-day trips that were intended to augment the preliminary vegetation classification and familiarize the air photointerpreters with the vegetation of the region. Each trip focused on a separate portion of the study area.

The second reconnaissance trip was conducted from April 22–24, followed by the subsequent revision of the preliminary classification. The CNPS vegetation ecologist joined the team of AIS, CDFG state ecologist, and the SAMO field team and associated park ecologists. The third reconnaissance trip was conducted in June and consisted of the same members.

The vegetation sampling field crew was hired in July 2002 and served through completion of the vegetation classification in January 2005. Training of crews in the use of the rapid assessment sampling protocol was conducted in July by the CDFG state ecologist and assistant ecologist, Diana Hickson.

The fourth reconnaissance trip was conducted in early September, followed by subsequent revision of the preliminary classification. Training for releve and accuracy assessment sampling protocols was conducted in early December.

2003

In March, the fifth reconnaissance trip was conducted, followed by subsequent revision of the preliminary classification.

In July, the first intensive analysis of 11 months (1,807 individual samples) of rapid assessment plots was conducted. Data was prepared by Julie Christian, and initial TWINSPAN and cluster analyses were run by Robert Taylor with assistance from Julie Evens and Todd Keeler-Wolf. Three days of intensive analysis were conducted by this group with assistance in local interpretation by all members of the field crew. Following this classification, a meeting with the photointerpreters was held to translate the vegetation classification to an updated mapping classification.

In August, a revised classification list was produced using the existing and newly adjusted recommended sample sizes of vegetation types to fully represent the vegetation categories established and assumed to occur.

In the last five months of 2003 and the first few months of 2004, vegetation data collection emphasized more accuracy assessment and releve samples.

2004

In June, an intensive analysis of the full dataset of 3,790 rapid assessments, accuracy assessments, and 122 releves was undertaken in a meeting between CDFG, CNPS, and SAMO ecologists. Prior to the meeting, Taylor and Christian undertook the data preparation and initial cluster analysis runs for the rapid assessment data, and CNPS ecologists Klein and Evens undertook the analysis for the relevé data. This analysis meeting was followed by several more days of intensive analysis by CDFG and CNPS to produce the full classification. In November and December, this classification was simplified and some initial types were reduced to synonymy or subcategories of associations called phases, with consulatation with Gwen Kittel, NatureServe's regional ecologist.

2005

In January, the classification was finalized, and description format was decided upon by all of the collaborators. Descriptions were begun by CNPS with assistance from NatureServe (and Nature Conservancy subcontractor) and CDFG. In April, all initial description data was summarized.

In June, all full descriptions were written and submitted for review, and in July to December 2005, the report was reviewed by SAMO staff and finalized January 2006.

METHODS

Gradient-Directed Sample Allocation

To strategically assess the vegetation of the area, an interactive process was developed between the SAMO field sampling team and the aerial photointerpreters at AIS. This revolved around the selection of individual subareas centered on 180 aerial photos at 1:12,000 scale from the study area. Each of these subareas was selected through a GIS analysis of the environmental variables thought to drive the distribution of the principal vegetation types in the area. Denise Kamradt and Robert Taylor of SAMO and Todd Keeler-Wolf of CDFG met and developed the criteria based on a combination of geologic, precipitation, temperature, and solar insolation (based on slope and aspect) information available in the SAMO GIS files. Specifically the process included three main components:

1. Classifiying a March solar radiation layer into three classes. A 900-meter grid was created over the study area with all grid cells that did not contain all three solar radiation classes removed. This is the radiation_variety grid.

2. Classifiying and combining layers for (a) fire history, (b) geology, (c) average annual precipitation, and (d) average maximum July temperature.

   The resulting layer was a raster with a 30-meter cell that was modified in the following way:

   - Masked out cells that were not on public land
   - Masked out cells that fell within the larger 900-meter radiation_variety, where not all three solar radiation categories were represented

3. From the resulting layer, a list of all unique combinations of the four input layers was developed and modified in the following way:

   - Masked out cells for unique combinations with fewer than 900 cells each
   - Converted grid to point layer

The result is the GRADSECT layer. From the GRADSECT layer, one point was randomly selected for each unique combination of the four input layers.The result was a table of 93 "GRADSECT" points. These points became the core of initial sample selection for the field crew and also were expanded upon for further sampling later in the field seasons of 2002 and 2003. Broader interpretation of the environmental variables developed from the GRADSECT analysis resulted in the development of an ecological subregionalization of the study area.

The first cut of climate and geology produced a total of seven general subregions (figure 2). These regions are briefly described below. The photointerpretation team selected 180 aerial photographs that were considered representative of each of these subregions. For each of 180 aerial photos selected as the first phase of development, a number of possible sampling locations in parklands were selected representing the range of environmental conditions found in the analysis.

Figure 2. Ecological Regions Identified for Vegetation Assessment

The following descriptions serve as brief characterizations of each of these seven regions.

Region 1

Title: Western Fog Zone (CSS on Volcanics)
General Location: Far West End of Range as Hits Oxnard Plain
Ave-Hi/Low Summer Temp: (Camarillo) 75/55
Ave-Hi/Low Winter Temp: 65/45, Records Below 32
Fog Description: Often Foggy, Possible Year-Round
Precipitation: 10–15", Lower than Region 2
Geology: Igneous > Quaternary >> Low Sedimentary
Soil: Incomplete, Coastal Sage > Igneous Chaparral
Elevation Range: 0–1800'

Region 2

Title: Immediate Coast (CSS)
General Location: East-West Band along Immediate Coast, South-Facing Slope of Mountains
Ave-Hi/Low Summer Temp: (Malibu) 70/60
Ave-Hi/Low Winter Temp: 65/50, No Record Lows Below 32
Fog Description: Often Foggy, Possible Year-Round
Precipitation: 15–18", Higher than Region 1
Geology: Sedimentary >> Quaternary ~ Igneous
Soil: Coastal Sage > Sedimentary Chaparral > Coastal Terrace > Sandstone Chamise/Chaparral > Igneous Chaparral
Elevation Range: 0–1500'

Region 3

Title: Upper Elevation Santa Monica Mountains (Chaparral)
General Location: South-Facing Slope of Mountains, Mid to Top
Ave-Hi/Low Summer Temp:
Ave-Hi/Low Winter Temp:
Fog Description: Mostly Spring
Precipitation: 18–23", 28" at Highest Elevations
Geology: Sedimentary > Igneous >> Quaternary
Soil: Sedimentary Chaparral ~ Sandstone Chamise/Chaparral ~ Igneous Chaparral
Elevation Range: 1000–3100'

Region 4

Title: Lower Elevation Inland Santa Monica Mountains (Chaparral)
General Location: North-Facing Slope of Mountains, Mid-Lower
Ave-Hi/Low Summer Temp: (Newbury Park) 80/50, Record Highs in 100s
Ave-Hi/Low Winter Temp: 70/40, Record Lows in Lower 20s
Fog Description: Usually in Spring
Precipitation: 18"
Geology: Igneous > Sedimentary > Quaternary
Soil: Incomplete, Igneous Chaparral > Marine Sedimentary >> Coastal Terrace
Elevation Range: 1000–2000'

Region 5

Title: Inland Dry (CSS)
General Location: South-Facing Slope of Simi Hills, Lower Slope
Ave-Hi/Low Summer Temp: (Thousand Oaks + Moorpark) 90/55, Record Highs in 110s
Ave-Hi/Low Winter Temp: 70/40, Record Lows in 20s (Moorpark is a bit more mild.)
Fog Description: Spring Only
Precipitation: 13–18"
Geology: Sedimentary > Quaternary > Igneous
Soil: Incomplete, Marine Sedimentary
Elevation Range: 900–1800'

Region 6

Title: Simi Hills Inland (Chaparral)
General Location: Simi Hills, Mid to Top Slope
Ave-Hi/Low Summer Temp:
Ave-Hi/Low Winter Temp:
Fog Description: Spring, Early Summer
Precipitation: 18"
Geology: Almost Exclusively Sedimentary >>> Igneous = Quaternary
Soil: Incomplete, Marine Sedimentary
Elevation Range: 900–2400'

Region7

Title: Eastern Urban (Chaparral)
General Location: Far East, Urban
Ave-Hi/Low Summer Temp: (Beverly Hills) 75/60, Record Highs in 100s

Ave-Hi/Low Winter Temp: 65/50, Record Lows in Mid 30s
Fog Description: Unknown
Precipitation: 18–22"
Geology: Sedimentary > Igneous > Metamorphic >> Quaternary
Soil: Incomplete, Sedimentary Chaparral/Urban Land, Urban Land
Elevation Range: 400–1750'

Sources used to define these regions include the following:

Precipitation

This layer represents lines of equal rainfall (isohyets) based on long-term mean annual precipitation data compiled from USGS, California Department of Water Resources, and California Division of Mines map and information sources. Source maps are based primarily on U.S. Weather Service (USWS) data for approximately 800 precipitation stations. In the Los Angeles and San Francisco Bay areas, the USWS data has been supplemented by county and local agency precipitation data. The data was collected over a 60-year period (1900-1960). Minimum mapping unit is 1,000+ acres. The isohyetal contour intervals differ because of the degree of variation of annual precipitation with horizontal distance.

Geology

Existing USGS digital ArcInfo coverages were downloaded from the Southern California Aerial Mapping Project (SCAMP) subheading on the Western Region Digital Geologic home page (http://geology.wr.usgs.gov/wgmt/scamp/la/laquad.html) and imported into ArcInfo. Each quadrangle on the SCAMP page has separate digital data layers available describing the bedrock and superficial geology, structural geology, and paleontological resources of the area. Only bedrock and superficial geologic information was acquired and processed by the National Park Service.

Soil

1967, USDA Soil Conservation Service, "Soils of the Malibu Area, California"

Temperature
www.weather.com

Within each of these seven regions, a representative proportion of the total 180 photos was selected based on the aerial extent and ecological diversity of each

subregion. Within each of the areas covered by these individual air photos, a random selection of points was made that focused on the variety of solar insolation settings within them. These points were given to the field crews as a set of possible choices to visit for individual field sampling. All selected sample locations were restricted to parkland.

Field Sampling

A preliminary classification was developed (see Existing Literature Review section below) following the reconnaissance trips and given to the Park vegetation sampling crew to assist them in identifying individual stands for rapid assessment or releve sampling. This classification list was used in conjunction with the ongoing photointerpretation work by the photointerpretation contractor, Aerial Information Systems. The interplay between the photointerpreters and the field crew included requests by AIS for field identification of representative photo signatures. These were accomplished in either rapid assessment or less complete reconnaissance-level field checks, where the main species and the preliminary classification name of individual stands were delivered to AIS. The data sharing between the field crews and the photointerpreters was one of the key points in this vegetation mapping effort. Compared to earlier National Park mapping efforts in California, it attained much higher levels of refinement and cooperation.

Field crews relied on the photointerpreters for preliminary delineations to assist them in targeting stands to be sampled. Thus, as individual aerial photos were delineated and labeled, field crews would focus on a particular aerial photo to field check, dividing their efforts between rapid assessment, releve, reconnaissance and, as the process ramped-up in the later phases of fieldwork, more accuracy assessment fieldwork. The latter sampling was done and then withheld from the photointerpreters until the completion of their work to apply a nonbiased way to test the accuracy of their work. More detailed descriptions of this process may be found in the final report by the photointerpreters.

Vegetation Sampling and Classification

Existing Literature Review

Beginning in early April 2003, information from a California vegetation classification (Sawyer and Keeler-Wolf 1995), recent classifications for adjacent areas of southern California (CDFG 1998, Borchert et al. 2004, then in draft form, Gordon and White 1994), and other existing literature were reviewed to obtain a current view of the local vegetation with respect to the National Vegetation Classification (Grossman et al. 1998). This information was compiled into a

preliminary, floristic classification of vegetation at the alliance and association levels. Further, the initial reconnaissance of the study area supplemented this classification. The initial inventory included nearly 100 associations and suggested about 150 alliances in the mapping area.

Data Analysis Process

The sample dataset used for the classification included 3,790 vegetation rapid assessments, which were completed year-round from July 2002 to April 2004, and 122 releve samples, which were completed in the phenologically active periods of spring and summer from February to June 2003. The very large number of samples collected for this project far exceeded any previous study for a given National Park unit. Thus, special techniques were employed to analyze the data. This included an intermediate analysis that informed and refocused the final phase of data collection.

In June 2003, following the first full season of data collection, 1,807 rapid assessment samples were analyzed. This involved three intensive days of progressive fragmentation of cluster analysis and individual plot-by-plot inspection of the results. In addition to Julie Evens and Todd Keeler-Wolf, data analysis was assisted and or performed by Robert Taylor of SAMO, who initially ran the data through TWINSPAN and cluster analysis, and Julie Christian, who performed queries in MS Access to summarize the data and facilitate its interpretation. The 1,807 samples were broken into seven major groups based on their broad relationships within cluster analysis. Each of these major groups was further analyzed, and preliminary association names were revised or substantiated for many of these groups. Following this analysis, it was also possible to review the entire preliminary classification and determine how many samples had been collected for each of the types, and conversely, how many more samples needed to be collected for remaining types not yet adequately sampled.

One year later, more than twice as many samples had been collected by the field crews. Another classification marathon for one week was set up, where the principal data analysis personnel reconvened to analyze approximately 3,915 vegetation samples. In addition to Evens and Keeler-Wolf, Anne Klein, CNPS vegetation ecologist, was employed to assist in the analysis. A similar process was conducted including individual analysis of each plot after they had been divided into progressively smaller and smaller groups based on cluster analysis. A database was built by Christian specifically for tracking the classification results. In this session, approximately 90 percent of the samples were assigned to vegetation types defined by their relationships and similarities.

Following this meeting, another meeting to refine the classification and define the classification units in terms of mapping units for AIS was held at the AIS office in Redlands. The translation of vegetation units to mappable units was largely accomplished. However, additional refinement was needed to finalize the classification.

Keeler-Wolf, Klein, and Evens (the classification team) continued to refine the classification in the fall of 2004. They refined the classification and adjusted some of the finer cluster units of the analysis, proposing that some be aggregated into larger units instead of remaining individual associations. Several detailed meetings of the SAMO ecologists and the CNPS and CDFG ecologists ensued, also involving the regional NatureServe ecologists. In December 2004, a final classification was agreed upon enabling the formal description writing and key development associated with this report.

Cluster Analyses for Vegetation Classification

Following the 2002–2003 sampling effort by the field staff, the rapid assessment and releve data were statistically analyzed. The classification team worked with Robert Taylor and Julie Christian from the SAMO team to classify the data. The analysis was undertaken using the PC-ORD software suite of classification and ordination tools (McCune and Mefford 1997). PC-ORD performs multivariate analyses to place vegetation plot samples into a formalized classification of community types. Using programs such as TWINSPAN (Hill 1979), cluster analysis, and ordination (McCune and Mefford 1997), groups are defined by similarities in species composition and abundance. Since plant community datasets are inherently complex and more than one environmental axis determines the heterogeneity in plant patterns, a hierarchical agglomerative cluster analysis technique was employed with Sorenson distance and flexible beta linkage method at -0.25 (McCune and Grace 2002). The cluster analysis technique was based on abundance (cover) values converted to seven different classes using the following modified Braun-Blanquet (1932/1951) cover categories: 1 = < 1%, 2 = 1–5%, 3 = > 5–15%, 4 = > 15–25%, 5 = > 25–50%, 6 = > 50–75%, 7 = > 75%. The majority of the species values fell within the first four cover classes. Prior to these analyses, data was screened for outliers (extreme values of sampled stands or species), and these outliers were removed to reduce heterogeneity and increase normality in the dataset. Samples that were more than three standard deviations away from the mean were removed using outlier analysis in PC-ORD, and species that were in fewer than three samples were removed.

Because of the size and heterogeneity of the initial dataset, a first-order cluster analysis was used to partition the dataset into more manageable subsets. Thus, the main dataset was broken into distinct, smaller subsets of around 100–200 samples, and these smaller subsets were then individually analyzed by 2–3 teams of ecologists. Subsets of individual smaller cluster groupings usually included distinctly different vegetation types or habitats. A cluster analysis was run separately for the releve data because the species data was collected differently for the releve than for the rapid assessment method (i.e., data on all species found in defined plots for relevés as compared to data on the 10–20 main species found in stands for the other assessments).

After the cluster analyses, Indicator Species Analysis (ISA) was employed to decide objectively what group level(s) to "cut" from the dendrogram and explicitly interpret the groups. Further, ISA was used to designate species that indicate the different groups. ISA produced indicator values for each species in each of the groups within the dendrogram, and these species were tested for statistical significance using a Monte Carlo technique (Dufrene and Legendre 1997). In this case, indicator species with the highest values are the ones that show the highest fidelity for a particular cluster grouping. To attain a high-indicator value, they may be strongly dominant in a particular group or they may be just present consistently in low cover in a group. In general, species with low-indicator values are found commonly in multiple groups and are restricted to none.

For the rapid assessment and accuracy assessment dataset, ISA was repeated at group levels 100 and 250. Group level 100 represents a more generalized view (e.g., indicating only 100 groupings for all of the samples) while group level 250 is a more detailed view of the way all samples are arranged into 250 clusters of related stands. These analyses were evaluated to the total number of significant indicator species (p-value ≤ 0.5) within each group level and the mean p-value for all species. The group level that had the highest number of significant indicators and lowest overall mean p-value was selected for the final evaluations of the community classification (McCune and Grace 2002). At this grouping level, plant community names within floristic classes were applied to the samples of the different groups.

Naming conventions followed the floristic units of "associations," as defined by the National Vegetation Classification System (Grossman et al. 1998) and the California Native Plant Society (Sawyer and Keeler-Wolf 1995). An association is defined by a group of samples that have similar dominant and characteristic species in the overstory and other important and indicator species, whereby these species are distinctive for a particular environmental setting. Further, significant indicator species were drawn from the analysis and applied to the associations. A set of similar associations are grouped hierarchically to the next

level in the classification, the alliance defined as the basic, generic unit of floristic classification, usually by the dominant and/or characteristic plant species in the upper layer of vegetation. For example, different types of coast live oak woodland are classified to the association level depending on the characteristic overstory and understory species (e.g., Coast live oak/Chamise as opposed to Coast live oak/Scrub oak), while there is a coast live oak alliance based on the characteristic presence of coast live oak in the overstory.

The environmental field data collected on rapid assessment surveys is basic and tends to focus on general "hard" variables such as elevation, slope, aspect, soil texture, geology, and so forth (see the protocol in appendix 1).

Associations are usually differentiated by environmental factors as well as floristic characteristics. In vegetation, the arrangement of certain groups of species defining a category of vegetation correlates with a particular set of ecological situations, which may include "hard" or specific climatic and other environmental differences related to temperature, moisture, or soil nutrition; however, it may also imply more vague ecological characteristics such as modes, frequency, and intensity of disturbance. The environmental field data collected on rapid assessment and releve surveys is basic and tends to focus on general "hard" variables such as elevation, slope, aspect, soil texture, geology, and so forth (see the protocols in appendix 1). As definitions were developed, the data analysis team used the correlates to ascertain environmental variables, or lack thereof, to help determine whether or not a particular cluster grouping should be ranked as an association.

These environmental correlates were summarized following the species cluster analysis and are reported for each of the final definitions in this report. As many of the vegetation types defined in this report related to the "softer" variables that may be correlated with successional history following fire or other disturbance, it was difficult to draw specific, strong environmental correlations with many of the types. However, anecdotal comments in the descriptions focus on these when appropriate In cases where there was a group of vegetation samples that appeared somewhat floristically distinct but shared the same environmental characteristics with a larger group of samples, the term "phase" was used. A phase is an informal unit of classification that accommodates local floristic variation that tends to not have obvious correlations with certain environmental conditions, and it is best considered a part of a more definitive association. It probably results from very localized variation in the climate or site history, resulting from local relief, soil texture, geology, fire history, and so forth.

Each sample was revisited within the context of the cluster to which it had been assigned to quantitatively define membership rules for each association. The

membership rules were defined by species constancy, indicator species, and species cover values. Upon revisiting each sample, a few samples were found to be misclassified in earlier fusions of the cluster analysis, and these samples were reclassified based on the membership rules. The set of data collected throughout the study area was used as the principal means for defining the association composition and membership rules; however, existing classifications and floras were consulted to locate analogous/similar classifications or descriptions of vegetation. A summary of the analysis process is provided in the following steps.

1. Screen all sample-by-species data for outliers. Samples (each releve or rapid assessment was considered a "sample") that were more than three standard deviations away from the mean were removed, and species that were in fewer than three samples were removed.

2. Run presence-absence cluster analysis to determine general arrangement of samples.

3. Run cover category cluster analysis to display a more specific arrangement of samples based on species presence and abundance.

4. Run Indicator Species Analysis at each of the successive group levels in the cluster analysis output from two groups up to the maximum number of groups (all groups have at least 2 samples).

5. Settle on the final representative grouping level of each cluster analysis to use in the preliminary labeling.

6. Preliminarily label alliance and association for each of the samples and denote indicator species from the Indicator Species Analysis.

7. Develop decision rules for each association and alliance based on most conservative group membership possibilities based on review of species cover on a sample-by-sample basis.

8. Relabel final alliance for each sample and arrange in table of database.

9. Use decision rules developed in the new data to assign alliance and association names to all analyzed data and all outlier samples removed from the dataset.

Some rare vegetation types were underrepresented in the sampling effort. They were often the only representatives of rare alliances known from areas within the

study boundaries, or they were the only representatives of alliances that occur in other areas beyond the study boundaries in California. In addition, it was not possible to survey the full spectrum of vegetation because the study area had mixed ownership and accessibility. For these reasons, adequate data may not be available in this report for all vegetation types. However, any relatively unique samples are considered important and are described separately in the results. In some cases, they represent unusual species groupings not described but were viewed as affording perspective into unusual vegetation types that deserve additional sampling. These types are either described at a more generic alliance/habitat level or as unique stands.

Classification and Key

The classification and key were produced to identify all vegetation types detected in the fieldwork for this project. They are based on the standard floristic hierarchy of the U.S. National Vegetation Classification as supported by NatureServe (see www.natureserve.org or NatureServe 2004). They are based on species composition, abundance, and habitat/environment.

The key provides general choices and information on the physiognomy of the vegetation and the different environments based on wetland/upland position. This approach in the key was chosen to (1) reduce the length and redundancy that is common in dichotomous keys and (2) be a guide that can be easily used by nonbotanists/plant ecologists. The vegetation key can be used as a guide to the descriptions of vegetation within this report. It is written from two perspectives: (1) a field team attempting to identify vegetation and (2) an office team attempting to place field samples into the proper category. Thus, heavy reliance is placed on correct identification of characteristic plant species and of estimation of cover of these species.

The key is first broken into major units based on dominant plant life-form: trees, shrubs, and herbs. Within these groups, the key is further divided by coniferous/ broadleaf evergreen, chaparral/soft-leaved shrubs, wetland/upland distinctions, graminoid/forb distinctions, and so forth. The key and descriptions hopefully will afford further refinement to the understanding of the Santa Monica Mountains area and surrounding regions from the standpoint of both classification and mapping.

Philosophy of Vegetation Classification in This Report

The developing philosophy of vegetation classification in California has benefited a large number of recent classification projects centered in southern coastal California (DeSimone and Burk 1992, Gordon and White 1994, White et al. 1994,

Borchert et al. 2004, Evens and San 2005, Klein and Evens 2005). These, in conjunction with a growing understanding of statewide vegetation, have enabled the classification of the vegetation in the current project to proceed within a broader and better framework than would have been possible as little as five years ago. The natural development of most taxonomies, whether they be of species or vegetation, work their way through what can be called an expansive phase and then a synthetic phase. The first is characterized by the proliferation of many taxa based on local description without the benefit of broad comparison of related types. The second is based on a retrospective and broader view of more studies where related taxa can be compared and often shown to be related, thus ultimately synonymized. This latter phase has begun to take place in much of California, especially with the preparation of the second edition of the *Manual of California Vegetation* (Sawyer et al. 2006 MS).

For example, chaparral alliances defined in previous studies included several mixed species types including *Eriogonum fasciculatum-Encelia farinosa* (Gordon and White 1994)*, Ceanothus megacarpus-Cercocarpus betuloides* (Borchert et al. 2004), and *Ceanothus megacarpus-Rhamnus ilicifolia* (Borchert et al. 2004). These were named by the characteristic codominance of shrub species and were thought initially to represent fundamentally different entities than stands of vegetation dominated singly by individual species, for example, *Encelia farinosa* (without significant cover of *Eriogonum fasciculatum*) or *Ceanothus megacarpus* (without significant cover of *Cercocarpus betuloides*). However, now with a broader regional perspective, it is becoming clear that these entities are really more generally defined by the presence of a single characteristic species that may or may not have shared dominance with a less characteristic species. In the above examples, *E. fasciculatum-E. farinosa* has been subsumed under the *E. farinosa* Alliance, the *C. megacarpus-C. betuloides* Alliance has been subsumed under the *C. megacarpus* Alliance, and the *Ceanothus megacarpus-Rhamnus ilicifolia* Alliance has been subsumed under the *C. megacarpus* Alliance.

There are various lines of reasoning used to make these decisions. However, central to most of them are a broader understanding of the geographic distribution and internal variation of each of the associations defined within these alliances. If a single mixed alliance has been named, it would have to have a broad regional distribution of the codominant species with further subregional variations of the associations to be substantiated as a codominant alliance. One example of this is the *Artemisia californica–Eriogonum fasciculatum* Alliance, which occurs from San Diego County and northwestern Baja, north to the Diablo Range of Alameda County in California.

One of the great benefits of collecting so many samples of vegetation stands in this current project is that we can now see a more complete approximation in the range of cover of species and environmental conditions for each alliance and association. Thus, we have a better sense of where the important "breaks" in species composition are in these patterns. We can also compare similar vegetation samples from other similar areas away from the Santa Monica Mountains and determine if the characteristics are indeed different or the same. Using these kinds of comparisons for many parts of southern California, we have begun to synthesize some of the complicated patterns that were first described from earlier quantitative efforts and, in some cases, simplify them.

Thus, although *Salvia leucophylla* forms single species dominant stands and codominant stands with *Artemisia californica* in the Santa Monica Mountains, we now believe that both of these situations can be encapsulated within the *Salvia leucophylla* Alliance, rather than establishing a separate alliance for the single dominant and codominant situations. This is a result of *Salvia leucophylla* being relatively geographically restricted, whereby it only dominates in the "Ventura" coastal scrub zone between Santa Barbara and Orange counties (Westman 1981 and Malanson 1984). When *S. leucophylla* makes up an important component of the shrub cover, whether it is the dominant species or is codominant with another species, it is sufficient to define the alliance. On the other hand, a mixed alliance such as *Artemisia californica-Salvia mellifera* has a much broader distribution up and down the California coast ranges and into Baja California. It occurs under different ecological conditions than either the single species alliances *Salvia mellifera* or *Artemisia californica.* For example, in the central coast ranges, there is an association of *A. californica-S. mellifera* defined by codominance of the two shrubs (Evens and San 2004). This same association is also defined for western Riverside County (Klein and Evens 2005) and Orange County (DeSimone and Burke 1992). The wide-ranging consistency of this vegetation is a strong factor in maintaining it as a separate entity from either the *Artemisia californica* or the *Salvia mellifera* Alliance.

The philosophy of this report is consistent with others that have been written for other national parks in California. We require a relatively large number of samples to set high confidence for the existence of an association. In general, we have accepted n = 10 or more as a threshold for high confidence. Any less would set lower confidence, unless the same characteristics of species composition and environmental variables have been previously well-defined in studies elsewhere.

Further revisions are bound to occur in the California state classification as more data is analyzed and compared. As a result of the relatively rigorous definitions at the association level upheld to begin with, it is likely that these modifications

will be made at the alliance level. The associations that are defined currently in this report are well substantiated by large sample sizes with consistent species compositions and relative cover values. The separation of associations into different alliances would only be reasonable if we saw major environmental differences in these alliances. Further revisions could also occur as datasets from different regions are analyzed together to identify and differentiate major environmental patterns of the alliances.

One further refinement of classification rules realized in this project was the treatment of large "emergent" shrubs. In earlier efforts in the California deserts and desert transition areas (Keeler-Wolf et al. 1998 and Thomas et al. 2004), tall shrubs or "dwarf trees," such as *Juniperus californica, Rhus ovata, Cercidium (Parkinsonia) florida, Olneya tesota*, and others, were emphasized in numerical classification when they occurred in association with shorter-statured drought-deciduous desert and semidesert shrubs such as *Encelia farinosa, Salvia apiana, Viguiera parishii,* and *Eriogonum fasciculatum*. Thus, despite a possible higher overall cover of individuals of the shorter drought-deciduous species, the larger, evenly spaced emergent species were found to "drive" the classification by their presence rather than by their total percent cover in a stand. This meant alliances and associations were often named by the larger, less dense emergent species.

Structurally similar situations exist in the Santa Monica Mountains where *Rhus ovata,* and especially *Malosma laurina* occur at relatively low density and cover over a shorter, but higher cover layer of drought-deciduous shrubs such as *Artemisia californica, Encelia californica, Salvia mellifera, S. leucophylla, Eriogonum cinereum,* and *E. fasciculatum*. Thus, the initial classification developed for SAMO before extensive data analysis stressed the presence of such species as *Malosma laurina,* even if they occurred at much lower cover than the associated shorter drought-deciduous shrubs.

This structural relationship was not borne out in the first phase of data analysis. Instead, it became clear that the presence of shrubs such as *Malosma laurina* was often ubiquitous, occurring in many situations that were better defined in many cases by the associated shorter-stature drought-deciduous shrubs. The concept of the *Malosma laurina* Alliance was thus refined to include only those stands where *Malosma* was dominant or codominant with other shrubs (regardless of their stature) in the stand. This is one of many cautionary tales revolving around vegetation classification assumptions based on extrapolating data from seemingly similar situations in different geographies and environments.

Description Writing

Following the analysis of field data and development of the classification and key, association-level descriptions were written and based on field data and available literature. Scientific names of plants follow Hickman (1993) and UCB (2004). Common names follow these sources and USDA (2004). The primary compilers and developers of the data queries were Julie Evens and Anne Klein (California Native Plant Society) and Julie Christian (Santa Monica Mountains NRA). CNPS and TNC staff wrote local descriptions. Todd Keeler-Wolf (California Department of Fish and Game) wrote the keys, introductory material, and edited the description text. Todd Keeler-Wolf and Julie Evens wrote the descriptive sections on range and local and regional comments for descriptions. SAMO staff and Julie Evens edited the introduction, key, and final descriptions.

The following definitions and conventions were used in developing the descriptions and the keys.

1. **Cover:** The primary metric used to quantify the importance/abundance of a particular species or a particular vegetation layer within a stand. It is measured by estimating the aerial extent of the living plants, or the bird's-eye view looking from above, for each category. Cover in this and other California National Park Service vegetation classification and mapping projects uses the concept of "porosity" or foliar cover rather than "opacity" or crown cover. Thus, field crews are trained to estimate the amount of shade produced by the canopy of a plant or a stratum by taking into account the amount of shade it casts excluding the openings it may have in the interstitial spaces (e.g., between leaves or branches). This is assumed to provide a more realistic estimate of the actual amount of shade cast by the individual or stratum which, in turn, relates to the actual amount of light available to individual species or strata beneath it.

2. **Relative cover:** Refers to the amount of the surface of the plot or stand sampled that is covered by one species (or physiognomic group) as compared to (relative to) the amount of surface of the plot or stand covered by all species (in that group). Thus, 50 percent relative cover means that half of the total cover of all species or physiognomic groups is composed of the single species or group in question. Relative cover values are proportional numbers and, if added, total 100 percent for each stand (sample).

3. **Absolute cover:** Refers to the actual percentage of the ground (surface of the plot or stand) that is covered by a species or group of species. For example, *Pinus sabiniana* covers between 5 percent and 10 percent of the

stand. Absolute cover of all species or groups if added in a stand or plot may total greater or less than 100 percent because it is not a proportional number.

4. **Dominant:** Must be in at least 75 percent of the samples, with at least 50 percent relative cover in all samples.

5. **Codominant:** Must be in at least 75 percent of the samples, with at least 30 percent relative cover in all samples.

6. **Consistent/Characteristic/Diagnostic species:** Must be present in at least 75 percent of the samples, with no restriction on cover.

7. **Abundant species:** Must be present in at least 50 percent of the samples, with an average of at least 30 percent relative cover in all samples.

8. **Frequently/Often/Usually occurring species:** Must be present in at least 50 percent of the samples, with no restriction on cover.

9. **Infrequently occurring:** Present in less than 25 percent of the samples.

10. **Sparse:** Used to describe individual layers of vegetation (tree, shrub, herb, or subdivisions of them) where the cover is less than 8 percent absolute cover.

11. **Open:** Used to describe individual layers of vegetation (tree, shrub, herb, or subdivisions of them) where the cover is generally less than 33 percent absolute cover.

12. **Intermittent:** Used to describe individual layers of vegetation (tree, shrub, herb, or subdivisions of them) where there is 33–66 percent absolute cover.

13. **Continuous:** Used to describe individual layers of vegetation (tree, shrub, herb, or subdivisions of them) where there is greater than 66 percent absolute cover.

14. **Emergent:** A plant (or vegetation layer) is considered emergent if it includes a sparse cover of the plant, which rises above a predominant vegetation layer, and is considered a member of the next tallest layer but has an absolute cover < 10%. For example, individual *Quercus agrifolia* trees may comprise an emergent tree layer of 5 percent over a more

dense layer of *Artemisia californica* shrubs; the stand would be considered within the *Artemisia californica* Shrubland Alliance because the total tree cover is < 10% and the shrub cover is > 10%. Further, medium to tall shrubs are not considered emergent over shorter shrubs, but short trees are considered emergent over tall shrubs.

15. **Stand:** Is the basic physical unit of vegetation in a landscape. It has no set size. Some vegetation stands are very small such as wetland seeps, and some may be several square kilometers in size such as desert or forest types. A stand is defined by two main unifying characteristics:

    a. It has *compositional* integrity. Throughout the site, the combination of species is similar. The stand is differentiated from adjacent stands by a discernable boundary that may be abrupt or gradual.

    b. It has *structural* integrity. It has a similar history or environmental setting, affording relatively similar horizontal and vertical spacing of plant species. For example, a hillside forest formerly dominated by the same species but has burned on the upper part of the slope and not the lower is divided into two stands. Likewise, a sparse woodland occupying a slope with shallow rocky soils is considered a different stand from an adjacent slope of a denser woodland/forest with deep, more moist soil and the same species.

16. **Woody plant:** Is any species of plant that has noticeably woody stems. It does not include herbaceous species with woody underground portions such as tubers, roots, or rhizomes.

17. **Tree:** Is a one-stemmed woody plant that normally grows to be greater than 5 meters tall. In some cases, trees may be multiple stemmed following ramifying after fire or other disturbance, but the size of mature plants is typically greater than 5 meters. Undisturbed individuals of these species are usually single stemmed.

18. **Shrub:** Is normally a multistemmed woody plant that is usually between 0.2 meters and 5 meters tall. Definitions are blurred at the low and high ends of the height scales. At the tall end, shrubs may approach trees based on disturbance frequencies (e.g., old-growth resprouting chaparral species such as *Cercocarpus betuloides, Fraxinus dipetala, Heteromeles arbutifolia, Prunus ilicifolia,* and so forth, may frequently attain "tree size"). At the short end, woody perennial herbs or subshrubs of various species are often difficult to categorize into a consistent life-form.

19. **Herbaceous plant:** Is any species of plant that has no main woody stem development and includes grasses, forbs, and dieback perennial species.

20. **Forest:** In the National Vegetation Classification, a forest is defined as a tree-dominated stand of vegetation with 60 percent or greater cover of trees. Most forest alliances tend to have average cover of trees > 60%, but individual stands under certain conditions may drop lower than 60 percent. This is reflective of the "modal" concept of the characteristics of a particular alliance.

21. **Woodland:** In the National Vegetation Classification, woodland is defined as a tree-dominated stand of vegetation with between 25 percent and 60 percent cover of trees. The same notion of "modality" that applies to forest types (#20) also applies here and to the sparsely wooded category (#22).

22. **Sparsely wooded:** These are stands with conspicuous trees (generally at least 10% absolute cover), but less than 25 percent cover may occur over shrubs as the dominant canopy (sparsely wooded shrubland) or herbaceous cover (sparsely wooded herbaceous).

23. **Other Noteworthy Species:** These are listed in the CNPS (2005) Online Inventory of Rare and Endangered Plants and per SAMO (2004). Species were listed in descending order of occurrence within the vegetation type.

24. **Distribution and Nonnative Species:** Local ecological regions and nonnative species were listed in descending order of occurrence within the sample dataset for each vegetation type.

25. **Conservation rank:** Listed by the state NatureServe Heritage Programs. All communities were ranked, though ones without much information were ranked with a "?" after the rank to denote that this rank may change with more information but that the best knowledge to date (sometimes personal observation) was used. Otherwise, hard references were used to place rank. These ranks are the "Global" and "State" ranks as seen below.

    a. **G1** and **S1:** Fewer than six viable occurrences worldwide and/or less than 2000 acres

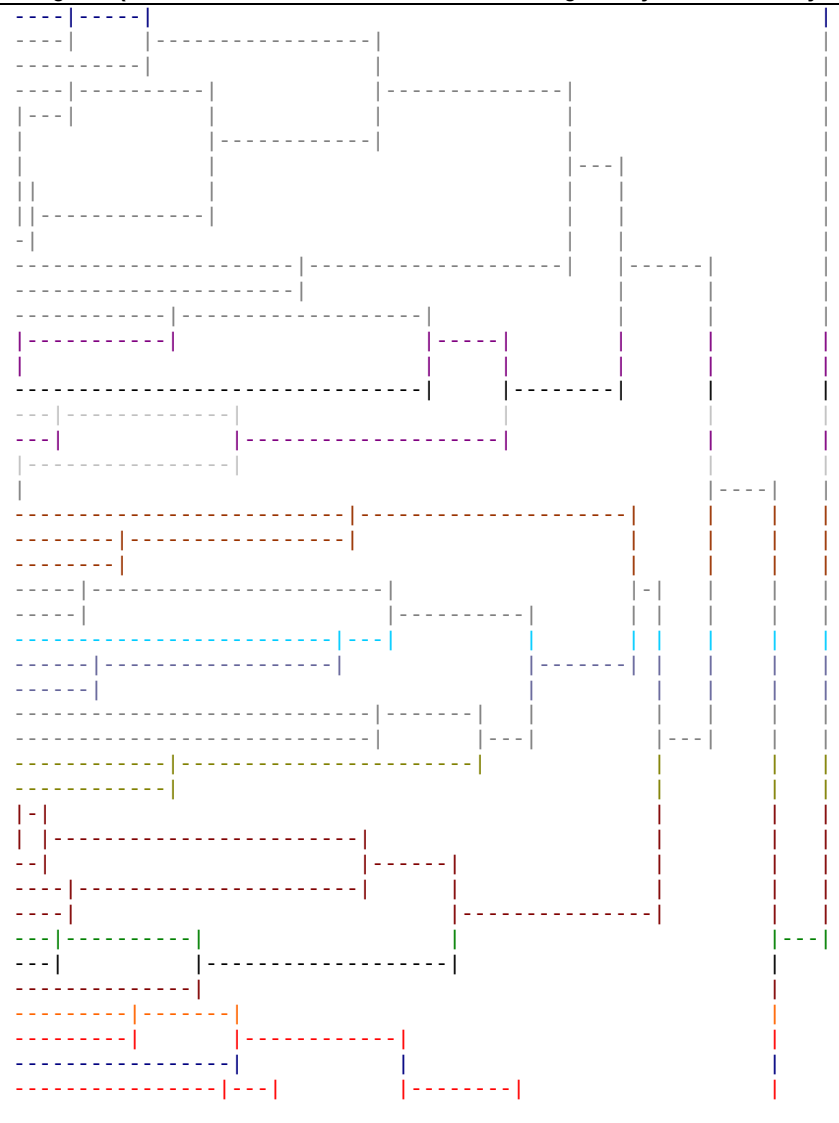
    b. **G2** and **S2:** 6–20 viable occurrences worldwide and/or 2,000–10,000 acres

c. **G3** and **S3:** 21–100 viable occurrences worldwide and/or 10,000–50,000 acres

d. **G4** and **S4:** Greater than 100 viable occurrences worldwide and/or greater than 50,000 acres

26. **Minimum sample size for classification and description:** n = 3. Descriptions of associations with fewer than three samples were attempted if (a) the association was sampled and described by previous authors or (b) the vegetation was confirmed as distinctive and repeatable based on field reconnaissance or by photointerpretation signature.

27. **Sample(s):** Listed by their survey numbers from the vegetation databases and indicated using the following: rapid assessments begin with the alpha code "rap," and accuracy assessments begin with the alpha code AA (an abbreviation for accuracy assessment). Releve samples begin with the code "rap" followed by a numeric code and terminated with the alpha code "rlv." Successive numeric codes follow each of the alpha prefixes.



28. **Con, Avg, Min, Max:** A species table is provided at the end of each alliance or association description. The Con column provides the overall constancy value for each species within all rapid assessments and relevés classified as that vegetation type. The constancy values are between 0 and 100. Species that occurred with at least 20 percent constancy are listed in the table. The Avg column provides the average cover value for each species, as calculated across all samples in that vegetation type. The Min and Max values denote the minimum and maximum cover values of species listed in the table.

RESULTS

The final agglomerative cluster analyses for the classification used data from 3,912 of 4,014 surveys sampled, and it included the 254 most abundant of 544 species sampled in the rapid and accuracy assessments. An example of the cluster analysis with the final sample assignments to association and phase is shown in figure 3, and the final classification is shown in table 1.

In summary, 84 vegetation alliances or unique stands and 204 associations or phases were defined for the project. Of these, 177 types are fully described in this document as natural or seminatural vegetation units. These include associations, alliance-level units where insufficient sample size precluded further

analysis to the association level, and known or presumed rare stands that were not assigned to either associations or alliances (unique stands). Many association descriptions also contain brief descriptions of phases, which indicate further subassociation-level variation.

KEY

The key for distinguishing vegetation types (table 2) is not strictly dichotomous. Because of the diversity of vegetation in the mapping area and to avoid an excessively long document, a series of paired statements (or couplets) was not developed for each option. Instead, sets of characteristics with choices beneath them are provided. The key will first lead the user to the general options, and the individual selections for the vegetation associations will be listed beneath these options. Simply work through the numbered list of types from the more general to the most specific options until the best fit is reached. The choices are identified by a combination of alphanumeric codes, using capital letters, numerals, upper- and lowercase letters, and decimal points to distinguish the different key levels. The most basic, general levels in the key are on the left side of the alphanumeric code, and the most specific are on the right side. This coding system in the key relates to a series of left indentations. Thus, down the left-hand side of the pages are the major groupings; nested within them are the subgroupings. Phases, if present, are listed directly below the association in the key with a brief description. Mapping units (defined as an informal, visually distinct structural assemblage of plants that does not correlate directly with a floristically defined alliance, association, or phase used by the photointerpreters), are also defined where appropriate herein.

The preliminary key will direct you to the major groups, such as forest/woodland, shrubland, and herbaceous, with the more specific choices beneath them. The more specific lists within these are generally based on presence/absence or dominance/subordinance of species until arriving at the optimum choice. *Please note: Since there may be more than two alternatives in a group, be sure to work through all of the options in a list before you decide what is the best choice.*

Table 2: Field key to the defined vegetation associations of the Santa Monica Mountains and Simi Hills area, Ventura and Los Angeles counties, California.

Class A. Vegetation with an overstory of trees (at least 5 m tall). Absolute tree canopy cover is generally >10% but occasionally may be < 10% over a denser understory of shrub and/or herbaceous species. If the latter, trees are evenly distributed across the stand and are ecologically significant members of the stand (stand is thus "characterized" by trees, even if not "dominated" by them). = **Tree-Overstory Vegetation**

Class B. Vegetation characterized by woody shrubs in the canopy. Tree species, if present, generally total < 10% absolute cover. Herbaceous species may total higher cover than shrubs. Shrubs are usually at least 10% cover. = **Shrub-Overstory Vegetation**

Class C. Vegetation characterized by nonwoody, herbaceous species in the canopy including grass, graminoid, and broad-leaved herbaceous species. Shrubs, if present, usually comprise < 10% absolute cover. Trees, if present, generally compose < 5% absolute cover. = **Herbaceous Vegetation**

Class A. Tree-Overstory Vegetation

Group I: Woodlands and forests characterized by needle or scale-leaved conifer trees including pine *(Pinus).* The conifers may only occur intermittently in the overstory and may be associated with tree oaks or shrubs.

I.A. The overstory is dominated by pine *(Pinus)* or other coniferous trees (none native to the mapping area) alone or in shared dominance with broadleaf evergreen trees or shrubs.

> **I.A.1.** Introduced pine (*Pinus* sp.) or other conifers occur as the dominant tree or co-occurs with other tree species in an open overstory, associated with roadsides and human habitation. (Note: This is not a vegetation type since all occurrences are plantations.)
>
> ***Pinus* mapping unit (9520)**

Group II. Woodlands and forests characterized mainly by broad-leaved evergreen and deciduous tree species such as oaks *(Quercus),* willows *(Salix),* bay *(Umbellularia californica),* California walnut *(Juglans californica),* and California sycamore *(Platanus racemosa).*

II.A. California sycamore is the sole dominant tree in the canopy or shares dominance with coast live oak or willows, which may be in the canopy or subcanopy.

***Platanus racemosa* Alliance (1450)**

II.A.1. California sycamore is the sole dominant tree over either a sparse understory of shrubs and herbs or dense annual grasses and herbs.

II.A.1.a. California sycamore is the sole dominant tree with no characteristic species in either the canopy or understory.

Platanus racemosa* South Coast Intermittent Stream Association *(*6451*)

II.A.1.b. California sycamore is the sole dominant tree in the overstory. The understory has a significant mixed cover of grasses, herbs, and shrubs.

***Platanus racemosa*/Annual Grass-Herb Association (1456)**

II.A.2. Coast live oak usually shares dominance with California sycamore in the overstory (they either may be codominant or dominant). Arroyo willow may be present.

II.A.2.a California sycamore and coast live oak occur in the canopy with no significant cover of any other large riparian trees or shrubs.

***Platanus racemosa-Quercus agrifolia* South Coast Association (1452)**

II.A.2.b. Coast live oak usually shares dominance with California sycamore in the overstory. In the understory, arroyo willow occurs with mule fat *(Baccharis salicifolia)* and other species.

***Platanus racemosa-Quercus agrifolia-Salix lasiolepis* Association (6452)**

II.A.2.c. Coast live oak usually shares dominance with California sycamore in the overstory. In the understory, mule fat *(Baccharis salicifolia*) dominates, and mugwort *(Artemisia douglasiana)* is usually present.

***Platanus racemosa-Quercus agrifolia/Baccharis salicifolia/ Artemisia douglasiana* South Coast Association (1458)**

II.B. California walnut *(Juglans californica)* provides an open to intermittent tree overstory canopy (in some cases it may be a large shrub). It may co-occur and codominate with coast live oak. Shrubs of either chaparral *(Ceanothus* sp.,

Heteromeles arbutifolia, etc.) or coastal sage scrub *(Artemisia californica, Salvia leucophylla)* as well as annual or perennial grasses may occur in the understory.

***Juglans californica* Alliance (1310)**

II.B.1. California walnut is the sole dominant tree (or large shrub) in the overstory. Shrubs are sparse to open, while annual grasses and herbs are abundant in the understory.

***Juglans californica*/Annual Grass-Herb Association (1312)**

II.B.2. California walnut is dominant in the tree overstory, and stands contain significant and obvious shrubs of either chaparral or coastal scrub affinities *(Ceanothus spinosus, Malosma laurina, Heteromeles arbutifolia, Artemisia californica, Salvia leucophylla)* in the understory subcanopy.

II.B.2.a. California walnut is the sole dominant tree (or occasionally, large shrub) and greenbark ceanothus is strongly dominant in the shrub layer.

***Juglans californica/Ceanothus spinosus* Association (1315)**

II.B.2.b. Laurel sumac is dominant in the shrub understory, although a number of other shrubs (some often early seral such as *Malacothamnus fasciculatus*) may be present at low cover.

***Juglans californica/Malosma laurina* Association (1314)**

II.B.2.c. California sagebrush is codominant to dominant often with purple sage in the shrub understory. Giant wild rye is usually present in significant cover in the herb layer. California walnut is dominant in the overstory.

***Juglans californica/Artemisia californica/Leymus condensatus* Association (1317)**

II.B.2.d. Toyon is the dominant shrub in the understory with coast live oak present but always subdominant to California walnut in the tree layer. Sugar bush and several other typically chaparral shrubs are usually present along with toyon in the shrub layer.

***Juglans californica/Heteromeles arbutifolia* Association (6312)**

II.B.3. California walnut is subdominant to codominant with coast live oak in the overstory, and the understory may be open and grassy or may have shrub layer with poison oak.

***Quercus agrifolia-Juglans californica* Association (1115)**

Note: Two phases of this association occur: One in which the shrub layer is low in cover (trace cover of poison oak) while the herbaceous layer is usually moderately to highly developed, and another in which the shrub layer has moderate to high cover of poison oak and other shrub species such as toyon and elderberry.

***Quercus agrifolia-Juglans californica* Phase (1115)**

***Juglans californica-Quercus agrifolia/Toxicodendron diversilobum* Phase (6311)**

II.C. Oaks (either valley oak or coast live oak) are the dominant trees in the overstory.

II.C.1. Valley oak is the dominant or conspicuous tree occurring as a sole dominant or as codominant with coast live oak and/or arroyo willow.

***Quercus lobata* Alliance (1320)**

II.C.1.a. Valley oak occurs in nonriparian settings over an understory with sparse shrubs and characterized by annual grasses and herbs, with or without coast live oak.

II.C.1.a.i. Valley oak is the sole dominant tree over annual grasses and herbs. Coast live oak and/or walnut may be present but in total never more than half the cover of valley oak.

***Quercus lobata*/Annual Grass-Herb Association (1321)**

II.C.1.a.ii. Valley oak occurs with coast live oak as a codominant or subdominant in the tree layer over annual grasses and herbs.

***Quercus lobata-Quercus agrifolia*/Annual Grass-Herb Association (1323)**

II.C.1.b. Valley oak occurs with shrubby or tree-sized arroyo willow in riparian settings.

***Quercus lobata-Salix lasiolepis* Association (1324)**

II.C.2. Coast live oak occurs as the dominant tree in the canopy, while California sycamore and/or California bay may be subdominant to codominant.

***Quercus agrifolia* Alliance (1110)**

II.C.2.a. Willows (*Salix lasiolepis* primarily) are subdominant trees with coast live oak in riparian or ravine settings.

III.C.2.a.i. Arroyo willow and/or red willow are subdominant overstory or understory trees with coast live oak. Riparian shrubs and herbs may also be present, including mule fat, mugwort, and rorippa.

***Quercus agrifolia-Salix lasiolepis* Association (6114)**

II.C.2.b. Coast live oak is usually the sole dominant tree species in the overstory in upland (usually nonriparian) settings over a variety of understory layers from grassy to scrubby.

II.C.2.b.i. While the overstory is dominated solely by coast live oak, the understory is sparse to low in cover and may have occasional shrubs or herbs.

***Quercus agrifolia* South Coastal Association (6122)**

II.C.2.b.ii. While the overstory is dominated solely by coast live oak, the understory is primarily dominated by annual grasses and herbs.

***Quercus agrifolia*/Annual Grass-Herb Association (1111)**

II.C.2.b.iii. While the overstory is dominated solely by coast live oak, the understory is primarily dominated by poison oak and/or bush monkey flower in one layer and annual grasses and herbs in another layer, though the shrub layer usually has higher understory cover.

***Quercus agrifolia/Toxicodendron diversilobum* Association (1117)**

Note: This association includes the following phase, which may contain poison oak at sparse to moderate cover but also has bush monkey flower at moderate to high cover.

***Quercus agrifolia/Mimulus aurantiacus* Phase (6113)**

II.C.2.b.iv. While the overstory is dominated solely by coast live oak, the understory is primarily dominated by toyon. Laurel sumac may be present. If poison oak is present, cover is less than toyon.

***Quercus agrifolia/Heteromeles arbutifolia* Association (6117)**

Note: This association includes the following phase, which contains toyon and laurel sumac at moderate cover.

***Quercus agrifolia/Malosma laurina* Phase (6116)**

II.C.2.b.v. Chamise occurs as an open to dense understory under an open canopy of coast live oak.

***Quercus agrifolia/Adenostoma fasciculatum* Association (6115)**

II.C.2.b.vi. Greenbark ceanothus occurs as a tall understory shrub associated with an open to intermittent canopy of coast live oak.

***Quercus agrifolia/Ceanothus spinosus* Association (1118)**

II.C.2.b.vii. Scrub oak occurs as the principal understory shrub in an open to intermittent overstory of coast live oak.

***Quercus agrifolia/Quercus berberidifolia* Association (6112)**

II.C.2.b.viii. Both purple sage and California sagebrush occur as understory shrubs to an open to intermittent canopy of coast live oak.

***Quercus agrifolia/Salvia leucophylla-Artemisia californica* Association (1116)**

II.C.2.c. California bay is subdominant to codominant with coast live oak in the overstory. The understory may be open and grassy or may include a moderate to high cover of shrub cover.

II.C.2.c.i. Hairy leaf ceanothus occurs as a tall understory shrub associated with an open to intermittent canopy of coast live oak and frequently California bay. If poison oak is present, it is trace in cover.

***Quercus agrifolia-Umbellularia californica/Ceanothus oliganthus* Association (1119)**

II.C.2.c.ii. The understory is usually open, though shrubs such as poison oak, toyon, and greenbark ceanothus may also be present at low to moderate cover.

***Quercus agrifolia-Umbellularia californica* Association (1114)**

Note: This association includes the following two phases: One contains poison oak at moderate cover but may also have other shrub species at low to moderate cover, and the other contains no poison oak.

***Quercus agrifolia-Umbellularia californica/Toxicodendron diversilobum* Phase (6119)**
***Quercus agrifolia-Umbellularia californica* Phase (1114)**

II.D. One or more willow species are the primary tree(s) in the riparian overstory. (Note: Although some willows may be considered shrubs in this area, most are tall enough to be identified as tree willows, and there is no separation of tree and shrub willow categories in this key.)

II.D.1. Arroyo willow *(S. lasiolepis)* is the dominant tree in the canopy or is codominant with red willow *(Salix laevigata)* in the canopy.

II.D.1.a. Red willow occurs with arroyo willow as a sub- or codominant in the overstory.

II.D.1.a.i. California blackberry and mugwort *(Artemisia douglasiana)* are usually present in the understory with a variety of other herbs and shrubs.

***Salix laevigata-Salix lasiolepis/Artemisia douglasiana-Rubus ursinus*/Annual Grass-Herb Association (1413)**

II.D.1.a.ii. Red willow and arroyo willow are co- or subdominant, but stands lack California blackberry and/or mugwort.

***Salix laevigata-Salix lasiolepis* Association (1410)**

II.D.1.a.iii. Red willow and arroyo willow both occur in the tree or tall shrub layer with mule fat as the characteristic shorter shrub.

***Salix laevigata-Salix lasiolepis/Baccharis salicifolia* Association (1412/1432)**

II.D.2. Riparian shrublands or woodlands in which arroyo willow *(Salix lasiolepis)* is dominant. An emergent and sparse tree layer may also be present.

***Salix lasiolepis* Alliance (1430)**

II.D.2.a. Laurel sumac is a common and characteristic shrub associating with the overstory-dominant arroyo willow, occasionally seen on seeps and bluffs along the immediate coast.

***Salix lasiolepis/Malosma laurina* Association (1433)**

II.D.2.b. Mule fat is a characteristic subdominant or codominant with arroyo willow.

***Salix lasiolepis/Baccharis salicifolia* Association (1414)**

II.D.3. The overstory is dominated by the clonal shrubby to short tree-sized narrow-leaved willow. Stands are uncommon and usually small in the study area.

***Salix exigua* Alliance (3110)**

II.D.4. Red willow is the sole dominant.

***Salix laevigata* Alliance (1420)**

II.E. White alder *(Alnus rhombifolia*) is the dominant or, most commonly, it shares dominance with other trees. It is usually restricted to permanently flowing streams close to the coast.

***Alnus rhombifolia* Alliance (1440)**

II.E.1. White alder is codominant to subdominant with California sycamore.

***Alnus rhombifolia-Platanus racemosa* Association (1441)**

II.F. A species of *Eucalyptus* dominates in the tree/shrub canopy, though there may be a minor presence of native trees/shrubs. Most stands are planted and noninvasive in this study area.

***Eucalyptus* Alliance (9510)**

II.G. California bay occurs as a tree or tall shrub usually dominant or codominant with coast live oak, California walnut, California sycamore, white alder, or taller mesic chaparral shrubs such as greenbark or hairy leaf ceanothus *(Ceanothus spinosus* or *C. oliganthus).*

***Umbellularia californica* Alliance (1010)**

II.G.1. California bay dominates or codominates in upland settings and not usually adjacent to streams or bottomlands.

II.G.1.a. California bay is either a shrub or a tree of rocky upland settings associated with hairy leaf ceanothus and usually associated with coast live oak in lower cover.

***Umbellularia californica/Ceanothus oliganthus* Association (1012)**

II.G.2. California bay occurs in stands in convex upper slopes and ravines or in true riparian settings adjacent to streams and associated with California walnut, California sycamore, or white alder.

II.G.2.a. California bay occurs along perennial streams with white alder, rare and local in the Santa Monica Mountains.
***Umbellularia californica-Alnus rhombifolia* Association (1013)**

II.G.2.b. California bay occurs along streams or in ravines with codominance to a low cover presence of California sycamore.
***Umbellularia californica-Platanus racemosa* Association (1014)**

II.G.2.c. California bay occurs with California walnut as a frequent subdominant and greenbark ceanothus as the principal understory shrub, usually in ravines and concavities on slopes.
***Umbellularia californica-Juglans californica/Ceanothus spinosus* Association (1011)**

II.H. Interior live oak occurs as a dominant or codominant in the tree/shrub overstory.

***Quercus wislizeni* Alliance (2560)**

Note: In this study the few known stands of *Quercus wislizeni* Alliance appear to be dominated by shrubby individuals and have been placed in the Shrub-Overstory Vegetation section of this classification. For thoroughness and assuming that there may be some stands that reach near tree-size, they may be keyed here or in the shrub key that follows.

Class B. Shrub-Overstory Vegetation

Group I: Shrublands are dominated by sclerophyllous temperate broad-leaved shrubs (with leaves hardened by a waxy cuticle). They are dominated by typical chaparral shrub genera including chamise *(Adenostoma fasciculatum*), manzanita *(Arctostaphylos*), *Ceanothus,* mountain mahogany *(Cercocarpus),* scrub oaks *(Quercus),* coffeeberry *(Rhamnus),* and so forth. This group also includes vegetation dominated or codominated by large broad-leaved evergreen species such as *Malosma laurina* and *Rhus* spp., which may be associated with shorter nonsclerophyll shrubs.

I.A. A postfire transition scrub dominated by bush poppy *(Dendromecon rigida),* usually with chamise *(Adenostoma fasciculatum)* or other chaparral shrubs present. Note: Bush poppy is considered by some as a drought-deciduous species and may also be keyed in Group II of this shrub key.

***Dendromecon rigida* Alliance,**
***Dendromecon rigida* Association (3350)**

I.B. The shrubland overstory is dominated primarily by one species of shrub oak (*Quercus*) or has shared dominance with other chaparral shrub species such as chamise.

I.B.1. Scrub oak *(Quercus berberidifolia)* usually occurs as a dominant or, if it codominates, it is not codominant with chamise nor birch leaf mountain mahogany.

***Quercus berberidifolia* Alliance (2160)**

I.B.1.a. Scrub oak occurs as the sole dominant in the shrub layer. Other shrubs may occur as subdominants.

***Quercus berberidifolia* Association (2161)**

Note: This association is complex including two phases with a small but constant cover of either chamise or toyon.

***Quercus berberidifolia-Heteromeles arbutifolia* Phase (2164)**
***Quercus berberidifolia-Adenostoma fasciculatum* Phase (2163)**

I.B.1.b. Greenbark ceanothus *(C. spinosus)* characteristically occurs as a subdominant or codominant with scrub oak.

***Quercus berberidifolia-Ceanothus spinosus* Association (2167)**

I.B.2. Scrub oak codominates with chamise (chamise and scrub oak each > 15% relative cover in the shrub layer), other shrubs in the stands are significantly less cover.

***Adenostoma fasciculatum-Quercus berberidifolia* Alliance (2580)**
***Adenostoma fasciculatum-Quercus berberidifolia* Association (2581)**

I.B.3. Scrub oak *(Quercus berberidifolia)* usually occurs as a codominant or subdominant with birch leaf mountain mahogany (typically both with 10% cover).

***Quercus berberidifolia-Cercocarpus betuloides* Alliance (2590)**
***Quercus berberidifolia-Cercocarpus betuloides* Association (2591)**

I.B.4. The overstory is dominated by interior live oak. Stands are uncommon and small and are at the upper elevations of the Santa Monica Mountains, usually in rocky settings.

***Quercus wislizeni* var. *frutescens* Alliance (2560)**

I.C. The overstory is dominated by lemonade berry *(Rhus integrifolia),* holly leaf cherry *(Prunus ilicifolia),* sugar bush *(Rhus ovata),* or toyon *(Heteromeles arbutifolia),* and the shrubs may have shared dominance with other evergreen, coastal scrub, or succulent shrubs.

I.C.1. Lemonade berry occurs as the dominant shrub in an open to intermittent overstory while other shrubs (mostly nonchaparral coastal scrub species) may be present at low cover.

***Rhus integrifolia* Alliance (2150)**

I.C.1.a. Lemonade berry strongly dominates the shrub layer, though the shrub layer is typically open to intermittent in cover.

***Rhus integrifolia* Association (2153)**

Note: This is a complex association including four phases: one with a constant low cover of toyon; one with nearly pure shrub cover of lemonade berry; one with a postfire phase with a constant low cover of bush mallow; and one with a cover of laurel sumac and sagebrush.

***Rhus integrifolia-Heteromeles arbutifolia* Phase (2158)**
***Rhus integrifolia* Phase (2153)**
***Rhus integrifolia-Malacothamnus fasciculatus* Phase (7153)**
***Rhus integrifolia-Malosma laurina-Artemisia californica* Phase (7156)**

I.C.1.b. Lemonade berry is conspicuous in the shrub layer but regularly has smaller, usually drought-deciduous coastal scrub shrubs associating with it.

I.C.1.b.i. California sagebrush and/or ashy buckwheat are subdominants and may occur in equal to higher cover (in total) to lemonade berry.

***Rhus integrifolia-Artemisia californica-Eriogonum cinereum* Association (7157)**

Note: This is a complex association including three phases that contain lemonade berry mixed with drought deciduous shrubs; one with California sagebrush and purple sage; one with California sagebrush and ashy buckwheat; and another, often of steep bluffs, with ashy buckwheat and low cover of coast yucca and giant coreopsis.

***Rhus integrifolia-Artemisia californica-Salvia leucophylla* Phase (2155)**
***Rhus integrifolia-Artemisia californica-Eriogonum cinereum* Association Phase (7157)**
***Rhus integrifolia-Eriogonum cinereum-Yucca whipplei-Coreopsis gigantea* Phase (7155)**

I.C.1.b.ii. Coast prickly pear cactus and ashy buckwheat are conspicuous species associated with lemonade berry, usually of coastal bluffs along the western end of the Santa Monica Mountains and volcanic slopes above the Oxnard Plain.

***Rhus integrifolia-Opuntia* spp.-*Eriogonum cinereum* Association (2151)**

I.C.2. Holly leaf cherry occurs as a dominant or codominant shrub with other shrubs such as toyon in an open to intermittent overstory. Usually found in steep, mesic concavities or near rock outcroppings.

***Prunus ilicifolia* Alliance (2120)**

I.C.2.a. Toyon occurs as a subdominant to codominant shrub in the overstory.

***Prunus ilicifolia-Heteromeles arbutifolia* Association (2121)**

I.C.3. Toyon occurs as a codominant to dominant shrub in an open to continuous shrub overstory.

***Heteromeles arbutifolia* Alliance (2130)**

I.C.3.a. Laurel sumac frequently occurs as a subdominant or codominant shrub with toyon in the overstory, and there may have several other shrub species (including *Rhus* spp.) associated in lower cover.

***Heteromeles arbutifolia-Malosma laurina* Association (2138)**

Note: This is a complex association including five phases, each with a mixture of toyon and laurel sumac along with different shrubs as subdominants as indicated in the phase names. The *Heteromeles* phase has virtually no other major shrub species.

***Heteromeles arbutifolia-Malosma laurina-Artemisia californica-Mimulus aurantiacus* Phase (2135)**
***Heteromeles arbutifolia-Malosma laurina-Cercocarpus betuloides* Phase (2136)**
***Heteromeles arbutifolia-Malosma laurina-Quercus agrifolia* Phase (2137)**
***Heteromeles arbutifolia-Malosma laurina-Salvia mellifera-Rhus* spp. Phase (2138)**
***Heteromeles arbutifolia* Phase (2137)**

I.C.4. Sugar bush occurs as a dominant or codominant or sometimes may be subdominant to California sagebrush and/or purple sage in an open to intermittent shrub overstory with other shrub species.

***Rhus ovata* Alliance (2190)**

I.C.4.a. Sugar bush is strongly dominant with a significantly lower cover of other shrubs.

***Rhus ovata* Association (2193)**

I.C.4.b. Sugar bush tends to codominate with purple sage and/or California sagebrush.

***Rhus ovata-Salvia leucophylla-Artemisia californica* Association (2192)**

I.D. Birch leaf mountain mahogany occurs as a dominant or codominant with other chaparral shrubs.

I.D.1. Birch leaf mountain mahogany occurs as a dominant or codominant with other chaparral shrubs in an open to continuous shrub overstory.

***Cercocarpus betuloides* Alliance (2110)**

I.D.1.a. Birch leaf mountain mahogany usually occurs as a strong dominant, though shrubs such as toyon may occur as subdominants.

***Cercocarpus betuloides* Association (2114)**

I.D.1.b. Birch leaf mountain mahogany is codominant with chamise, although other shrubs may occur in lower cover, usually on upper northerly facing steep slopes adjacent to ridges.

***Cercocarpus betuloides-Adenostoma fasciculatum* Association (2115)**

I.D.1.c. Birch leaf mountain mahogany is codominant with greenbark ceanothus, usually on lower, more mesic slope positions than the former association.

***Cercocarpus betuloides-Ceanothus spinosus* Association (2113)**

I.D.1.d. Birch leaf mountain mahogany is dominant to codominant with laurel sumac and California sagebrush, usually found in coastal areas.

***Cercocarpus betuloides-Malosma laurina-Artemisia californica* Association (2117)**

Note: This association is complex and includes two phases, one where laurel sumac is more of a clear codominant with birch leaf mountain mahogany while California sagebrush is subdominant, and another where laurel sumac and sagebrush

are subdominant and *Melica imperfecta* is a conspicuous understory grass.

***Cercocarpus betuloides-Malosma laurina* Phase (2117)**
***Cercocarpus betuloides-Malosma laurina-Artemisia californica/Melica imperfecta* Phase (2111)**

I.E. Laurel sumac usually occurs as a codominant to dominant in an open to intermittent shrub overstory often with nonsclerophyllous shrubs such as California buckwheat, black sage *(Salvia mellifera),* or California sagebrush.

***Malosma laurina* Alliance (2140)**

I.E.1. Laurel sumac is strongly dominant with significantly lower cover of all other shrub species, usually forming an open to intermittent shrub cover.

***Malosma laurina* Association (7142)**

Note: This association includes a phase where annual grasses and herbs predominate in the understory, and another phase where the herbaceous layer is low in cover.

***Malosma laurina*/Annual Grass-Herb Phase (2145)**
***Malosma laurina* Phase (7142)**

I.E.2. California buckwheat occurs as a codominant short shrub along with the taller laurel sumac. Other shrubs may occur at low cover.

***Malosma laurina-Eriogonum fasciculatum* Association (21423)**

Note: This complex association includes three phases: one with other coastal sage species such as California sagebrush, one with essentially only the two nominate species in the shrub layer, and another with chaparral species such as big pod ceanothus as low cover associates.

***Malosma laurina-Eriogonum fasciculatum-Artemisia californica*/Annual Grass-Herb Phase (3382)**
***Malosma laurina-Eriogonum fasciculatum* Phase (21423)**
***Malosma laurina-Eriogonum fasciculatum-Heteromeles arbutifolia-Ceanothus megacarpus* Phase (3383)**

I.E.3. Black sage is usually codominant or a major subdominant shrub with laurel sumac. Ashy buckwheat is not present in significant cover.

***Malosma laurina-Salvia mellifera* Association (2148)**

I.E.4. Sugar bush and big pod ceanothus are constant subdominants with laurel sumac.

***Malosma laurina-Rhus ovata-Ceanothus megacarpus* Association (21415)**

I.E.5. Ashy buckwheat is a codominant to subdominant with laurel sumac. Several other shrubs may be associated at lower cover.

***Malosma laurina-Eriogonum cinereum* Association (2141)**

Note: This complex association includes five phases each with different subdominants or, in one case, only with the two nominate species as codominants. At least two are postfire phases indicated by the presence of either bush mallow or deerweed.

***Malosma laurina-Eriogonum cinereum-Lotus scoparius* Phase (7144)**
***Malosma laurina-Eriogonum cinereum-Salvia mellifera* Phase (7141)**
***Malosma laurina-Malacothamnus fasciculatus-Eriogonum cinereum-Salvia mellifera* Phase (7146)**
***Malosma laurina-Rhus integrifolia-Eriogonum cinereum-Artemisia californica* Phase (21413)**
***Malosma laurina-Eriogonum cinereum* Phase (2141)**

I.E.6. Laurel sumac codominates or dominates with California sagebrush. Stands may or may not include purple sage as a subdominant.

***Malosma laurina-Artemisia californica* Association (7148)**

Note: This complex association may include stands where purple sage occurs as a subdominant along with the other two nominate shrubs or stands where the nominate species are the only significant shrub cover.

***Malosma laurina-Artemisia californica-Salvia leucophylla* Phase (2142)**
***Malosma laurina-Artemisia californica* Phase (7148)**

I.F. A manzanita species occurs as a dominant in the shrub overstory.

I.F.1. Eastwood manzanita occurs as the sole dominant in the shrub overstory, usually making up at least two-thirds of the total shrub cover, uncommon at the upper elevations in the Santa Monica Mountains.

***Arctostaphylos glandulosa* Alliance,**
***Arctostaphylos glandulosa* Association (2550)**

I.F.2. Big berry manzanita occurs as a dominant in the shrub overstory, most common in the Simi Hills portion of the study area.

***Arctostaphylos glauca* Alliance (2540)**

I.G. The overstory is dominated by *Ceanothus* alone or in shared dominance with other broadleaf evergreen shrubs.

I.G.1. Hoary leaf ceanothus *(Ceanothus crassifolius)* usually occurs as a dominant or as a codominant with species such as laurel sumac.

***Ceanothus crassifolius* Alliance (2060)**

I.G.1.a. Hoary leaf ceanothus occurs as the sole dominant species, and other chaparral shrubs, if present, are relatively low in cover.

***Ceanothus crassifolius* Association (2063)**

I.G.1.b. Laurel sumac occurs as a subdominant to codominant in the shrub overstory.

***Ceanothus crassifolius-Malosma laurina* Association (2065)**

I.G.2. Wedge leaf ceanothus *(Ceanothus cuneatus)* occurs as the dominant in an open to intermittent shrub overstory.

***Ceanothus cuneatus* Alliance (2520)**

I.G.2.a. Wedge leaf ceanothus occurs with a constant subordinate cover of scrub oak, and stands are scattered throughout the central portion of the Santa Monica Mountains.

***Ceanothus cuneatus-Quercus berberidifolia* Association (2521)**

I.G.3. Big pod ceanothus *(Ceanothus megacarpus)* is dominant in an intermittent to continuous shrub overstory.

***Ceanothus megacarpus* Alliance (2080)**

I.G.3.a. Big pod ceanothus is the sole dominant shrub with no other species at significant cover in the stands.

***Ceanothus megacarpus* Association (2081)**

I.G.3.b. Big pod ceanothus is dominant with chamise subdominant to codominant.

***Ceanothus megacarpus-Adenostoma fasciculatum* Association (2083)**

Note: This complex association includes a phase with black sage as a subdominant along with chamise and a phase where just the two nominate species are present in the shrub layer.

***Ceanothus megacarpus-Adenostoma fasciculatum-Salvia mellifera* Phase (7083)**
***Ceanothus megacarpus-Adenostoma fasciculatum* Phase (2083)**

I.G.3.c. Big pod ceanothus occurs as a dominant along with redshank as a subdominant.

***Ceanothus megacarpus-Adenostoma sparsifolium* Association (2082)**

I.G.3.d. Big pod ceanothus occurs as a dominant with birch leaf mountain mahogany as a subdominant. May also include scrub oak in the stand.

***Ceanothus megacarpus-Cercocarpus betuloides* Association (2084)**

I.G.3.e. Big pod ceanothus dominates with a subdominance of laurel sumac. May have other shrubs in lower cover such as chamise and black sage.

***Ceanothus megacarpus-Malosma laurina* Association (2087)**

Note: This complex association includes two phases: one with chamise and other chaparral species and another with the two nominate species providing almost all of the cover.

***Ceanothus megacarpus-Malosma laurina-Adenostoma fasciculatum Mixed Chaparral* Phase (7081)**
***Ceanothus megacarpus-Malosma laurina* Phase (2087)**

I.G.3.f. Big pod ceanothus dominates with a subdominance of black sage.

Ceanothus megacarpus-Salvia mellifera Association (7085)

I.G.3.g. Big pod ceanothus dominates or codominates with chaparral mallow.

***Malacothamnus fasciculatus-Ceanothus megacarpus* Association (3288)**

I.G.3.h. Big pod ceanothus is the dominant or codominant along with the subdominant to codominant greenbark ceanothus.

***Ceanothus spinosus-Ceanothus megacarpus* Association (2091)**

I.G.4. Hairy leaf ceanothus *(Ceanothus oliganthus)* is usually dominant in an open to continuous shrub overstory, typical in mesic sites at upper elevations or interior locations in the study area.

***Ceanothus oliganthus* Alliance (2070)**

I.G.4.a. Hairy leaf ceanothus is the dominant shrub, no other species provides high cover in the shrub layer.

***Ceanothus oliganthus* Association (2072)**

I.G.4.b. Hairy leaf ceanothus is the dominant shrub, but redshank is a regular subdominant.

***Ceanothus oliganthus-Adenostoma sparsifolium* Association (2078)**

I.G.4.c. Toyon and/or sugar bush are subdominant to hairy leaf ceanothus.

***Ceanothus oliganthus-Heteromeles arbutifolia-Rhus ovata* Association (2076)**

I.G.4.d. Scrub oak is subdominant to hairy leaf ceanothus.

***Ceanothus oliganthus-Quercus berberidifolia* Association (2077)**

I.G.5. Stands are dominated by the large mesophytic greenbark ceanothus.

***Ceanothus spinosus* Alliance (2090)**

I.G.5.a. Greenbark ceanothus strongly dominates the shrub overstory with only minor cover of other shrubs including toyon, holly leaf cherry, or laurel sumac.

***Ceanothus spinosus* Association (2092)**

Note: This complex association includes three phases based on the subordinate shrub species. In one case greenbark ceanothus is the sole dominant.

***Ceanothus spinosus-Heteromeles arbutifolia-Prunus ilicifolia* Phase (2094)**
***Ceanothus spinosus-Malosma laurina* Phase (2097)**
***Ceanothus spinosus* Phase (2090)**

I.G.5.b. Greenbark ceanothus is the dominant or codominant along with the subdominant to codominant big pod ceanothus.

***Ceanothus spinosus-Ceanothus megacarpus* Association (2091)**

I.H. The overstory is dominated by chamise alone or in shared dominance with other chaparral or coastal scrub species in an open to continuous shrub canopy.

I.H.1. Chamise occurs as a dominant or as a codominant with laurel sumac, California buckwheat, big pod ceanothus, or other shrubs such as yerba santa or bush monkey flower.

***Adenostoma fasciculatum* Alliance (2010)**

I.H.1.a. Chamise occurs as a sole dominant shrub with no other constant subdominants.

***Adenostoma fasciculatum* Association (2011)**

I.H.1.b. Big pod ceanothus occurs as a codominant or subdominant with chamise.

***Adenostoma fasciculatum-Ceanothus megacarpus* Association (2019)**

I.H.1.c. California buckwheat occurs as a subdominant or codominant with chamise.

I.H.1.c.i. Chamise and California buckwheat occur in an open to intermittent shrub overstory with various mostly nonnative herbs among these two shrubs.

***Adenostoma fasciculatum-Eriogonum fasciculatum* Association (2017)**

Note: This complex association includes the postfire or postdisturbance phases.

***Adenostoma fasciculatum-Eriogonum fasciculatum*/Annual Grass-Herb Phase (2017)**

***Adenostoma fasciculatum-Lotus scoparius-Dendromecon rigida* Phase (7012)**

I.H.1.d. Laurel sumac usually occurs as a codominant with chamise.

***Adenostoma fasciculatum-Malosma laurina* Association (2013)**

I.H.1.d.i Laurel sumac and Chamise are joined with yerba santa in an open to intermittent shrub overstory over annual herbs and grasses.

***Adenostoma fasciculatum-Malosma laurina-Eriodictyon crassifolium*/Annual Grass-Herb Association (7018)**

I.H.1.e. Chamise is dominant to codominant with bush monkey flower.

***Adenostoma fasciculatum-Mimulus aurantiacus* Association (7013)**

I.H.1.f. Chamise is dominant and accompanied by purple sage as a subdominant to occasional codominant.

***Adenostoma fasciculatum-Salvia leucophylla* Association (2018)**

I.H.2. Eastwood manzanita is usually codominant (occasionally subdominant) with chamise in an open to continuous shrub overstory.

***Adenostoma fasciculatum-Arctostaphylos glandulosa* Alliance (2020)**

I.H.2.a. Eastwood manzanita occurs as a codominant with chamise and may have big pod ceanothus as a subdominant.

***Adenostoma fasciculatum-Arctostaphylos glandulosa* Association (2021)**

Note: Included is the variant with big pod ceanothus consistently present at low cover.

Adenostoma fasciculatum-Ceanothus megacarpus-Arctostaphylos glandulosa* Phase *(7017)

I.H.3. Big berry manzanita usually occurs as a codominant with chamise in an intermittent to continuous shrub overstory. Wedge leaf ceanothus, cup leaf ceanothus, and hoary leaf ceanothus are absent or subdominant.

***Adenostoma fasciculatum-Arctostaphylos glauca* Alliance (2530)**

***Adenostoma fasciculatum-Arctostaphylos glauca* Association (2531)**

I.H.4. Hoary leaf ceanothus usually occurs as a codominant with chamise in an open to intermittent shrub overstory locally with other shrubs including laurel sumac.

***Adenostoma fasciculatum-Ceanothus crassifolius* Alliance (2570)**

I.H.4.a. Laurel sumac characteristically occurs as a subdominant or codominant and is lower in cover than hoary leaf ceanothus and chamise.

***Adenostoma fasciculatum-Ceanothus crassifolius-Malosma laurina* Association (2572)**

I.H.5. Wedge leaf ceanothus occurs as a codominant with chamise in an intermittent to continuous shrub overstory. Other shrubs may intermix as subdominants.

***Adenostoma fasciculatum-Ceanothus cuneatus* Alliance (2510)**

I.H.5.a Black sage and laurel sumac occur as subdominants to chamise and wedge leaf ceanothus in an intermittent to continuous shrub overstory.

***Adenostoma fasciculatum-Ceanothus cuneatus-Salvia mellifera-Malosma laurina* Alliance Association (2511)**

I.H.6. Black sage usually occurs as codominant with chamise in an open to continuous shrub overstory. Wedge leaf ceanothus is absent or, if present, < 5% relative cover.

***Adenostoma fasciculatum-Salvia mellifera* Alliance (2030)**

Note: If wedge leaf ceanothus is present at significant cover, see heading I.H.5.

I.H.6.a. Laurel sumac occurs as a subdominant.
Adenostoma fasciculatum-Salvia mellifera-Malosma laurina **Association (2035)**

I.H.6.b. Sugar bush occurs as a subdominant and is consistently lower in cover than black sage.
Adenostoma fasciculatum-Salvia mellifera-Rhus ovata **Association (2038)**

I.H.6.c. Chamise and black sage are sole principal shrubs with an open herbaceous understory composed mainly of nonnative species.
Adenostoma fasciculatum-Salvia mellifera **Association (2036)**

I.H.7. Scrub oak codominates with chamise (chamise and scrub oak each > 15% relative cover in the shrub layer), other shrubs in the stands are significantly less cover.
Adenostoma fasciculatum-Quercus berberidifolia **Alliance (2580)**
Adenostoma fasciculatum-Quercus berberidifolia **Association (2581)**

I.I. The overstory is dominated by redshank alone or in shared dominance with other chaparral (including chamise), deciduous, or succulent species in an open to continuous shrub canopy.

I.I.1. Redshank occurs as a dominant. If chamise is present, it occurs at trace cover.
Adenostoma sparsifolium **Alliance (2050)**

I.I.2. Redshank usually occurs with chamise as a codominant in an open to continuous shrub layer.
Adenostoma sparsifolium-Adenostoma fasciculatum **Alliance (2040)**

I.I.2.a. Hoary leaf ceanothus are characteristically present at > 1% cover.
Adenostoma sparsifolium-Adenostoma fasciculatum-Ceanothus crassifolius **Association (2042)**

<u>Group II.</u> Shrublands are dominated mainly by soft-leaved or succulent shrubs that are microphyllous or broad-leaved, and they include cactus, drought-deciduous, summer-deciduous, and/or cold-deciduous species. These are generally considered to be part of coastal sage scrub or other more soft-leaved shrub habitats. Chaparral species may be present but are

not dominant. Included are shrub willow *(Salix),* baccharis *(Baccharis),* buckwheat *(Eriogonum),* sagebrush *(Artemisia),* sage *(Salvia),* prickly pear *(Opuntia)*, bush mallow *(Malacothamnus),* poison oak *(Toxicodendron)*, California rose *(Rosa californica),* Canyon sunflower *(Venegasia carpesioides),* and so forth.

II.A. The shrub overstory is characterized by deciduous shrubs or by shrubs with scale-like leaves that are primarily found in riparian or wetland habitats.

II.A.1. Shrublands are characterized by the presence of scale broom *(Lepidospartum squamatum),* where scale broom is usually dominant but may be codominant or subdominant with other shrubs. These are generally found in rocky, occasionally flooded washes or floodplains.

***Lepidospartum squamatum* Alliance (2220)**

II.A.2. Shrublands are characterized by the dominance of mule fat alone or in shared dominance with other shrubs. An emergent and sparse tree layer of willows or other species may also be present.

***Baccharis salicifolia* Alliance (2210)**
***Baccharis salicifolia*-Riparian Association (2212)**

II.A.3. Shrublands in which a willow *(Salix*) is dominant, usually as a tall shrub or low tree. An emergent and sparse overstory tree layer may also be present.

II.A.3.a. Arroyo willow is the dominant species. (Note: May also be considered a tree, see tree key above.) It may be accompanied by mule fat *(Baccharis salicifolia),* laurel sumac *(Malosma laurina),* or other riparian shrubs.

***Salix lasiolepis* Alliance (1430)**

II.A.3.a.i. Laurel sumac is a subdominant to codominant with arroyo willow.

***Salix lasiolepis/Malosma laurina* Association (1433)**

II.A.3.a.ii. Mule fat is a characteristic subdominant or codominant with arroyo willow.

***Salix lasiolepis/Baccharis salicifolia* Association (1432)**

II.A.3.b. Narrow leaf willow *(Salix exigua)* dominates but is uncommon in small shrubby stands.

***Salix exigua* Alliance (3110)**

II.A.4. Shrublands in which California rose *(Rosa californica)* dominates the canopy, usually small narrow strips adjacent to other riparian vegetation.

***Rosa californica* Alliance (3010)**

II.A.5. Shrublands in which Mexican elderberry *(Sambucus mexicana)* is dominant in the overstory (although other shorter shrubs may be common). At times, the elderberry may take the form of a small tree.

***Sambucus mexicana* Alliance (3020)**

II.A.5.a. Mexican elderberry occurs over a mixture of herbaceous species including the native giant wild rye *(Leymus condensatus)* and other annual grasses and herbs.

***Sambucus mexicana/Leymus condensatus*/Annual Grass-Herb Association (3021)**

II.A.5.b. Mexican elderberry occurs with toyon and annual grasses and herbs in the understory.

***Sambucus mexicana-Heteromeles arbutifolia*/Annual Grass-Herb Association (3022)**

II.B. Shrublands are dominated by drought-deciduous or coastal succulent shrubs that are primarily in upland or mesic habitats.

II.B.1. Shrubland is usually characterized by the dominance of a species of encelia *(Encelia)* alone or in shared dominance with other shrubs. California sagebrush *(Artemisia californica)* occasionally may be dominant when encelia has at least 5 percent cover.

II.B.1.a. Shrubland in which California encelia *(Encelia californica)* is dominant or codominant in the canopy.

***Encelia californica* Alliance (3220)**

II.B.1.a.i. California encelia is the sole dominant or occurs with subdominant California buckwheat.

***Encelia californica* Association (3222)**

Note: Included is one phase with California buckwheat as subdominant and another phase in which California encelia is strongly dominant.

***Encelia californica-Eriogonum fasciculatum* Phase (3224)**
***Encelia californica* Phase (3222)**

II.B.1.a.ii. California sagebrush is characteristically subdominant to codominant with California encelia.

***Encelia californica-Artemisia californica* Association (3227)**

II.B.1.a.iii. Ashy buckwheat *(Eriogonum cinereum)* codominates or is subdominant with California encelia.

***Encelia californica-Eriogonum cinereum* Association (3225)**

II.B.1.a.iv. Laurel sumac and black sage regularly occur with and may codominate with California encelia.

***Encelia californica-Malosma laurina-Salvia mellifera* Association (3221)**

II.B.1.a.v. Lemonade berry *(Rhus integrifolia)* co-occurs as a subdominant to California encelia.

***Encelia californica-Rhus integrifolia* Association (3226)**

II.B.2. Shrubland with a succulent coastal prickly pear *(Opuntia oricola* or *littoralis)* or cholla *(Opuntia prolifera)* is dominant.

II.B.2.a. Coast prickly pear *(Opuntia littoralis)* is dominant or codominant with coastal sage scrub species and other cactus species.

***Opuntia littoralis* Alliance (2410)**

II.B.2.a.i. A mixture of *Opuntia* species (*littoralis, oricola,* and/or *prolifera*) may be present along with other coastal sage scrub species (*Eriogonum* spp., *Encelia californica, Artemisia californica,* etc.).

***Opuntia* spp.-Mixed Coastal Sage Scrub Association (2412)**

II.B.3. Shrubland in which giant coreopsis *(Coreopsis gigantea) is* dominant or codominant in the shrub overstory.

***Coreopsis gigantea* Alliance (3340)**

II.B.3.a. Giant coreopsis is codominant to dominant with California sagebrush and ashy buckwheat. Generally found on sea bluffs and steep slopes within one kilometer of the ocean but may extend a few kilometers inland when directly adjacent to the Conejo Plain.

***Coreopsis gigantea-Artemisia californica-Eriogonum cinereum* Association (3345)**

II.B.3.b. Giant coreopsis dominates or codominates with dune goldenbush and California encelia. Usually on sandy soils of dunes or slopes adjacent to the ocean, mostly localized around Point Dume.

***Coreopsis gigantea-Ericameria ericoides-Encelia californica* Association (3342)**

II.B.4. Shrubland in which California sagebrush *(Artemisia)* is dominant or codominant with white sage, black sage, California buckwheat, or laurel sumac in the canopy. The shrub canopy is sometimes over a higher cover of annual or perennial herbs such as bromes *(Bromus)*, cryptantha *(Cryptantha)*, stork's bill *(Erodium),* etc.

II.B.4.a. California sagebrush is codominant with California buckwheat and sometimes also with laurel sumac.

***Artemisia californica-Eriogonum fasciculatum* Alliance (3370)**

II.B.4.a.i. California sagebrush and California buckwheat usually codominate in the canopy.

***Artemisia californica-Eriogonum fasciculatum*/Annual Grass-Herb Association (3371)**

II.B.4.a.ii. California buckwheat and purple sage occur as subdominants to codominants with California sagebrush.

***Artemisia californica-Eriogonum fasciculatum-Salvia leucophylla* Association (3372)**

II.B.4.a.iii. California buckwheat is usually codominant with California sagebrush, while black sage is subdominant to codominant.

***Artemisia californica-Eriogonum fasciculatum-Salvia mellifera* Association (3373)**

II.B.4.b. California sagebrush is codominant with purple sage, and sometimes other shrubs may also be codominant.

***Salvia leucophylla* Alliance (3310)**

II.B.4.b.i. California sagebrush and purple sage are the sole dominants in the shrub canopy.

***Salvia leucophylla-Artemisia californica* Association (3391)**

Note: Included is a phase with giant wild rye at moderate cover and a phase in which the nominate species are the only species of significant cover.

***Salvia leucophylla-Artemisia californica/Leymus condensatus* Phase (3393)**
***Salvia leucophylla- Artemisia californica* Phase (3391)**

II.B.4.b.ii. California sagebrush and purple sage codominate, while ashy buckwheat is usually subdominant and *Nassella* sp. is characteristic of the herb layer.

***Salvia leucophylla-Artemisia californica-Eriogonum cinereum/Nassella* sp. Association (3396)**

Note: Included are the following three phases: one of which has ashy buckwheat along with the codominants, and two have the following shrub species:

***Salvia leucophylla-Artemisia californica-Malosma laurina/Nassella* sp. Phase (3395)**
***Salvia leucophylla-Artemisia californica-Mimulus aurantiacus* Phase (3392)**
***Salvia leucophylla- Artemisia californica-Eriogonum cinereum/Nassella* sp. Phase (3396)**

II.B.4.c. California sagebrush is the sole dominant species in the canopy, or it is sometimes codominant with laurel sumac, ashy buckwheat, or bush monkey flower. A higher cover of annual or perennial herbs such as bromes *(Bromus)* may be present.

***Artemisia californica* Alliance (3210)**

II.B.4.c.i. California sagebrush is the sole dominant species in the shrub canopy, stands may be open to dense with a sparse to dense understory of herbaceous species.

***Artemisia californica* Association (8213)**

Note: This complex association includes three phases that may be distinguished by the additional species or species groups in the epithets. In the two shrub phases, the associated species are characteristic but relatively low in cover.

***Artemisia californica*/Annual Grass-Herb Phase (8213)**
***Artemisia californica-Salvia leucophylla* Phase (3211)**
***Artemisia californica-Malosma laurina* Phase (3219)**

II.B.4.c.ii. Giant wild rye is a conspicuous understory species (may be as tall as California sagebrush) while California sagebrush is the main cover in the shrub overstory.

***Artemisia californica/Leymus condensatus* Association (3216)**

II.B.4.c.iii. Ashy buckwheat is a subdominant to codominant with California sagebrush. Bush monkey flower and the understory grass *Melica imperfecta* may be present.

***Artemisia californica-Eriogonum cinereum* Association (3214)**

Note: This complex association includes a phase with just the two nominate species as the major species and a phase where bush monkey flower and *Melica imperfecta* are subdominant species.

***Artemisia californica-Eriogonum cinereum-Mimulus aurantiacus/Melica imperfecta* Phase (3218)**
***Artemisia californica-Eriogonum cinereum* Phase (3214)**

II.B.4.c.iv. Bush monkey flower occurs as the principle codominant or subdominant with California sagebrush. If ashy buckwheat is present, it is at trace cover only.

***Artemisia californica-Mimulus aurantiacus* Association (8214)**

II.B.5. Shrubland in which a sage *(Salvia)* species is dominant in the canopy or codominant with California buckwheat or brittlebush.

II.B.5.a. White sage is present in the canopy, usually subdominant to codominant with California buckwheat. Other shrubs may be present at relatively low cover such as California sagebrush, laurel sumac, etc.

***Eriogonum fasciculatum-Salvia apiana* Alliance,**
***E. fasciculatum-S. apiana* Association (3410)**

II.B.5.b. Black sage is usually dominant in the shrub canopy but may codominate with California sagebrush, deerweed *(Lotus scoparius),* sugar bush *(Rhus ovata),* or ashy buckwheat

***Salvia mellifera* Alliance (3320)**

II.B.5.b.i. Black sage is dominant in the shrub overstory but may occur with subdominant chamise, bush mallow, or California buckwheat.

***Salvia mellifera* Association (3324)**

Note: This complex association includes a pure phase where black sage is strongly dominant, a phase in which chamise occurs as a low-cover subdominant, a postfire phase with bush mallow, and a phase with low cover of California buckwheat.

***Salvia mellifera* Phase (3324)**
***Salvia mellifera-Adenostoma fasciculatum* Phase (3329)**
***Salvia mellifera-Malacothamnus fasciculatus* Phase (3322)**
***Salvia mellifera-Eriogonum fasciculatum* Phase (3321)**

II.B.5.b.ii. Laurel sumac is subdominant to codominant in the shrub overstory, while stands may also include low cover of lemonade berry and California sagebrush.

***Salvia mellifera-Malosma laurina* Association (8324)**

Note: This complex association has been divided into two phases: one in which the nominate species alone prevail and the other based on the low cover of the characteristically associated lemonade berry.

Salvia mellifera-Malosma laurina* Phase *(8324)
***Salvia mellifera-Artemisia californica-Rhus integrifolia* Phase (8322)**

II.B.5.b.iii. Sugar bush is subdominant to codominant in the shrub overstory.

***Salvia mellifera-Rhus ovata* Association (8325)**

II.B.5.b.iv. Ashy buckwheat occurs as a subdominant to codominant with black sage.

***Salvia mellifera-Eriogonum cinereum* Association (3323)**

II.B.5.b.v. California sagebrush is subdominant to codominant with black sage; stands may include subdominant purple sage.

***Salvia mellifera-Artemisia californica* Association (8321/3421)**

Note: This association includes one phase where purple sage occurs as a subdominant.

***Salvia mellifera-Artemisia californica-Salvia leucophylla* Phase (8323)**

II.B.5.c. Black sage usually occurs as codominant with chamise in an open to continuous shrub overstory.

***Adenostoma fasciculatum-Salvia mellifera* Alliance (2030)**

(For associations in this alliance, see heading I.H.6. in class B, group I [chaparral] of the shrub key above.)

II.B.5.d. Purple sage is the dominant shrub or may be codominant with ashy buckwheat.

***Salvia leucophylla* Alliance (3310)**

II.B.5.d.i. Purple sage is dominant in the shrub layer but may be accompanied by lower cover of several other species including ashy buckwheat, California sagebrush, bush mallow, or understory species of native and nonnative grasses and herbs.

***Salvia leucophylla* Association (3316)**

Note: This complex association includes the following three phases in which other grasses and shrubs may be present as subdominants and the last phase in which only purple sage is significant in the stands.

***Salvia leucophylla/Leymus condensatus* Phase (3319)**
***Salvia leucophylla/Nassella* spp. Phase (3311)**
***Salvia leucophylla-Artemisia californica-Malacothamnus fasciculatus* Phase (8311)**
***Salvia leucophylla* Phase (3315)**

II.B.5.d.ii. Ashy buckwheat occurs as a subdominant or codominant with purple sage, usually in an open to intermittent canopy with annual species in the understory.

***Salvia leucophylla-Eriogonum cinereum*/Annual Grass-Herb Association (3312)**

II.B.5.d.iii. California sagebrush occurs as a codominant with purple sage.

***Salvia leucophylla* Alliance, *Salvia leucophylla-Artemisia californica* Associations**

(For associations in this alliance, see heading II.B.4.b. in class B, group II [coastal sage scrub] of the shrub key above.)

II.B.6. Shrubland in which a buckwheat *(Eriogonum)* species is dominant in the canopy or is codominant with black sage, laurel sumac, bush mallow, or white sage. The shrub canopy is sometimes over a higher

cover of annual or perennial herbs such as bromes *(Bromus),* cryptantha *(Cryptantha),* stork's bill *(Erodium),* wild oats *(Avena),* etc.

II.B.6.a. California buckwheat is dominant with other shrubs in the canopy.

***Eriogonum fasciculatum* Alliance (3240)**

II.B.6.a.i. California buckwheat is usually the dominant shrub in the canopy, from coastal to inland sites, though sometimes this buckwheat may codominate with deerweed *(Lotus scoparius).*

***Eriogonum fasciculatum* Association (3241)**

Note: Included is a postfire/disturbance phase with deerweed subdominant to codominant and a phase in which California buckwheat is the sole dominant.

***Eriogonum fasciculatum-Lotus scoparius* Phase (3249)**
***Eriogonum fasciculatum* Phase (3241)**

II.B.6.a.ii. California buckwheat is dominant, and black sage and laurel sumac occur as subdominants.

***Eriogonum fasciculatum-Salvia mellifera-Malosma laurina* Association (3248)**

II.B.6.b. Ashy buckwheat occurs as the dominant low shrub but may be mixed with lower cover of other shrubs such as bush mallow *(Malacothamnus fasciculatus).*

***Eriogonum cinereum* Alliance (3250)**

II.B.6.b.i. Ashy buckwheat dominates with a variable cover of annual and perennial herbs and grasses.

***Eriogonum cinereum* Association (3257)**

Note: Included is the postfire phase and a phase in which ashy buckwheat is the strong dominant.

***Eriogonum cinereum-Malacothamnus fasciculatus/Leymus condensatus* Phase (3259)**
***Eriogonum cinereum* Phase (3257)**

II.B.7. Successional shrublands in which short-lived subshrubs or shrubs of deerweed *(Lotus scoparius),* bush poppy *(Dendromecon rigida),* or bush mallow *(Malacothamnus fasciculatus)* dominate following disturbance, particularly fire. The shrub canopy is sometimes over a higher cover of annual or perennial herbs such as bromes *(Bromus),*

common sand aster *(Lessingia filaginifolia),* needlegrass *(Nassella)*, stork's bill, wild oats, etc.

II.B.7.a. Deerweed *(Lotus scoparius)* is the dominant subshrub species in the canopy.

***Lotus scoparius* Alliance,**
***Lotus scoparius* Association (3270)**

Note: Included are the following two phases:
***Lotus scoparius-Artemisia californica*/Annual Grass-Herb Phase (3273)**
***Lotus scoparius-Malacothamnus fasciculatus-Adenostoma fasciculatum-Salvia mellifera* Phase (3272)**

II.B.7.b. Bush mallow *(Malacothamnus fasciculatus)* is the dominant or codominant shrub species in the canopy. It may be associated with a variety of chaparral or coastal scrub species, which may be subdominant to codominant. These stands typically arise following fire events and do not persist for more than a decade or so.

***Malacothamnus fasciculatus* Alliance (3280)**

II.B.7.b.i. Stands strongly dominated by bush mallow with no other significant cover by shrub species.

***Malacothamnus fasciculatus* Association (3287)**

II.B.7.b.ii. Bush mallow associated with subdominant or codominant greenbark ceanothus.

***Malacothamnus fasciculatus-Ceanothus spinosus* Association (3289)**

II.B.7.b.iii. Bush mallow associated with subdominant or codominant big pod ceanothus.

***Malacothamnus fasciculatus-Ceanothus megacarpus* Association (3288)**

II.B.7.b.iv. Bush mallow is associated with subdominant laurel sumac.

***Malacothamnus fasciculatus-Malosma laurina* Association (3286)**

II.B.7.b.v. Bush mallow is associated with subdominant to codominant purple sage and often with subdominant California sagebrush.

Malacothamnus fasciculatus-Salvia leucophylla **Association (3281)**

II.B.7.b.vi. Bush mallow associated with subdominant to codominant black sage.

Malacothamnus fasciculatus-Salvia mellifera **Association (3282)**

II.B.7.c. Bush poppy dominates, usually following chaparral burns (This may also be keyed in chaparral/sclerophyllous shrubland key [Group 1 A of shrub key].)

Dendromecon rigida **Alliance,**
Dendromecon rigida **Association (3350)**

II.B.8. Shrub canopy dominated by the largely locally introduced quail bush *(Atriplex lentiformis),* usually along the coastal strip near highways.

Atriplex lentiformis **Alliance (2330)**

II.B.9. Shrub canopy dominated by the low facultatively drought-deciduous bush monkey flower.

Mimulus aurantiacus **Alliance (2170)**

II.B.9.a. Bush monkey flower is dominant and often has regularly spaced large shrubs of laurel sumac.

Mimulus aurantiacus-Malosma laurina **Association (2172)**

Note: This complex association includes a phase with purple sage as subdominant with laurel sumac as well as a phase in which only the nominate species prevail in the shrub layer.

Mimulus aurantiacus-Malosma laurina-Salvia leucophylla **Phase (2172)**
Mimulus aurantiacus-Malosma laurina **Phase (2172)**

II.C. Shrublands are typically uplands, dominated by cold-deciduous or thin broad-leaved species of mesic situations.

II.C.1. Poison oak *(Toxicodendron diversilobum)* is dominant in the shrub canopy, while a variety of other shrubs and herbs may also occur at lower cover.

Toxicodendron diversilobum **Alliance (3330)**

II.C.1.a. California sagebrush and giant wild rye mix as subdominants with poison oak in these stands.

***Toxicodendron diversilobum-Artemisia californica/Leymus condensatus* Association (3331)**

II.C.1.b. Bush monkey flower is the subdominant shrub species in the canopy.

***Toxicodendron diversilobum-Mimulus aurantiacus* Association (3332)**

II.C.2. Mexican elderberry *(Sambucus mexicana)* is the dominant shrub species in the canopy, although other species such as *Salvia leucophylla, Artemisia californica*, and *Malosma laurina* may be present. At times, the elderberry may take the form of a small tree.

***Sambucus mexicana* Alliance (3020)**

II.C.2.a. Elderberry is dominant or codominant with toyon present or conspicuous.

***Sambucus mexicana-Heteromeles arbutifolia*/Annual Grass-Herb Association (3022)**

II.C.2.b. Elderberry is the dominant shrub species over the perennial giant wild rye and other annual herbs and grasses.

***Sambucus mexicana-Leymus condensatus*/Annual Grass-Herb Association (3021)**

II.C.3. Canyon sunflower, a leafy shrub of mesic slopes, conspicuous after fire, is dominant.

***Venegasia carpesioides* Alliance (4750)**

<u>Group III.</u> Vegetation dominated by microphyllous evergreen shrubs including coyote brush *(Baccharis pilularis),* cut-leaved goldenbush *(Hazardia squarrosa),* and broom *(Spartium junceum).*

III.A. Coyote brush is dominant, often with shrubs of coastal sage, such as *Artemisia californica* and *Salvia leucophylla*, as subordinates. Sometimes coyote brush is codominant, usually in disturbed areas such as old fields, road banks, and stream and ravine borders.

***Baccharis pilularis* Alliance (2310)**

III.A.1. Coyote brush dominates over a mixture of native and nonnative annual grasses and herbs.

***Baccharis pilularis*/Annual Grass-Herb Association (2311)**

III.A.2. Coyote brush dominates with California sagebrush as a subdominant. Purple sage and laurel sumac may be present.

***Baccharis pilularis-Artemisia californica* Association (2313)**

Note: Included are three phases in which one has both California sagebrush and purple sage occurring as subdominants, one has both California sagebrush and laurel sumac as subdominants, and one in which only sagebrush and coyote bush occur.

***Baccharis pilularis-Artemisia californica-Salvia leucophylla* Phase (2315)**
***Baccharis pilularis-Malosma laurina-Artemisia californica* Phase (2314)**
***Baccharis pilularis-Artemisia californica* Phase (2313)**

III.B. Cut-leaved goldenbush is the dominant low shrub usually with a mixture of herbs and grasses plus a low cover of California sagebrush and other shrubs.

***Hazardia squarrosa* Alliance (3260)**

III.B.1. Cut-leaved goldenbush dominates with a lower cover of California sagebrush usually present. Giant wild rye and/or a mixture of annual grasses and herbs may be present.

***Hazardia squarrosa-Artemisia californica* Association (3262)**

III.B.1.a. Understory is usually strongly dominated by a mixture of annual grasses and herbs; giant wild rye is absent or inconspicuous.

***Hazardia squarrosa*/Annual Grass-Herb Phase (3261)**

III.B.1.b. Herb layer is usually with a significant cover of giant wild rye.

***Hazardia squarrosa-Artemisia californica/Leymus condensatus* Phase (3262)**

III.B.2. Cut-leaved goldenbush dominates with open or intermediate cover over a herbaceous layer characterized by the native grass *Nassella pulchra* and the native annual herb *Hemizonia fasciculate*.

***Hazardia squarrosa/Nassella pulchra-Hemizonia fasciculata* Association (3263)**

III.C. The nonnative Spanish broom dominates stands usually closely associated with road cuts in the Santa Monica Mountains.

***Spartium junceum* Alliance (9542)**

Class C. Herbaceous Vegetation

Group I. Vegetation is dominated by mainly freshwater wetland forb species including cattail *(Typha),* rush *(Juncus),* sedge *(Carex),* spike rush *(Eleocharis),* and giant reed grass *(Arundo)* species. Woody species cover < 2% of the ground surface.

I.A. Stands are dominated with > 30% absolute cover by tall (generally > 1 m) wetland grasses and graminoids including cattails *(Typha)*, bulrushes and tules *(Scirpus),* and reeds *(Arundo donax).*

I.A.1. Vegetation of common bulrush *(S. acutus)* and/or California bulrush *(S. californicus)* provides the main cover in the herbaceous canopy.
***Scirpus acutus-Scirpus californicus* Alliance (4410)**

I.A.2. Cattails (*Typha* spp.) are dominant, usually in standing fresh or brackish water.
***Typha* spp. Alliance (4420)**

I.A.3. Dense stands are dominated by giant reed *(Arundo donax),* generally small and locally distributed along streams and creeks.
***Arundo donax* Alliance (4310)**

I.B. Stands are dominated by grasses and graminoids that are generally between 0.1–1 m tall including rushes *(Juncus)* and sedges *(Carex).*

I.B.1. A rush species, specifically common rush *(Juncus effusus),* is the sole dominant in the herb overstory.
***Juncus effusus* Alliance (4330)**

I.C. Stands are dominated (> 30% relative cover) by annual or perennial forbs.

I.C.1. Vegetation is dominated > 30% relative cover by the perennial noxious forb perennial pepperweed *(Lepidium latifolium),* occasional along creeks and valley bottoms, especially in the Malibu Creek watershed.
***Lepidium latifolium* Alliance (4780)**

Group II. Vegetation dominated mainly by upland and mesic herbaceous species including native and exotic grasses, forbs, and cryptogrammic species. If woody species are present, they cover < 10% of the ground surface.

II.A. Vegetation is dominated by a mixture of native perennial grasses and annuals, with the native grasses usually making up > 10% relative cover of the herbaceous layer.

II.A.1. Native grass component is usually mainly purple needlegrass *(Nassella pulchra),* and the annual component is a mixture of grasses and forbs.

***Nassella pulchra* Alliance (4020)**

II.A.1.a. Purple needlegrass co-occurs with < 10% cover of the low microphyllous shrub cut-leaved goldenbush.

***Nassella pulchra-Hazardia squarrosa* Association (4021)**

II.A.2. Native grass component is dominated by foothill needlegrass *(Nassella lepida)* alone or in shared dominance with other native and nonnative grasses and forbs. Stands are uncommon and may include emergent shrubs of the coastal sage scrub formation.

***Nassella lepida* Alliance (4090)**

II.A.3. Stands are usually on slopes associated with scrub or woodland vegetation dominated by the coarse, moderately tall giant wild rye.

***Leymus condensatus* Alliance (4040)**
***Leymus condensatus* Association (4041)**

II.A.4. Stands of the lowland or valley bottom species creeping wild rye *(Leymus triticoides)* are generally small and uncommon in study area.

***Leymus triticoides* Alliance (4030)**

II.B. Vegetation is dominated mainly by nonnative invasive perennial bunchgrasses.

II.B.1. Fountain grass *(Pennisetum setaceum)* occurs as the dominant species, though other species may be subdominant, usually on steep coastal bluffs or road cuts.

***Pennisetum setaceum* Alliance (4060)**

II.B.1.a. While fountain grass is dominant, native coastal shrubs such as *Coreopsis gigantea, Malosma laurina*, and *Yucca whipplei* occur as subdominants.

***Pennisetum setaceum-Coreopsis gigantea-Yucca whipplei-Malosma laurina* Association (4061)**

II.B.2. Harding grass *(Phalaris aquatica)* is dominant with at least 40–50% relative cover, usually in old low-lying pastures and bottomland grasslands.

***Phalaris aquatica* Alliance (4070)**

II.C. Grasslands or forb lands are strongly dominated by nonnative annual grasses and forbs including red brome, ripgut brome, Italian ryegrass, wild oat, star thistle, and black mustard. There may be native species, but these may be relatively low cover.

California Annual Grassland Alliance (5000/4340)

II.C.1. Ripgut brome *(Bromus diandrus)* is abundant; however, an assortment of other herbs and grasses also usually occur in the stands including native species such as sun cup (*Camissonia* spp.), common sand aster *(Lessingia filaginifolia),* etc.

***Bromus diandrus*-Mixed Herb Association (50005)**

II.C.2. Ripgut brome *(Bromus diandrus)* is abundant or codominant with nonnative oats (*Avena barbata* and/or *A. fatua*).

***Bromus diandrus-Avena* spp. Association (50007)**

II.C.3. Wild oats *(Avena fatua)* are dominant with lower cover of all other nonnative and native species.

***Avena fatua* Association (4220)**

II.C.4. Italian ryegrass *(Lolium multiflorum)* is strongly dominant with low cover of all other nonnative and native species and is often found in low-lying portions of grasslands.

***Lolium multiflorum* Association (4210)**

II.C.5. Black mustard *(Brassica nigra)* is dominant or codominant in stands made up largely of other nonnative herbs and grasses.

II.C.5.a. Black mustard is the sole dominant.

***Brassica nigra* Association (50006)**

II.C.5.b. Ripgut brome and black mustard are both important or codominant in the stands.

***Brassica nigra-Bromus diandrus* Association (50009)**

II.C.5.c. Black mustard and star thistle *(Centaurea melitensis)* are both important or codominant in the stands.

***Brassica nigra-Centaurea melitensis* Association (50008)**

II.D. Stands of vegetation dominated by medium to tall introduced perennial herbs including fennel and *Euphorbia terracina*.

II.D.1. Sweet fennel *(Foeniculum vulgare)* dominates usually weedy stands along road cuts and steep coastal slopes but also may be found in bottomlands on the edge of the Conejo Plain.

***Foeniculum vulgare* Alliance (4760)**

II.D.2. The noxious perennial weed *Euphorbia terracina* dominates fields, fire clearance areas, and roadsides along the immediate coast.

***Euphorbia terracina* Nonnative Stands (4771)**

<u>Group III.</u> Vegetation dominated mainly by relatively low perennial forbs and graminoids of coastal, more or less, saline environments including brackish and salt marshes, sea cliffs, and dunes.

III.A. Salt marsh vegetation dominated or codominated by pickleweed (*Salicornia virginica* and/or *S. subterminalis*).

***Salicornia virginica* Alliance (4520)**

III.A.1. Pickleweed *(Salicornia virginica)* form and are open to intermittent cover over mudflats with marine filamentous algae.

***Salicornia virginical*Algae Association (4528)**

III.A.2. *Salicornia virginica* mix as dominant, codominant, or subdominant with *Salicornia subterminalis*.

***Salicornia virginica-Salicornia subterminalis* Association (4525)**

III.A.3. *Salicornia virginica* is dominant with a constant presence of California sea blite, often seen near salt pans.

***Salicornia virginica-Suaeda taxifolia* (synonym *S. californica* var. *taxifolia)* Association (4525)**

III.A.4. *Salicornia virginica* codominates with *Jaumea carnosa* and perennial grass *Distichlis spicata.*

***Distichlis spicata-Salicornia virginica-Jaumea carnosa* Association (4527)**

Note: Two phases occur: one with lesser presence of pickleweed and one with greater presence of pickleweed.

***Distichlis spicata-Jaumea carnosa* Phase (4514)**
***Salicornia virginica-Jaumea carnosa-Distichlis spicata* Phase (4527)**

III.A.5. *Salicornia virginica* dominates with *Frankenia salina* as a constant associate.

III.A.5.a. *Frankenia salina* is > 1% and constant along with *Salicornia virginica.* Other species may occur as subdominants.

***Salicornia virginica-Frankenia salina* Association (45201)**

Note: Included are three phases: one with consistent presence and subdominance of *Batis maritima* with the *Frankenia salina,* one with consistent presence and subdominance of *Suaeda taxifolia* with the *Frankenia salina,* and one with *Suaeda taxifolia* higher in cover than *Frankenia salina.*

***Salicornia virginica-Frankenia salina-Batis maritima* Phase (4526)**
***Salicornia virginica-Frankenia salina-Suaeda taxifolia (*synonym *Suaeda californica)* Phase (4524)**
***Salicornia virginica-Suaeda taxifolia (*synonym *Suaeda californica)* Phase (45201)**

III.A.6. *Salicornia virginica* occurs with the nonnative black mustard, usually at the edge of the marsh in slightly elevated areas.

***Salicornia virginica-Brassica nigra* Association (4529)**

III.B. Salt marsh vegetation dominated by the perennial forb *Frankenia salina*, usually mixed with other saline forbs and grasses.

***Frankenia salina* Alliance (4550)**

III.B.1. *Frankenia salina* associates with the herbs *Limonium californicum* and *Salicornia* spp. and the native salt-tolerant grass *Monanthochloe littoralis.*

***Frankenia salina-Limonium californicum-Monanthochloe littoralis-Salicornia* spp. Association (4551)**

III.C. Salt marsh and coastal low-spreading, turf-forming salt grass is the dominant species and may have emergent low shrubs and taller perennial herbs.

***Distichlis spicata* Alliance (4510)**

III.C.1. Salt grass associates with the sand-loving, coastal dune burweed.

***Distichlis spicata-Ambrosia chamissonis* Association (4511)**

III.C.2. Salt grass associates with marsh jaumea *(Jaumea carnosa)* and pickleweed *(Salicornia virginica)*.

***Distichlis spicata-Salicornia virginica-Jaumea carnosa* Association (n/a)**

Note: Two phases occur: one with lesser presence of pickleweed and one with greater presence of pickleweed.

***Distichlis spicata-Jaumea carnosa* Phase**
***Salicornia virginica-Jaumea carnosa-Distichlis spicata* Phase**

III.D. The low spreading and invasive succulent perennial sea fig (ice plant) is strongly dominant, usually on bluffs or dunes adjacent to the ocean.

***Mesembryanthemum* spp.-*Carpobrotus* spp. SemiNatural Herbaceous Alliance (4720)**

III.D.1. *Carpobrotus edulis* (sea fig) is the dominant species.

***Carpobrotus edulis* Association (4720)**

<u>Group IV.</u> Vegetation of rocky outcrops and cliffs usually dominated by low-matted spike moss, *Selaginella bigelovii,* or widely scattered but conspicuous individuals of buckwheat with spike moss.

IV.A. Spike moss occurs as intermediate to dense mat with emergent California buckwheat and sometimes other shrubs and herbs.

***Selaginella bigelovii* Alliance (4810)**

IV.A.1. *Selaginella bigelovii* dominates the low herb layer with emergent annual and perennial herbs, grasses, and a constant presence of California buckwheat at low cover.

***Selaginella bigelovii/Eriogonum fasciculatum* Association (4811)**

Tree Overstory Vegetation Descriptions

Alnus rhombifolia-Platanus racemosa Woodland/Forest Association

White Alder-California Sycamore Woodland/Forest Association
***Alnus rhombifolia* Woodland/Forest Alliance**
White Alder Woodland/Forest Alliance

Mapping Code: 1441

Local Description

Summary:
This woodland/forest association occurs on gentle to abrupt slopes with variable aspects at elevations between 7 and 202 m. It is codominated by *Alnus rhombifolia* and *Platanus racemosa* in the tree layer, *Salix lasiolepis* and *Ceanothus spinosus* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Immediate Coast and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 7–202 m, mean 80 m
Aspect: variable
Slope: range 0–35 degrees, mean 14 degrees
Topography (micro; macro): often concave; often bottom and lower slopes
Litter Cover: range 25–80%, mean 46.7%
Small Rock Cover: range 0–30%, mean 13.6%
Large Rock Cover: range 0–28%, mean 11.6%
Bare Ground: range 7–30%, mean 15%
Parent Material: depositional or igneous
Soil Texture: sand

Vegetation Description:
Stands of *Alnus rhombifolia-Platanus racemosa* Woodland/Forest form an open to intermittent tree layer (31–55%, mean 39.7%) with conifers at 0–15 m tall and hardwoods at 5–15 m tall, a sparse to open shrub layer (1–12%, mean 6.7%) at 0–5 m tall, and a sparse to intermittent herbaceous layer (0–46%, mean 9.7%) at 0–5 m tall. Total vegetation cover is 40–75%, mean cover is 53%.

In this association, the tree layer is dominated by *Alnus rhombifolia* and *Platanus racemosa*, and *Quercus agrifolia* and *Umbellularia californica* are frequently included in this layer at lower cover. The shrub layer is sparse to open and occasionally includes *Salix lasiolepis* and *Ceanothus spinosus. Malosma laurina* and *Baccharis salicifolia* may also be present in low cover. The herbaceous layer is diverse and includes a variety of forbs and grasses such as *Piptatherum miliaceum, Cyperus* sp., *Euphorbia terracina, Rubus ursinus, Bromus diandrus, Arundo donax, Vinca major, Foeniculum vulgare, Artemisia douglasiana,* and *Brassica nigra.*

Other Noteworthy Species:
Baccharis plummerae was found in 1 of 9 surveys of this plant community, which is assumed to be the rare subspecies *B. p.* subsp. *plummerae.* Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-1-3. Global rank is G3T3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Juglans californica was found in 4 of 9 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Piptatherum miliaceum, Euphorbia terracina, Bromus diandrus, Arundo donax, Vinca major, Foeniculum vulgare, Ricinus communis, Brassica nigra, Tropaeolum majus, Hedera helix, Raphanus sativus, Conium maculatum, Rumex crispus, Centaurea melitensis, Cirsium vulgare, Malva parviflora, Melilotus albus, Nicotiana glauca, Phoenix canariensis, Rorippa nasturtium-

aquaticum, Salsola tragus, Senecio mikanioides, Spartium junceum

rap0384, rap1482, rap2168, rap2206m, rap2457rlv, rap2569, rap2605, rap2650, rap2760

Comments:
Alnus rhombifolia and *Platanus racemosa* co-occur throughout much of the mountainous and hilly parts of south coastal California. Stands in the SAMO study area are restricted to permanently flowing creeks mostly in the coastal strip.

Phases:
None

COMMON NAME	White Alder-California Sycamore Woodland/Forest Association
SYNONYM	Southern Sycamore-Alder Riparian Woodland (Holland 1996)
PHYSIOGNOMIC CLASS	Forest
PHYSIOGNOMIC SUBCLASS	Deciduous forest
PHYSIOGNOMIC GROUP	Cold-deciduous forest
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural cold-deciduous forest
FORMATION	Temporarily flooded cold-deciduous forest
ALLIANCE	*Alnus rhombifolia* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is known from the Santa Monica Mountains region and western Riverside County, though it may be found in other regions in southern California with additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This association occurs along riparian corridors of concave creek bottoms to lower slopes that are gentle to abrupt. It is known to occur near the coast in southern California (Ventura County) and inland within the peninsular range (western Riverside County) at elevations usually below 1800 m.

Vegetation Description:
Based on data from western Riverside County, the following information can augment the local description above. In the *Alnus rhombifolia-Platanus racemosa* Association, both tree species are codominant and may be regenerating in the understory. Other trees may also be

codominant, including *Quercus agrifolia* and *Salix laevigata*, and a variety of herb species may be present in this association.

Comments:
This association is likely to occur in other parts of south coastal California. To date, an analogous association has been recently described from western Riverside County, and a similar association of *Alnus rhombifolia-Platanus racemosa-Quercus chrysolepis* has been recently described from inland San Diego County. In addition, a similar association of *Alnus rhombifolia-Salix laevigata-Platanus racemosa* is described in lower montane of the southern Sierra Nevada below 1,000 m. Other than these three trees listed in this association, there is moderate to low constancy and cover of *Fraxinus latifolia*, *Quercus* spp., *Salix lasiolepis, Toxicodendron diversilobum,* and *Rubus ursinus.*

Eucalyptus Woodland/Forest Alliance

Eucalyptus Woodland/Forest Alliance

Mapping Code: 9510

Local Description

Summary:
This woodland/forest alliance occurs on gentle to steep slopes with variable aspects at low elevations between 31 and 341 m. The tree layer is open to dense, and it is mainly dominated by *Eucalyptus* spp. Both shrub and herb layers are sparse to open, and they may include *Malosma laurina* and *Heteromeles arbutifolia* as shrubs and *Hirschfeldia incana* and annual grasses.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains., Western Fog Zone, Eastern Urban, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 31–341 m, mean 202.6 m
Aspect: variable
Slope: range 2–35 degrees, mean 18.7 degrees
Topography (micro; macro): variable, though more concave; mainly bottom
Litter Cover: range 65–75%, mean 70%
Small Rock Cover: range 2–5%, mean 3%
Large Rock Cover: range 0–8%, mean 3.3%
Bare Ground: range 8–25%, mean 14.3%
Parent Material: variable sediments, though more often igneous and sedimentary
Soil Texture: no data

Vegetation Description:
Stands of the *Eucalyptus* Woodland/Forest Alliance form an open to continuous tree layer (15–67% cover, mean 40.9%) with conifers at 0–15 m tall and hardwoods at 5–50 m tall. The shrub layer is sparse to open and may occur in two different strata at (0–15%, mean 3%), with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is sparse to open (0–20%, mean 5.4%) at 0–0.5 m tall. Total vegetation cover is 28–68%, mean cover is 49.4%.

In this alliance, the tree layer is dominated by *Eucalyptus* spp. *Quercus agrifolia, Platanus racemosa,* and *Pinus* (introduced species) are occasionally included in this layer at low cover. *Eucalyptus* spp. sometimes regenerates in the understory. The shrub tree layer is open and may include *Malosma laurina* and *Heteromeles arbutifolia* at low cover. The herbaceous layer is usually simple and open, and it may include *Hirschfeldia incana* and annual grasses.

United States

States or Provinces:
CA

Environmental Description:
Stands occur in various settings, usually the result of plantings. Most stands in California are below 1,000 m in elevation and are west of the Cascade-Sierra Divide.

Vegetation Description:
Stands are strongly dominated by *Eucalyptus* spp. Coastal stands tend to develop a seminatural understory with *Toxicodendron diversilobum* and other native shade-tolerant shrubs.

Comments:
This alliance is composed of vegetation types that are dominated by species not native to the western United States. Nine species of *Eucalyptus* are included in this alliance in California; none of them are native to North America. A description can be developed in the future for this alliance should it prove useful to do so.

Juglans californica/Annual Grass-Herb Woodland/Forest Association

California Walnut/Annual Grass-Herb Woodland/Forest Association
***Juglans californica* Woodland/Forest Alliance**
California Walnut Woodland/Forest Alliance

Mapping Code: 1312

Local Description

Summary:
This woodland/forest association occurs on somewhat steep to steep slopes with variable aspects at low elevations between 119 and 461 m. It is dominated by *Juglans californica* in the tree layer and a variety of forbs and grasses in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Eastern Urban, Upper Elevation Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 119–461 m, mean 310 m
Aspect: variable
Slope: range 15–38 degrees, mean 25 degrees
Topography (micro; macro): variable but often undulating; lower to top slopes
Litter Cover: range 75–85%, mean 80%
Small Rock Cover: range 0–15%, mean 5.4%
Large Rock Cover: range 0–2%, mean 0.8%
Bare Ground: range 2–30%, mean 15%
Parent Material: often sedimentary, occasionally igneous or depositional
Soil Texture: moderately fine clay loam to fine clay

Vegetation Description:
Stands of *Juglans californica*/Annual Grass-Herb Woodland/Forest form a sparse to intermittent tree layer (5–45%, mean 21.5%) with hardwoods at 2–10 m tall, a sparse to open shrub layer (0–15%, mean 5.7%) at 0–10 m tall, and an open to intermittent herbaceous layer (12–45%, mean 30.8%) at 0–1m tall. Total vegetation cover is 37–65%, mean cover is 54.9%.

In this association, the tree layer is dominated by *Juglans californica*. *Quercus agrifolia* is occasionally included in this layer. The shrub layer is sparse to open and occasionally includes *Artemisia californica, Malosma laurina,* and *Toxicodendron diversilobum*. The herbaceous layer is diverse and includes *Brassica nigra, Leymus condensatus, Bromus* sp., *Bromus diandrus, Marah macrocarpus, Centaurea melitensis, Galium aparine, Marrubium vulgare,* and a variety of other native and nonnative species.

Other Noteworthy Species:
Juglans californica was found in 16 of 16 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Brassica nigra, Bromus diandrus, Centaurea melitensis, Galium aparine, Marrubium vulgare, Erodium, Stellaria media, Brassica, Hirschfeldia incana, Avena fatua, Avena barbata, Cirsium vulgare, Malva parviflora, Urtica urens, Bromus hordeaceus, Carduus pycnocephalus, Lactuca serriola, Nicotiana glauca

Samples Used in Description: (n = 16)
AA0108cc, AA0151cc, AA0313cc, AA0321cc, AA0612, AA0932, AA0991, rap0619, rap0621, rap0702, rap0703, rap1072, rap1506m, rap1950, rap2082, rap2608

Comments:
As a general note, cover values of *Juglans* are likely to average higher than recorded because some sampling was done during periods when the leaves of this deciduous species were largely absent. This type is often found in disturbed and urban settings.

Phases:
None

COMMON NAME California Walnut/Annual Grass-Herb Woodland/Forest Association
SYNONYM None
PHYSIOGNOMIC CLASS Woodland

PHYSIOGNOMIC SUBCLASS	Deciduous woodland
PHYSIOGNOMIC GROUP	Cold-deciduous woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural cold-deciduous woodland
FORMATION	Cold-deciduous woodland
ALLIANCE	*Juglans californica* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This association is likely to be restricted to the Santa Monica Mountains and other parts of the western Los Angeles Basin of California. Higher-quality stands have a relatively high native to nonnative understory species component.

Juglans californica/Artemisia californica/Leymus condensatus Woodland/Forest Association

California Walnut/California Sagebrush/Giant Wild Rye Woodland/Forest Association
***Juglans californica* Woodland/Forest Alliance**
California Walnut Woodland/Forest Alliance

Mapping Code: 1317

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes with variable aspects at low elevations between 41 and 500 m. It is dominated by *Juglans californica* in the tree layer, *Artemisia californica* in the understory shrub layer, and *Leymus condensatus* in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 41–500 m, mean 311.5 m
Aspect: variable, but often northeast or northwest
Slope: range 2–42 degrees, mean 29.5 degrees
Topography (micro; macro): variable but often undulating or convex; lower to top slopes
Litter Cover: range 2–40%, mean 21%
Small Rock Cover: range 15–20%, mean 16%
Large Rock Cover: range 0–8%, mean 2.2%
Bare Ground: range 20–40%, mean 29%
Parent Material: often sedimentary, occasionally depositional or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Juglans californica/Artemisia californica/Leymus condensatus* Woodland/Forest form a sparse to intermittent tree layer (5–36%, mean 20.3%) with hardwoods at 2–10 m tall, a sparse to intermittent shrub layer (5–47%, mean 28.2%) at 0–5 m tall, and a sparse to open herbaceous layer (0–30%, mean 7.5%) at 0–2 m tall. Total vegetation cover is 40–70%, mean cover is 53.5%.

In this association, the tree layer is dominated by *Juglans californica*. *Quercus agrifolia* and *Platanus racemosa* are occasionally included in this layer. The shrub layer is sparse to intermittent and often includes *Artemisia californica*. Frequently, *Salvia leucophylla*, *Toxicodendron diversilobum,* and *Malosma laurina* are also included. A variety of other shrubs is also present in lower cover. The herbaceous layer is diverse and is dominated by *Leymus condensatus.* Other herbs include *Centaurea melitensis, Hirschfeldia incana,* and a variety of native and nonnative grasses and forbs.

Juglans californica/Ceanothus spinosus Woodland/Forest Association

California Walnut/Greenbark Ceanothus Woodland/Forest Association
***Juglans californica* Woodland/Forest Alliance**
California Walnut Woodland/Forest Alliance

Mapping Code: 1315

Local Description

Summary:
This woodland/forest association occurs on somewhat steep to steep slopes, usually on northeast aspects, at low elevations between 193 and 616 m. It is dominated by *Juglans californica* in the tree layer, *Ceanothus spinosus* in the understory shrub layer, and a mixture of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 193–616 m, mean 407.5 m
Aspect: variable but often northeast
Slope: range 15–42 degrees, mean 29.8 degrees
Topography (micro; macro): variable but often undulating; bottom to upper slopes
Litter Cover: no data
Small Rock Cover: range 5–35%, mean 16.7%
Large Rock Cover: range 0–2%, mean 1%
Bare Ground: range 13–55%, mean 27.7%
Parent Material: variable but more often sedimentary
Soil Texture: medium loam

Vegetation Description:
Stands of *Juglans californica/Ceanothus spinosus* Woodland/Forest form a sparse to intermittent tree layer (7–33%, mean 15.4%) with hardwoods at 2–10 m tall, a sparse to intermittent shrub layer (9–50%, mean 37.2%) at 0–5 m tall, and a sparse to open herbaceous layer (0–12%, mean 2.2%) at 0–2 m tall. Total vegetation cover is 38–66%, mean cover is 54.6%.

In this association, the tree layer is dominated by *Juglans californica*. *Quercus agrifolia* is frequently included in this layer. The shrub layer is sparse to intermittent and is dominated by *Ceanothus spinosus*, though *Heteromeles arbutifolia* is frequently present in lower cover. Occasionally, *Rhus ovata*, *Malosma laurina, Mimulus aurantiacus, Ceanothus megacarpus,* and *Sambucus mexicana* are also included. The herbaceous layer is simple and composed of a mixture of grass and forb species in low cover such as *Leymus condensatus*, *Marah macrocarpus,* and *Melica imperfecta.*

Nicotiana glauca, Senecio mikanioides, Bromus diandrus, Bromus hordeaceus, Avena, Euphorbia terracina, Foeniculum vulgare

Samples Used in Description: (n = 18)
AA0472cc, AA0601, AA0608, AA0671, AA1142, AA1168, AA1206, rap0476, rap0491, rap1174m, rap1742, rap2475, rap2516, rap2576, rap2590m, rap2626, rap2639, rap2925

Comments:
This California walnut association typically occurs adjacent to other north-facing slope scrubs and is probably more similar to a chaparral type with emergent walnut. It has a small proportion of *Quercus agrifolia* associated with it about half the time. Taken together, either understory or overstory *Juglans californica* occurs at 100% frequency, and cover values of *Juglans* are likely to average higher than recorded because some sampling was done during periods when the leaves of this deciduous species were largely absent.

Phases:
None

Juglans californica/Heteromeles arbutifolia Woodland/Forest Association

California Walnut/Toyon Woodland/Forest Association
***Juglans californica* Woodland/Forest Alliance**
California Walnut Woodland/Forest Alliance

Mapping Code: 6312

Local Description

Summary:
This woodland/forest association occurs on somewhat steep to steep slopes with variable aspects (though often northeast facing) at elevations between 237 and 514 m. It is dominated by *Juglans californica* in the tree layer and *Heteromeles arbutifolia* in the understory shrub layer. A variety of grass and forbs occurs in the herbaceous layer.

Distribution:
This association is sampled in the Eastern Urban, Upper Elevation Santa Monica Mountains, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 237–514 m, mean 327.1 m
Aspect: variable, but often northeast or northwest
Slope: range 15–40 degrees, mean 28 degrees
Topography (micro; macro): variable but often undulating; bottom to top slopes
Litter Cover: 75%
Small Rock Cover: range 5–15%, mean 6.8%
Large Rock Cover: range 0–2%, mean 0.2%
Bare Ground: range 5–25%, mean 16.3%
Parent Material: more often sedimentary, occasionally igneous or metamorphic
Soil Texture: moderately fine silty clay loam to fine clay but more often moderately fine clay loam

Vegetation Description:
Stands of *Juglans californica/Heteromeles arbutifolia* Woodland/Forest form a sparse to intermittent tree layer (6–58%, mean 21.6%) with conifers at 0–15 m tall and hardwoods at 2–15 m tall, a sparse to intermittent shrub layer (0–40%, mean 24.4%) at 0–10 m tall, and a sparse to intermittent herbaceous layer (0–37%, mean 8.2%) at 0–1 m tall. Total vegetation cover is 25–68%, mean cover is 52.5%.

In this association, the tree layer is dominated by *Juglans californica. Quercus agrifolia* is frequently included in this layer. The shrub layer is sparse to intermittent and is dominated by *Heteromeles arbutifolia* although *Rhus ovata* and *Malosma laurina* are frequently present. Occasionally, *Ceanothus spinosus, Quercus berberidifolia, Sambucus mexicana, Salvia mellifera,* and *Artemisia californica* are also included. The herbaceous layer is diverse and includes a variety of grasses and forbs in low cover such as *Brassica nigra, Marah macrocarpus, Leymus condensatus,* and *Marrubium vulgare.*

Comments:
Compared to the *Juglans californica/Ceanothus spinosus* Association, this association has a higher cover and constancy of *Quercus agrifolia* and *Heteromeles arbutifolia*. Both of these associations tend to occur on northeast-facing exposures and on disturbed sights. *H. arbutifolia* is often as tall as the walnut.

As a general note, cover values of *Juglans* are likely to average higher than recorded because some sampling was done during periods when the leaves of this deciduous species were largely absent.

Phases:
None

Juglans californica/Malosma laurina Woodland/Forest Association

California Walnut/Laurel Sumac Woodland/Forest Association
***Juglans californica* Woodland/Forest Alliance**
California Walnut Woodland/Forest Alliance

Mapping Code: 1314

Local Description

Summary:
This woodland/forest association occurs on gentle to very steep slopes on all aspects at low elevations between 20 and 460 m. It is dominated by *Juglans californica* in the tree layer, *Malosma laurina* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Immediate Coast, Upper Elevation Santa Monica Mountains, Eastern Urban, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 20–460 m, mean 252.7 m
Aspect: all aspects but often northeast
Slope: range 2–50 degrees, mean 20.7 degrees
Topography (micro; macro): variable; bottom to top slopes
Litter Cover: 55%
Small Rock Cover: range 5–30%, mean 19.3%
Large Rock Cover: range 0–2%, mean 1%
Bare Ground: range 12–30%, mean 21.8%
Parent Material: more often sedimentary, occasionally igneous or depositional
Soil Texture: moderately fine sandy clay loam to fine clay

Vegetation Description:
Stands of *Juglans californica/Malosma laurina* Woodland/Forest form a sparse to intermittent tree layer (4–40%, mean 14.3%) with hardwoods at 0–15 m tall, an open to intermittent shrub layer (10–55%, mean 27.8%) at 0.5–5 m tall, and a sparse to intermittent herbaceous layer (0–41%, mean 10.9%) at 0–1 m tall. Total vegetation cover is 40–62%, mean cover is 51.2%.

In this association, the tree layer is dominated by *Juglans californica*. *Quercus agrifolia* and *Platanus racemosa* are occasionally found in lower cover in this layer. The open to intermittent shrub layer is dominated by *Malosma laurina.* Frequently, *Artemisia californica, Heteromeles arbutifolia,* and *Malacothamnus fasciculatus* are found in lower cover in this layer. A variety of other shrubs is also included in this layer. The herbaceous layer is diverse and includes *Leymus condensatus, Bromus* sp.*, Avena* sp.*, Erodium* sp., *Medicago polymorpha,* and *Marah macrocarpus.*

Other Noteworthy Species:
Juglans californica was found in 12 of 12 surveys of this plant community. Regionally, the park considers this species as RarE. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Avena, Erodium, Medicago polymorpha, Bromus diandrus, Bromus hordeaceus, Bromus madritensis, Centaurea melitensis, Nicotiana glauca, Brassica, Brassica nigra, Pennisetum setaceum, Hirschfeldia incana, Euphorbia terracina, Nerium oleander, Stellaria media, Marrubium vulgare, Melilotus indicus, Ricinus communis, Schinus molle, Silybum marianum

AA0015cc, AA0183cc, rap0029, rap0170, rap0617, rap0719, rap1079, rap1141, rap1843, rap2081, rap2655, rap2767

Comments:
This association is widespread in the Santa Monica Mountains. It tends to occur on a wider range of aspects than most other associations and is the only association in this alliance that has a significant cover of *Malosma laurina.*

As a general note, cover values of *Juglans* are likely to average higher than recorded because some sampling was done during periods when the leaves of this deciduous species were largely absent.

Phases:
None

Platanus racemosa South Coast Intermittent Stream Woodland/Forest Association

California Sycamore South Coast Intermittent Stream Woodland/Forest Association
***Platanus racemosa* Woodland/Forest Alliance**
California Sycamore Woodland/Forest Alliance

Mapping Code: 6451

Local Description

Summary:
This woodland/forest association occurs on gentle to somewhat steep slopes with variable aspects at low elevations between 134 and 460 m. It is dominated by *Platanus racemosa* in the tree layer. The shrub and herbaceous layers are open.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Dry Inland, Eastern Urban, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 134–460 m, mean 325 m
Aspect: variable
Slope: range 2–15 degrees, mean 10.5 degrees
Topography (micro; macro): concave or flat; bottom to mid slopes
Litter Cover: 55%
Small Rock Cover: range 3–8%, mean 5.5%
Large Rock Cover: range 2–5%, mean 3.5%
Bare Ground: range 2–15%, mean 8.5%
Parent Material: variable
Soil Texture: moderately fine silty clay loam

Vegetation Description:
Stands of *Platanus racemosa* Woodland/Forest form an open to intermittent tree layer (15–59%, mean 37.3%) with hardwoods at 5–15 m tall, a sparse to open shrub layer (0–13%, mean 6.8%) at 0–5 m tall, and a sparse herbaceous layer (0–8%, mean 2.2%) at 0–1 m tall. Total vegetation cover is 28–60%, mean cover is 46.5%.

In this association, the tree layer is dominated by *Platanus racemosa*. *Juglans californica* is occasionally included in this layer. The shrub layer is sparse to open and includes *Toxicodendron diversilobum, Ceanothus spinosus,* and *Heteromeles arbutifolia* in low cover. Various other shrubs also contribute to low cover. The herbaceous layer is simple and most often includes *Leymus condensatus.* Other herbs occasionally include *Artemisia douglasiana* and *Rubus ursinus*.

***Platanus racemosa* South Coast Intermittent Stream Association**

Platanus racemosa/Annual Grass-Herb Woodland/Forest Association

California Sycamore/Annual Grass-Herb Woodland/Forest Association
***Platanus racemosa* Woodland/Forest Alliance**
California Sycamore Woodland/Forest Alliance

Mapping Code: 1456

Local Description

Summary:
This woodland/forest association occurs on flat to gentle slopes at low elevations between 34 and 140 m. It consists of *Platanus racemosa* dominating in the tree layer and *Bromus diandrus* dominating in the herbaceous layer.

Distribution:
This association is sampled in the Western Fog Zone and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 34–140 m, mean 77 m
Aspect: flat
Slope: range 0–2 degrees, mean 1.2 degrees
Topography (micro; macro): flat; bottom to lower slopes
Litter Cover: range 35–35%, mean 35%
Small Rock Cover: range 0–17%, mean 7.3%
Large Rock Cover: range 0–3%, mean 0.8%
Bare Ground: range 4–30%, mean 14.8%
Parent Material: depositional
Soil Texture: silt to fine sandy clay

Vegetation Description:
Stands of *Platanus racemosa*/Annual Grass-Herb Woodland/Forest form a sparse to open tree layer (6–22%, mean 13.2%) with conifers at 0–15 m tall and hardwoods at 10–20 m tall, a sparse shrub layer (0–2%, mean 0.4%) at 0–5 m tall, and an open to intermittent herbaceous layer (17–64%, mean 42.8%) at 0–1 m tall. Total vegetation cover is 38–68%, mean cover is 53.2%.

In this association, the tree layer is dominated by *Platanus racemosa*. The shrub layer is sparse and often includes *Malacothamnus fasciculatus*, while *Baccharis pilularis, Baccharis salicifolia, Salix lasiolepis,* and *Spartium junceum* are occasionally included at very low cover. The herbaceous layer is diverse yet often dominated by nonnative species such as *Bromus diandrus, Marrubium vulgare, Brassica nigra,* and *Cirsium vulgare.* Other herbs occasionally occurring at low cover include *Ambrosia* sp., *Arundo donax, Piptatherum miliaceum, Foeniculum vulgare,* and *Cynodon dactylon.*

Platanus racemosa-Quercus agrifolia South Coast Woodland/Forest Association

California Sycamore-Coast Live Oak South Coast Woodland/Forest Association
***Platanus racemosa* Woodland/Forest Alliance**
California Sycamore Woodland/Forest Alliance

Mapping Code: 1452

Local Description

Summary:
This woodland/forest association occurs on moderately steep to steep slopes with variable aspects at low elevations between 166 and 480 m. It is codominated by *Platanus racemosa* and *Quercus agrifolia* in the tree layer, usually as a woodland. *Heteromeles arbutifolia* is characteristically present at low cover in the understory shrub layer, and a variety of grasses and forbs is in the herbaceous layer.

Distribution:
This association is sampled in the Eastern Urban, Lower Elevation Inland Santa Monica Mountains, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 166–480 m, mean 280 m
Aspect: variable
Slope: range 10–35 degrees, mean 16.9 degrees
Topography (micro; macro): often concave; bottom to mid slopes
Litter Cover: 75%
Small Rock Cover: range 2–5%, mean 3.5%
Large Rock Cover: range 1–2%, mean 1.5%
Bare Ground: range 2–5%, mean 3.5%
Parent Material: sedimentary or igneous
Soil Texture: no data

Vegetation Description:
Stands of *Platanus racemosa-Quercus agrifolia* Woodland/Forest form an open to intermittent tree layer (23–48%, mean 37.6%) with hardwoods at 5–15 m tall, a sparse to intermittent shrub layer (0–35%, mean 13.4%) at 0–5 m tall, and a sparse to open herbaceous layer (0–14%, mean 3.6%) at 0–1 m tall. Total vegetation cover is 40–85%, mean cover is 54.4%.

In this association, the tree layer is dominated by *Platanus racemosa* and *Quercus agrifolia*. *Juglans californica* is frequently included in this layer. The shrub layer is sparse to intermittent and often includes *Heteromeles arbutifolia, Malosma laurina,* and *Ceanothus spinosus.* Occasionally, *Toxicodendron diversilobum, Ceanothus megacarpus,* and *Baccharis pilularis* are also included. The herbaceous layer is sparse and includes *Marrubium vulgare, Marah macrocarpus,* and *Stellaria media* in low cover.

Platanus racemosa-Quercus agrifolia/Baccharis salicifolia/Artemisia douglasiana South Coast Woodland/Forest Association

California Sycamore-Coast Live Oak/Mule Fat South Coast Woodland/Forest Association
***Platanus racemosa* Woodland/Forest Alliance**
California Sycamore Woodland/Forest Alliance

Mapping Code: 1458

Local Description

Summary:
This woodland/forest association occurs on often flat to gentle and occasionally somewhat steep slopes at elevations between 0 and 414 m. While slopes are usually flat, the association may be somewhat steep with steepness on southeast or variable exposures. It is codominated by *Platanus racemosa* and *Quercus agrifolia* in the tree layer, *Baccharis salicifolia* in the understory shrub layer, and *Piptatherum miliaceum* is often in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Western Fog Zone, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 0–414 m, mean 184.2 m
Aspect: often flat, occasionally variable or southeast
Slope: range 0–15 degrees, mean 3.2 degrees
Topography (micro; macro): often flat, occasionally concave; bottom to lower slopes
Litter Cover: range 15–75%, mean 55%
Small Rock Cover: range 3–50%, mean 18.7%
Large Rock Cover: range 0–40%, mean 6.3%
Bare Ground: range 5–35%, mean 14.6%
Parent Material: variable but more often depositional
Soil Texture: coarse sand to fine sandy clay

Vegetation Description:
Stands of *Platanus racemosa-Quercus agrifolia/Baccharis salicifolia/Artemisia douglasiana* Woodland/Forest form a sparse to intermittent tree layer (8–40%, mean 20.3%) with hardwoods at 5–20 m tall, a sparse to intermittent shrub layer (1–36%, mean 16.7%) at 0–5 m tall, and a sparse to intermittent herbaceous layer (2–35%, mean 12.2%) at 0–1 m tall. Total vegetation cover is 29–75%, mean cover is 45.3%.

In this association, the tree layer is dominated by *Platanus racemosa* and *Quercus agrifolia*. *Juglans californica* is occasionally included in this layer. The shrub layer is sparse to intermittent and is dominated by *Baccharis salicifolia*. Various other shrubs such as *Toxicodendron diversilobum* and *Sambucus mexicana* are occasionally included in low cover. The herbaceous layer is diverse and often includes *Piptatherum miliaceum, Artemisia douglasiana,* and *Bromus diandrus.* Other herbs include *Hirschfeldia incana, Leymus condensatus,* and *Rubus ursinus*.

Comments:
This is the most widespread of the California sycamore associations in the study area, usually found in seasonal streambeds with high water fluctuation or in wide washes. In this association the sycamore dominates tree canopy with much lower cover of coast live oak. The understory is characterized by the riparian *Baccharis salicifolia* and may also include other riparian or semiriparian shrubs such as *Rosa californica* and *Sambucus mexicana*. The higher proportion of large and small surface rocks suggests a more active flooding regime than other California sycamore associations represented locally.

Platanus racemosa-Quercus agrifolia-Salix lasiolepis Woodland/Forest Association

California Sycamore-Coast Live Oak-Arroyo Willow Woodland/Forest Association
***Platanus racemosa* Woodland/Forest Alliance**
California Sycamore Woodland/Forest Alliance

Mapping Code: 6452

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes with variable aspects at elevations between 35 and 445 m. It is dominated by *Platanus racemosa* and *Quercus agrifolia* in the tree layer, *Salix lasiolepis* in the tree understory, *Toxicodendron diversilobum* and *Salix lasiolepis* in the shrub layer, and a variety of forbs and grasses in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, Dry Inland, Lower Elevation Inland Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 35–445 m, mean 246 m
Aspect: variable but often flat
Slope: range 2–35 degrees, mean 10.4 degrees
Topography (micro; macro): often concave, rarely flat; bottom to upper slopes
Litter Cover: range 15–70%, mean 42.6%
Small Rock Cover: range 2–40%, mean 15.2%
Large Rock Cover: range 1–45%, mean 12%
Bare Ground: range 2–40%, mean 16.1%
Parent Material: variable but more often sedimentary
Soil Texture: silt to moderately fine clay loam

Vegetation Description:
Stands of *Platanus racemosa-Quercus agrifolia-Salix lasiolepis* Woodland/Forest form an open to intermittent tree layer (12–59%, mean 35.9%) with hardwoods at 5–20 m tall, a sparse to intermittent shrub layer (0–45%, mean 13.9%) at 0–10 m tall, and a sparse to intermittent herbaceous layer (0–37%, mean 5.8%) at 0–1 m tall. Total vegetation cover is 30–70%, mean cover is 50.9%.

In this association, the tree layer is dominated by *Platanus racemosa* and *Quercus agrifolia*. *Umbellularia californica, Salix laevigata,* and *Juglans californica* are occasionally included in this layer. *Salix lasiolepis* is dominant in the tree and shrub understory. The shrub layer is also dominated by *Toxicodendron diversilobum*. Occasionally, *Baccharis salicifolia, Ceanothus spinosus,* and *Heteromeles arbutifolia* are also included in the diverse shrub layer. The herbaceous layer is diverse and includes a variety of herbs such as *Piptatherum miliaceum, Artemisia douglasiana, Carduus pycnocephalus, Typha* sp., and *Leymus condensatus*.

Comments:
Of the three of the local associations in the Santa Monica Mountains with a mixture of sycamore and coast live oak, this one seems to be more tied to permanent water. The presence of *Salix lasiolepis* and/or S*. laevigata* and the addition of *Typha* sp. in several of the stands suggest a relatively constant source of water on a gentle slope. However, this association also represents the narrow and steep ravine type of sycamore woodland at least in part of the study area. Some stands may be on steep rocky ravines and follow upslope at a substantial distance from the bases of the mountains. The presence of *Umbellularia californica* in about one-third of the samples along with the constant and frequently codominant *Q. agrifolia* suggests narrow canyon stands. Thus, this appears to be an association with variable ecological setting. It may require further refinement in its definition.

Quercus agrifolia South Coastal Woodland/Forest Association

Coast Live Oak South Coastal Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 6122

Local Description

Summary:
This woodland/forest association occurs on gentle to steep, north-facing slopes at elevations between 0 and 636 m. It is dominated by *Quercus agrifolia* in the tree layer, *Heteromeles arbutifolia* in the understory shrub layer, and variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Simi Hills Inland, Lower Elevation Inland Santa Monica Mountains, Dry Inland, Immediate Coast, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–636 m, mean 325 m
Aspect: variable but often northeast and northwest
Slope: range 2–35 degrees, mean 23.0 degrees
Topography (micro; macro): variable but more often concave; bottom to top slopes
Litter Cover: range 45–95%, mean 72.9%
Small Rock Cover: range 0–30%, mean 6.4%
Large Rock Cover: range 0–15%, mean 3%
Bare Ground: range 0–35%, mean 14.7%
Parent Material: often sedimentary, occasionally depositional or igneous
Soil Texture: medium loam to clay

Vegetation Description:
Stands of *Quercus agrifolia* Woodland/Forest form a sparse to continuous tree layer (9–73%, mean 43%) with hardwoods at 2–20 m tall, a sparse to open shrub layer (0–32%, mean 7.6%) at 0-10 m tall, and a sparse to open herbaceous layer (0–15%, mean 2.1%) at 0–2 m tall. Total vegetation cover is 19–71%, mean cover is 52.7%.

In this association, the tree layer is dominated by *Quercus agrifolia*. *Platanus racemosa, Juglans californica,* and *Umbellularia californica* are occasionally included in this layer. The shrub layer is sparse to open and occasionally includes *Heteromeles arbutifolia, Ceanothus spinosus, Mimulus aurantiacus,* and *Artemisia californica*. The herbaceous layer is diverse and occasionally includes herb such as *Leymus condensatus, Bromus diandrus,* and *Piptatherum miliaceum* in low cover.

Comments:
This is the generic coast live oak woodland of the Santa Monica Mountains within the south coastal region. It has no characteristic understory species in either the shrub or the herb layer. Since more than half of the samples were assessed within the stand and still did not group with other locally defined associations, it is unlikely that this is the result of several of the samples being taken from out of the stand precluding detailed assessment of the understory. In general, the relatively closed canopy, shady understory, and dense litter cover may be the cause of the indistinct understory composition.

PHYSIOGNOMIC SUBGROUP	Natural/Seminatural extremely xeromorphic evergreen woodland
FORMATION	Sclerophyllous extremely xeromorphic evergreen woodland
ALLIANCE	*Quercus agrifolia* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This association is analogous to the *Quercus agrifolia* Association, in which coast live oak is the only principal indicator. This association (or suballiance, as defined by Allen et al. 1991) ranges from central coastal (San Luis Obispo County) to southern California (San Diego County).

Nations:
United States

States or Provinces:
CA

Environmental Description:
This common association occurs on lower slopes and hillsides west of the coastal divide in central and southern California. It occurs largely on west-, east-, and south-facing exposures between 100 and 400 m elevation on moderate to steep slopes. Substrate is largely rocky and/or gravelly loams over sedimentary sandstones and shales.

Vegetation Description:
The canopy is strongly dominated by *Quercus agrifolia* with generally low cover of understory species.

Comments:
This association has relatively high tree cover and low cover of understory species.

Allen et al. 1991, Sawyer and Keeler-Wolf 1995

Quercus agrifolia/Adenostoma fasciculatum Woodland/Forest Association

Coast Live Oak/Chamise Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 6115

Local Description

Summary:
This woodland/forest association occurs on somewhat steep to steep north-facing slopes at low elevations between 0 and 612 m. It is dominated by *Quercus agrifolia* in the tree layer, *Adenostoma fasciculatum* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 0–612 m, mean 353.3 m
Aspect: variable, but often northeast and northwest
Slope: range 15–40 degrees, mean 30.5 degrees
Topography (micro; macro): often flat, occasionally undulating; lower to upper
Litter Cover: no data
Small Rock Cover: range 5–25%, mean 11.7%
Large Rock Cover: range 1–15%, mean 10.3%
Bare Ground: range 10–35%, mean 20%
Parent Material: sedimentary
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Quercus agrifolia/Adenostoma fasciculatum* Woodland/Forest form a sparse to open tree layer (0–15%, mean 8.7%) with hardwoods at 5–15 m tall, an open to intermittent shrub layer (10–58%, mean 36.8%) at 01–5 m tall, and a sparse to intermittent herbaceous layer (0–40%, mean 11.3%) at 0–0.5 m tall. Total vegetation cover is 32–60%, mean cover is 50%.

In this association, the tree layer is dominated by *Quercus agrifolia*. The open to intermittent shrub layer is dominated by *Adenostoma fasciculatum*. Frequently, *Mimulus aurantiacus, Malosma laurina, Ceanothus spinosus, Heteromeles arbutifolia,* and *Rhus ovata* are also included. The herbaceous layer is simple and occasionally includes *Melica imperfecta* and *Leymus condensatus.*

Samples Used in Description: (n = 6)
AA0224cc, rap0155m, rap0406, rap0470m, rap0575, rap1285m

Comments:
This association represents a transitional stage between chaparral dominated by *Adenostoma fasciculatum* and oak woodland dominated by *Quercus agrifolia*, with chamise chaparral in a marginal environmental setting such as on a northerly facing lower slope that is being colonized by oak from an adjacent stand. This type also may be associated with the presence of rocks creating microclimates such as in sandstone areas of Castro Crest or upper Simi Hills. Such situations are apparently uncommon, resulting in only a few stands sampled.

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Similar open woodlands of short *Quercus agrifolia* over *A. fasciculatum* have been seen in other parts of California (e.g., Monterey County, T. Keeler-Wolf personal observation 2004) but have not been sampled. *Q. agrifolia*/Chaparral Association is described from western Riverside County in which the understory contains a mixture of chaparral species including *Adenostoma fasciculatum*. Further, *Q. agrifolia/Adenostoma fasciculatum-Salvia mellifera* Association is described from central California from Monterey south to Ventura County, which is quite similar to this. In this type, *Salvia mellifera* only occurs in 62% of the samples. However, it is insignificant in the Santa Monica Mountains samples. Further descriptive work may show all these types to be equivalent.

Quercus agrifolia/Annual Grass-Herb Woodland/Forest Association

Coast Live Oak/Annual Grass-Herb Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1111

Local Description

Summary:
This woodland/forest association occurs on flat to steep slopes that are often facing northwest at low elevations between 32 and 625 m. It is dominated by *Quercus agrifolia* in the tree layer and *Bromus diandrus* and other herbs in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, Immediate Coast, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 32–625 m, mean 312.2 m
Aspect: variable but often northwest or flat
Slope: range 0–35 degrees, mean 15.9 degrees
Topography (micro; macro): variable but more often undulating or flat; bottom to top slopes
Litter Cover: range 11–88%, mean 64.9%
Small Rock Cover: range 0–25%, mean 5.6%
Large Rock Cover: range 0–85%, mean 4.5%
Bare Ground: range 0–70%, mean 16.1%
Parent Material: depositional or sedimentary, occasionally igneous
Soil Texture: moderately fine sandy clay loam to fine clay

Vegetation Description:
Stands of *Quercus agrifolia*/Annual Grass-Herb Woodland/Forest form a sparse to intermittent tree layer (2–59%, mean 23.1%) with conifers at 0–15 m tall and hardwoods at 2–15 m tall, a sparse to intermittent shrub layer (0–41%, mean 6.8%) at 0–5 m tall, and a sparse to continuous herbaceous layer (4–70%, mean 24.1%) at 0–2 m tall. Total vegetation cover is 11–78%, mean cover is 50.1%.

In this association, the tree layer is dominated by *Quercus agrifolia*. Other trees such as *Eucalyptus* sp*., Quercus lobata,* and *Juglans californica* may infrequently be present at low cover as well. The shrub layer is sparse to intermittent and occasionally includes *Salvia leucophylla, Artemisia californica, Sambucus mexicana,* and *Malosma laurina*. The herbaceous layer is diverse and is dominated by *Bromus diandrus.* Other herbs often include *Brassica nigra, Centaurea melitensis, Marrubium vulgare, Bromus hordeaceus,* and *Avena fatua*.

Other Noteworthy Species:
Brodiaea jolonensis was found in 1 of 41 surveys of this plant community. Regionally, the park considers this species as Locally Rare. CNPS ranks this species as List none, CNPS R-E-D Code is 0-0-0. Global rank is none, and state rank is none. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Calochortus catalinae was found in 1 of 41 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Delphinium parryi was found in 1 of 41 surveys of this plant community, which may be the rare *D. parryi* subsp. *blochmaniae.* Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 3-2-3. Global rank is G4T2, and state rank is S2.2. Federal listing is Species of Concern, and state listing is none (CNPS 2005, SAMO 2004).

Juglans californica was found in 5 of 41 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:

Comments:
This association is the common live oak/grass association in the study area. It has been described elsewhere for California.

Phases:
None

COMMON NAME	Coast Live Oak/Annual Grass-Herb Woodland/Forest Association
SYNONYM	Coast Live Oak/Grass (Allen et al. 1991)
PHYSIOGNOMIC CLASS	Woodland
PHYSIOGNOMIC SUBCLASS	Evergreen woodland
PHYSIOGNOMIC GROUP	Extremely xeromorphic evergreen woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural extremely xeromorphic evergreen woodland
FORMATION	Sclerophyllous extremely xeromorphic evergreen woodland
ALLIANCE	*Quercus agrifolia* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	

Global Description

Distribution:
This association is known from much of central and southern coastal California. This association is known from Solano to San Diego counties.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This association occupies virtually all aspects and slope steepness (0–32 degrees) between 50 and 700 m elevation. Substrate texture is variable, and stands typically occur on sandstones and shales.

Vegetation Description:
The *Quercus agrifolia* overstory is variable in cover from open to continuous cover. The herbaceous layer is usually intermittent to open, especially with forbs (e.g., *Brassica* spp., *Claytonia perfoliata,* and *Lupinus* spp.) and nonnative annual grasses (e.g., *Bromus diandrus, B. hordeaceus,* and *Vulpia* spp.).

Comments:
This association was originally named *Quercus agrifolia*/Grass by Allen et al. (1991) from Solano to Monterey counties, though it has been documented elsewhere in southern California as well as central California. It is called *Quercus agrifolia*/Annual Grass-Herb herein to better describe the annual nature of the understory.

Quercus agrifolia/Ceanothus spinosus Woodland/Forest Association

Coast Live Oak/Greenbark Ceanothus Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1118

Local Description

Summary:
This woodland/forest association occurs on gentle to steep north-facing slopes at low elevations between 136 and 517 m. It is dominated by *Quercus agrifolia* in the tree layer, *Ceanothus spinosus* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 136–517 m, mean 372 m
Aspect: variable but often northwest or northeast
Slope: range 3–43 degrees, mean 24.0 degrees
Topography (micro; macro): variable but more often concave or undulating; bottom to upper slopes
Litter Cover: range 65–85%, mean 76.4%
Small Rock Cover: range 0–15%, mean 5.1%
Large Rock Cover: range 0–5%, mean 1.9%
Bare Ground: range 0–25%, mean 9.4%
Parent Material: more often sedimentary, occasionally igneous or depositional
Soil Texture: coarse loamy sand to moderately fine silty clay loam but more often medium loam

Vegetation Description:
Stands of *Quercus agrifolia/Ceanothus spinosus* Woodland/Forest form an open to continuous tree layer (12–78%, mean 24.7%) with hardwoods at 5–15 m tall, a sparse to intermittent shrub layer (0–55%, mean 34.2%) at 0–10 m tall, and a sparse to intermittent herbaceous layer (0–35%, mean 4.3%) at 0–1 m tall. Total vegetation cover is 41–78%, mean cover is 60.3%.

In this association, the tree layer is dominated by *Quercus agrifolia*. *Juglans californica* is occasionally included in this layer. The shrub layer is sparse to intermittent and is dominated by *Ceanothus spinosus. Heteromeles arbutifolia* and *Mimulus aurantiacus* are often included. The herbaceous layer is diverse and includes *Leymus condensatus, Melica imperfecta, Dryopteris arguta,* and *Marah macrocarpus.*

Quercus agrifolia/Heteromeles arbutifolia Woodland/Forest Association

Coast Live Oak/Toyon Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 6117

Local Description

Summary:
This woodland/forest association occurs on somewhat steep to steep slopes with variable or north-facing aspects at elevations between 87 and 658 m. It is dominated by *Quercus agrifolia* in the tree layer, *Heteromeles arbutifolia* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Simi Hills Inland, Eastern Urban, Dry Inland, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 87–658 m, mean 349.9 m
Aspect: variable but often northeast or northwest
Slope: range 15–40 degrees, mean 30.5 degrees
Topography (micro; macro): variable but often undulating; bottom to top slopes
Litter Cover: range 65–85%, mean 75%
Small Rock Cover: range 0–10%, mean 4.3%
Large Rock Cover: range 0–10%, mean 2.5%
Bare Ground: range 2–20%, mean 7.8%
Parent Material: often sedimentary, occasionally igneous or depositional
Soil Texture: moderately fine sandy clay loam to moderately fine silty clay loam

Vegetation Description:
Stands of *Quercus agrifolia/Heteromeles arbutifolia* Woodland/Forest form a sparse to intermittent tree layer (2–51%, mean 26.3%) with hardwoods at 5–10 m tall, an open to intermittent shrub layer (13–45%, mean 22.3%) at 0–10 m tall, and a sparse herbaceous layer (0–10%, mean 4.1%) at 0–1 m tall. Total vegetation cover is 30–71%, mean cover is 51.9%.

In this association, the tree layer is dominated by *Quercus agrifolia*. The open to intermittent shrub layer is dominated by *Heteromeles arbutifolia*. *Malosma laurina* and *Toxicodendron diversilobum* are often included in low to moderate cover. Occasionally, *Ceanothus spinosus* and *Mimulus aurantiacus* may also be present in low cover. The herbaceous layer is diverse and includes a variety of grasses and forbs with *Leymus condensatus* most frequently occurring. *Bromus* sp.*, Melica imperfecta, Bromus diandrus,* and *Stellaria media* are other herbs present in the stands at low frequency.

Other Noteworthy Species:
Hemizonia minthornii was found in 1 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.2. Federal listing is Species of Concern, and state listing is Rare (CNPS 2005, SAMO 2004).

Juglans californica was found in 4 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Bromus diandrus, Stellaria media, Carduus pycnocephalus, Ageratina adenophora, Avena, Centaurea melitensis, Hirschfeldia incana, Brassica nigra, Bromus hordeaceus, Bromus madritensis, Piptatherum miliaceum, Senecio mikanioides, Avena fatua, Hedera helix, Lolium, Marrubium vulgare, Nicotiana glauca

Samples Used in Description: (n = 18)
AA0219cc, AA0392cc, AA0522, AA0735, AA0783, AA0838, AA0893, AA0919, AA1174, rap0407, rap0714, rap1694, rap1993, rap2280, rap2394, rap2446, rap2636, rap2653

Comments:
Coast live oak and toyon (*Heteromeles arbutifolia*) co-occur commonly throughout coastal, central, and southern California. This association is equivalent to others defined by Allen et al. (1991). Two phases were defined locally: one with relatively high cover of *Heteromeles* in the shrub layer and another with relatively high cover of *Malosma laurina*. Both of these phases overlap sufficiently in environmental and species characteristics to not be distinguished at the association level.

Phases:
Quercus agrifolia/Heteromeles arbutifolia (Coast Live Oak/Toyon) Phase [6117]
Quercus agrifolia/Malosma laurina (Coast Live Oak/Laurel Sumac) Phase [6116]

COMMON NAME	Coast Live Oak/Toyon Woodland/Forest Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Woodland
PHYSIOGNOMIC SUBCLASS	Evergreen woodland
PHYSIOGNOMIC GROUP	Extremely xeromorphic evergreen woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural extremely xeromorphic evergreen woodland
FORMATION	Sclerophyllous extremely xeromorphic evergreen woodland
ALLIANCE	*Quercus agrifolia* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL:	1
ECOLOGICAL REGIONS:	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK:	G5S5

Global Description

Distribution:
Similar associations (e.g., similar *Q. agrifolia/Heteromeles arbutifolia-Toxicodendron diversilobum* Association) are known from much of central and southern coastal California, as far north as Napa County and as far south as Los Angeles County.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This association typically occurs on moderate to steep north- to northeast-facing slopes. The soils are mostly loams over hard sedimentary rocks such as sandstone and shale.

Vegetation Description:
Average cover reported by Allen et al. (1991) for the similar *Q. agrifolia/Heteromeles arbutifolia-Toxicodendron diversilobum* Association is 89% tree cover and about 10% *H. arbutifolia* and *T. diversilobum* cover. A number of woody and herbaceous species occur in < 15% constancy.

Comments:
Allen et al. (1991) have identified two associations of coast live oak with toyon: one with the shrub *Toxicodendron diversilobum* and one with grass species in the understory. It is likely that the currently defined association herein is most similar to the one with *Toxicodendron diversilobum*. Although only 50% of the samples had *T. diversilobum*, the other environmental characteristics suggest a congruence of this and these two types. Since both accounts do not completely detail the herbaceous component of stands, it remains for a more detailed study to reveal whether these two associations can be reduced to synonymy.

Allen et al. 1991, Sawyer and Keeler-Wolf 1995

Quercus agrifolia/Quercus berberidifolia Woodland/Forest Association

Coast Live Oak/Scrub Oak Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 6112

Local Description

Summary:
This woodland/forest association occurs on gentle to somewhat steep slopes with variable aspects at low elevations between 118 and 413 m. It is dominated by *Quercus agrifolia* in the tree layer, *Quercus berberidifolia* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Lower Elevation Inland and Upper Elevation Santa Monica Mountains, Dry Inland, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 118–413 m, mean 248 m
Aspect: variable
Slope: range 4–18 degrees, mean 14.0 degrees
Topography (micro; macro): often undulating, occasionally concave; bottom to lower slopes, sometimes to upper slopes
Litter Cover: range 35–80%, mean 61%
Small Rock Cover: range 1–30%, mean 9%
Large Rock Cover: range 0–10%, mean 2.8%
Bare Ground: range 1–35%, mean 21.7%
Parent Material: sedimentary or depositional
Soil Texture: medium loam to moderately fine sandy clay loam

Vegetation Description:
Stands of *Quercus agrifolia/Quercus berberidifolia* Woodland/Forest form an open to intermittent tree layer (12–38%, mean 23.1%) with hardwoods at 5–15 m tall, a sparse to intermittent shrub layer (9–50%, mean 28.6%) at 0–5 m tall, and a sparse to open herbaceous layer (0–18%, mean 7%) at 0–1m tall. Total vegetation cover is 45–68%, mean cover is 57%.

In this association, the tree layer is dominated by *Quercus agrifolia. Juglans californica* and *Populus fremontii* are occasionally included in this layer. The shrub layer is sparse to intermittent and is dominated by *Quercus berberidifolia*. Occasionally, *Rhamnus ilicifolia, Ceanothus cuneatus, Heteromeles arbutifolia, Sambucus mexicana,* and *Cercocarpus betuloides* are also included. The herbaceous layer is diverse and includes *Bromus* sp., *Centaurea melitensis,* and *Dryopteris arguta*.

Other Noteworthy Species:
Juglans californica was found in 2 of 8 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Polygala cornuta was found in 1 of 8 surveys of this plant community, which could be the rare subspecies *P. C.* var. *fishiae.* Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-1-2. Global rank is G5T4, and state rank is S3.3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Bromus diandrus, Centaurea melitensis, Stellaria media, Galium aparine, Carduus pycnocephalus, Lolium, Marrubium vulgare, Melilotus albus, Piptatherum miliaceum, Vinca major

Samples Used in Description: (n = 8)
AA0470cc, AA0754cc, AA0808, AA1136, rap0459, rap1551m, rap2253, rap2830

Comments:
This association typically occurs in between a lower slope or bottom slope position while *Quercus agrifolia* Woodland, *Q. agrifolia/Heteromeles arbutifolia*, or other *Q. agrifolia* associations occur and a middle or lower slope position with *Quercus berberidifolia A*lliance stands. These oaks

stands are not usually adjacent or transitional throughout the Santa Monica Mountains, and they occur in large enough stands so as not to be considered strictly ecotonal.

Phases:
None

COMMON NAME	Coast Live Oak/Scrub Oak Woodland/Forest Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Woodland
PHYSIOGNOMIC SUBCLASS	Evergreen woodland
PHYSIOGNOMIC GROUP	Extremely xeromorphic evergreen woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural extremely xeromorphic evergreen woodland
FORMATION	Sclerophyllous extremely xeromorphic evergreen woodland
ALLIANCE	*Quercus agrifolia* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL:	1
ECOLOGICAL REGIONS:	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK:	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
A somewhat similar association, the *Quercus agrifolia-Umbellularia californica/Heteromeles arbutifolia-Quercus berberidifolia* Association, has been defined. It differs from this association by having *Umbellularia* in > 75% of the samples, and *Arbutus menziesii* in about half of the samples. It is perhaps a northern California analog to this association.

Allen et al. 1991

Quercus agrifolia/Salvia leucophylla-Artemisia californica Woodland/Forest Association

Coast Live Oak/Purple Sage-California Sagebrush Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1116

Local Description

Summary:
This woodland/forest association occurs on somewhat steep to steep slopes that are often north facing at elevations between 53 and 420 m. It is dominated by *Quercus agrifolia* in the tree layer, *Salvia leucophylla* and *Artemisia californica* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Lower Elevation Inland Santa Monica Mountains, Immediate Coast, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 53–420 m, mean 301.1 m
Aspect: variable but often northwest or northeast
Slope: range 15–35 degrees, mean 26.0 degrees
Topography (micro; macro): often convex or undulating, occasionally flat; bottom to top slopes
Litter Cover: range 20–75%, mean 49.4%
Small Rock Cover: range 2–20%, mean 10.3%
Large Rock Cover: range 0–2%, mean 1.1%
Bare Ground: range 15–50%, mean 28.8%
Parent Material: often sedimentary, occasionally depositional or igneous
Soil Texture: moderately fine clay loam to fine sandy clay

Vegetation Description:
Stands of *Quercus agrifolia/Salvia leucophylla-Artemisia californica* Woodland/Forest form a sparse to intermittent tree layer (8–35%, mean 19.3%) with hardwoods at 2–15 m tall, an open to intermittent shrub layer (10–50%, mean 27.5%) at 0–5 m tall, and a sparse to open herbaceous layer (0–22%, mean 5.6%) at 0–1 m tall. Total vegetation cover is 32–64%, mean cover is 49.9%.

In this association, the tree layer is dominated by *Quercus agrifolia*. *Juglans californica* is occasionally included in this layer. The open to intermittent shrub layer is dominated by *Salvia leucophylla* and *Artemisia californica.* Occasionally, *Malosma laurina* and *Malacothamnus fasciculatus* are also included. The herbaceous layer is diverse and includes *Leymus condensatus, Brassica nigra, Bromus diandrus,* and *Centaurea melitensis.*

Comments:
This is a locally common association that is largely endemic to the Santa Monica Mountains and Ventura region of the southern California coast. It represents the most common expression of coast live oak and coastal sage scrub species. These stands appear to be mature stands with lengthening intervals between fires, which have allowed for oaks and coastal scrub to recolonize areas and develop into mature trees and shrubs that may have been dominated more by grasses under a regime of higher frequency fire. Alternatively, this type may be a type recovering from grazing pressure more than a release from fires (J. Christian, personal observation).

Comments:
A similar association has been reported by Allen et al. (1991). It is the *Quercus agrifolia/ Artemisia californica/*Grass Association. It is likely to be the "parent" suballiance to this association. It is identified from Santa Clara to San Diego counties with *Artemisia californica* as the overall constant shrub at 88% and *Salvia leucophylla* at 13% constancy. However, since *A. californica* has a much wider geographic range than S*. leucophylla*, it is likely that if the southern California samples were analyzed separately, they would also have shown a higher constancy of S*. leucophylla*, thus mirroring the Santa Monica Mountains situation.

Quercus agrifolia/Toxicodendron diversilobum Woodland/Forest Association

Coast Live Oak/Poison Oak Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1117

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes with variable aspects at low elevations between 40 and 577 m. It is dominated by *Quercus agrifolia* in the tree layer. *Toxicodendron diversilobum* is characteristic in the understory shrub layer, and a variety of grasses and forbs is in the herbaceous layer.

Distribution:
This association is sampled in the Western Fog Zone, Upper Elevation Santa Monica Mountains, Immediate Coast, Eastern Urban, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Dry Inland of the study area.

Environmental Description:
Elevation: range 40–577 m, mean 286.4 m
Aspect: variable, often northwest or northeast
Slope: range 1–40 degrees, mean 20.7 degrees
Topography (micro; macro): variable; bottom to top slopes
Litter Cover: range 45–85%, mean 72.2%
Small Rock Cover: range 0–15%, mean 4.2%
Large Rock Cover: range 0–20%, mean 3%
Bare Ground: range 2–25%, mean 12%
Parent Material: often sedimentary, occasionally depositional or igneous
Soil Texture: medium to very fine loamy sand to moderately fine sandy clay loam but often medium loam

Vegetation Description:
Stands of *Quercus agrifolia/Toxicodendron diversilobum* Woodland/Forest form a sparse to continuous tree layer (5–74%, mean 31.8%) with conifers at 0–20 m tall and hardwoods at 2–35 m tall, a sparse to intermittent shrub layer (6–56%, mean 24.8%) at 0–10 m tall, and a sparse to open herbaceous layer (0–15%, mean 5.3%) at 0–2 m tall. Total vegetation cover is 38–90%, mean cover is 58.6%.

In this association, the tree layer is dominated by *Quercus agrifolia*. The shrub layer is sparse to intermittent and is characterized by *Toxicodendron diversilobum*. Frequently, *Mimulus aurantiacus* and *Heteromeles arbutifolia* are also included. *Malosma laurina, Artemisia californica, Salvia leucophylla, Sambucus mexicana,* and *Rhamnus ilicifolia* are occasionally included in the shrub layer. The herbaceous layer is diverse and includes *Leymus condensatus, Marah macrocarpus, Bromus diandrus, Piptatherum miliaceum,* and *Melica imperfecta.*

Comments:
This is a common association in the Santa Monica Mountains. It can be distinguished from others of this alliance by the relatively high cover of understory shrubs (about 25%) most of which are *Toxicodendron diversilobum* and *Mimulus aurantiacus.* Two phases have been distinguished: one with high cover of *T. diversilobum* and the other with high cover of *M. aurantiacus.* Both have sufficient overlap in species and environmental characteristics to be combined.

Phases:
Quercus agrifolia/Toxicodendron diversilobum (Coast Live Oak/Poison Oak) Phase [1117]
Quercus agrifolia/Mimulus aurantiacus (Coast Live Oak/Bush Monkey Flower) Phase [6113]

COMMON NAME	Coast Live Oak/Poison Oak Woodland/Forest Association

ALLIANCE	*Quercus agrifolia* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL:	1
ECOLOGICAL REGIONS:	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK:	

Global Description

Distribution:
This association is known from other parts of central and south coastal California (Allen et al. 1991).

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Several other *Quercus agrifolia* associations are characterized by the presence of *T. diversilobum*. These include *Q. agrifolia/T. diversilobum*/Grass (Allen et al. 1991), *Q. agrifolia/T. diversilobum-Riparian,* and *Q. agrifolia/T. diversilobum*/Grass (Evens and San 2005), and *Q. agrifolia/T. diversilobum-(Corylus cornuta)* (NatureServe et al. 2003a). All these have distinguishing biogeographic and environmental features that justify keeping these as separate associations.

Quercus agrifolia-Juglans californica Woodland/Forest Association

Coast Live Oak-California Walnut Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1115

Local Description

Summary:
This woodland/forest association occurs on moderately steep to very steep slopes with variable aspects at low to mid elevations between 58 and 869 m. It is dominated by *Quercus agrifolia* and *Juglans californica* in the tree layer. *Toxicodendron diversilobum* is characteristic in the understory shrub layer. A variety of grasses and forbs occurs in the herbaceous layer with *Leymus condensatus* most frequently occurring.

Distribution:
This association is sampled in the Eastern Urban, Upper Elevation Santa Monica Mountains, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Dry Inland, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 58–869 m, mean 275 m
Aspect: often northeast or northwest, sometimes southwest or variable
Slope: range 7–46 degrees, mean 25.4 degrees
Topography (micro; macro): variable but more often undulating or concave; bottom to upper slopes
Litter Cover: range 35–90%, mean 67%
Small Rock Cover: range 0–50%, mean 8.4%
Large Rock Cover: range 0–3%, mean 0.8%
Bare Ground: range 2–35%, mean 11%
Parent Material: variable but more often sedimentary, occasionally igneous or depositional
Soil Texture: medium loam to moderately fine sandy clay loam but more often moderately fine clay loam

Vegetation Description:
Stands of *Quercus agrifolia-Juglans californica* Woodland/Forest form an open to continuous tree layer (0–72%, mean 36.5%) with hardwoods at 5–15 m tall, a sparse to intermittent shrub layer (2–63%, mean 16.6%) at 0–10 m tall, and a sparse to intermittent herbaceous layer (0–46%, mean 7.3%) at 0–1 m tall. Total vegetation cover is 44–85%, mean cover is 58.3%.

In this association, the tree layer is dominated by *Quercus agrifolia* and *Juglans californica*. *Umbellularia californica* is infrequently included in this layer at low cover. The shrub layer is sparse to intermittent and is characterized by *Toxicodendron diversilobum*, usually with highest cover. *Heteromeles arbutifolia* and other shrubs, such as *Sambucus mexicana, Artemisia californica,* and *Mimulus aurantiacus,* are often found in lower cover. The herbaceous layer is diverse with *Leymus condensatus* often present and various herbs occasionally present such as *Marrubium vulgare, Bromus* sp., *Piptatherum miliaceum,* and *Brassica nigra*.

Comments:
This association is largely endemic to the Santa Monica Mountains and immediate surroundings. It is differentiated from others of this alliance by the constant presence of *Juglans californica* as a sub- or occasionally codominant. Also as a general note, cover values of *Juglans* are likely to

average higher than recorded because some sampling was done during periods when the leaves of this deciduous species were largely absent.

Two phases have been identified: one with little understory shrubs or herbs and another with high cover of *Toxicodendron diversilobum*.

Phases:
Quercus agrifolia-Juglans californica (Coast Live Oak-California Walnut) Phase [1115]
Juglans californica-Quercus agrifolia/Toxicodendron diversilobum (California Walnut-Coast Live Oak/Poison Oak) Phase [6311]

Quercus agrifolia-Salix lasiolepis Woodland/Forest Association

Coast Live Oak-Arroyo Willow Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 6114

Local Description

Summary:
This woodland/forest association occurs on gentle to somewhat steep slopes with variable aspects at low elevations between 119 and 527 m. It is dominated by *Quercus agrifolia* in the tree layer and *Salix lasiolepis* in the understory tree layer. A variety of grasses and forbs is often abundant in the herbaceous layer.

Distribution:
This association is sampled in the Western Fog Zone, Dry Inland, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 119–527 m, mean 345 m
Aspect: variable
Slope: range 2–15 degrees, mean 10.7 degrees
Topography (micro; macro): variable but more often concave; bottom to mid slopes
Litter Cover: range 0–80%, mean 40%
Small Rock Cover: range 0–8%, mean 4.3%
Large Rock Cover: range 0–2%, mean 0.7%
Bare Ground: range 15–70%, mean 33.3%
Parent Material: often sedimentary, occasionally igneous
Soil Texture: coarse loamy sand

Vegetation Description:
Stands of *Quercus agrifolia-Salix lasiolepis* Woodland/Forest form an open to intermittent tree layer (27–63%, mean 46.8%) with conifers at 0–15 m tall and hardwoods at 5–15 m tall, a sparse to open shrub layer (1–16%, mean 6.7%) at 0–5 m tall, and a sparse herbaceous layer (0–7%, mean 3.3%) at 0–1 m tall. Total vegetation cover is 43–65%, mean cover is 56.2%.

In this association, the tree layer is dominated by *Quercus agrifolia*. *Salix lasiolepis* is frequently in the understory or overstory tree layer, while *Salix laevigata* may also occur in the overstory tree layer. The shrub layer is sparse to open and frequently includes *Heteromeles arbutifolia* and *Toxicodendron diversilobum*. The herbaceous layer is diverse and includes *Piptatherum miliaceum, Artemisia douglasiana,* and *Rorippa nasturtium-aquaticum*.

Quercus agrifolia-Umbellularia californica Woodland/Forest Association

Coast Live Oak-California Bay Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1114

Local Description

Summary:
This woodland/forest association occurs on gentle to steep, often north-facing slopes at low to mid elevations between 0 and 851 m. It is dominated by *Quercus agrifolia* and *Umbellularia californica* in the tree layer, *Heteromeles arbutifolia* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 0–851 m, mean 399 m
Aspect: variable but often northeast or northwest
Slope: range 2–36 degrees, mean 24.8 degrees
Topography (micro; macro): variable but more often concave or undulating; bottom to top slopes
Litter Cover: range 80–80%, mean 80%
Small Rock Cover: range 1–9%, mean 4.4%
Large Rock Cover: range 0–25%, mean 7.2%
Bare Ground: range 1–15%, mean 6.8%
Parent Material: often sedimentary, occasionally igneous, metamorphic, or depositional
Soil Texture: more often medium loam, less often moderately fine silty clay loam

Vegetation Description:
Stands of *Quercus agrifolia-Umbellularia californica* Woodland/Forest form an open to continuous tree layer (7–70%, mean 40.3%) with hardwoods at 2–20 m tall, a sparse to intermittent shrub layer (0–50%, mean 15.7%) at 0–5 m tall, and a sparse to open herbaceous layer (0–15%, mean 1.7%) at 0–2 m tall. Total vegetation cover is 40–78%, mean cover is 57%.

In this association, the tree layer is dominated by *Quercus agrifolia* and *Umbellularia californica*. *Platanus racemosa* and *Juglans californica* are occasionally included in this layer. The shrub layer is sparse to intermittent and is characterized by *Heteromeles arbutifolia* at low cover. Frequently, *Toxicodendron diversilobum* and *Mimulus aurantiacus* are also included. The herbaceous layer is diverse and occasionally includes *Leymus condensatus, Rubus ursinus, Marah macrocarpus,* and *Dryopteris arguta.*

Comments:
This is the common oak and bay forest of the Santa Monica Mountains. It is widespread on mesic slopes and in canyons at lower to mid elevations. Coast live oak is usually clearly dominant, but California bay accounts for approximately half the total tree cover. Two phases have been identified, one with significantly higher *Toxicodendron* cover than the other.

Phases:
Quercus agrifolia-Umbellularia californica (Coast Live Oak-California Bay) Phase [1114]
Quercus agrifolia-Umbellularia californica/Toxicodendron diversilobum (Coast Live Oak-California Bay/Poison Oak) Phase [6119]

Quercus agrifolia-Umbellularia californica/Ceanothus oliganthus Woodland/Forest Association

Coast Live Oak-California Bay/Hairy Leaf Ceanothus Woodland/Forest Association
***Quercus agrifolia* Woodland/Forest Alliance**
Coast Live Oak Woodland/Forest Alliance

Mapping Code: 1119

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes, often with north-facing aspects at low to mid elevations between 298 and 801 m. *Quercus agrifolia* and *Umbellularia californica* are dominant in the tree layer, *Ceanothus oliganthus* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 298–801 m, mean 588.3 m
Aspect: variable but often northeast
Slope: range 4–35 degrees, mean 23.2 degrees
Topography (micro; macro): variable; bottom to top slopes
Litter Cover: range 15–80%, mean 47.5%
Small Rock Cover: range 3–25%, mean 10.6%
Large Rock Cover: range 0–25%, mean 8.4%
Bare Ground: range 5–15%, mean 10.8%
Parent Material: igneous, depositional, or sedimentary
Soil Texture: medium loam to moderately fine sandy clay loam

Vegetation Description:
Stands of *Quercus agrifolia-Umbellularia californica/Ceanothus oliganthus* Woodland/Forest form an open to intermittent tree layer (18–38%, mean 32.4%) with hardwoods at 5–10 m tall, a sparse to intermittent shrub layer (6–45%, mean 26.1%) at 0–10 m tall, and a sparse to open herbaceous layer (0–25%, mean 2.9%) at 0–1 m tall. Total vegetation cover is 40–90%, mean cover is 59.6%.

In this association, the tree layer is dominated by *Quercus agrifolia* and *Umbellularia californica*. *Juglans californica* is occasionally included in this layer. The shrub layer is sparse to intermittent and is dominated by *Ceanothus oliganthus. Heteromeles arbutifolia* is often included. *Quercus berberidifolia, Mimulus aurantiacus, Adenostoma sparsifolium,* and *Ribes malvaceum* are occasionally present in low cover. The herbaceous layer is simple and occasionally includes *Dryopteris arguta, Piptatherum miliaceum, Leymus condensatus, Melica imperfecta,* and *Silene gallica* in low cover.

AA0473cc, AA1226, rap0282m, rap0284, rap0696m, rap0777m, rap0784, rap2425, rap2836

Comments:
This association is characteristic of the more inland or upper elevation mixed oak and bay woodlands of the project area. In general, *Ceanothus oliganthus* does not occur much below 615 m in the main portion of the Santa Monica Mountains, thus the combination of these species is often found on shaded upper slopes and in upper canyons. In the less coastal Simi Hills, this association may occur at lower elevations.

Quercus lobata/Annual Grass-Herb Woodland/Forest Association

Valley Oak/Annual Grass-Herb Woodland/Forest Association
***Quercus lobata* Woodland/Forest Alliance**
Valley Oak Woodland/Forest Alliance

Mapping Code: 1321

Local Description

Summary:
This woodland/forest association occurs on flat to steep slopes with variable aspect at low elevations between 230 and 418 m. It is dominated by *Quercus lobata* in the tree layer, and various herbs and grasses, such as *Brassica nigra*, *Bromus diandrus,* and *Lactuca serriola,* in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 230–418 m, mean 297 m
Aspect: variable
Slope: range 0–35 degrees, mean 12.8 degrees
Topography (micro; macro): variable but more often concave; bottom to top slopes
Litter Cover: range 25–85%, mean 55.8%
Small Rock Cover: range 0–25%, mean 7.8%
Large Rock Cover: range 0–5%, mean 1.1%
Bare Ground: range 0–63%, mean 21.1%
Parent Material: often depositional, occasionally sedimentary or igneous
Soil Texture: medium loam to fine clay

Vegetation Description:
Stands of *Quercus lobata*/Annual Grass-Herb Woodland/Forest form a sparse to intermittent tree layer (4–41%, mean 15.8%) with hardwoods at 2–15 m tall, a sparse shrub layer (0–5%, mean 1%) at 0–5 m tall, and an open to intermittent herbaceous layer (16–53%, mean 28.3%) at 0–2 m tall. Total vegetation cover is 20–60%, mean cover is 42.3%.

In this association, the tree layer is dominated by *Quercus lobata*. *Quercus agrifolia* is occasionally included in this layer. The shrub layer is sparse and infrequently includes species such as *Baccharis salicifolia* and *Salvia leucophylla*. The herbaceous layer is dominated by nonnative species, characteristically including *Brassica nigra* and *Bromus diandrus.* Other herbs often include *Lactuca serriola*, *Bromus* sp., *Erodium* sp., and other grasses and forbs.

Other Noteworthy Species:
Dudleya cymosa was found in 1 of 12 surveys of this plant community, which could be one of the rare subspecies such as *D. C.* subsp. *ovatifolia, D. C.* subsp. *marcescens,* or *D. C.* subsp. *agourensis.* Regionally, the park considers these three species as Rare. CNPS ranks them as List 1B, and CNPS R-E-D Code is 3-2-3. Global rank is G5T2 or G5T1, and state rank is S2.2 or S1.2. Federal listing is Threatened, and state listing is none or Rare (CNPS 2005, SAMO 2004).

Juglans californica was found in 3 of 12 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Brassica nigra, Bromus diandrus, Lactuca serriola, Avena fatua, Malva parviflora, Centaurea melitensis, Bromus hordeaceus, Hirschfeldia incana, Melilotus indicus, Avena, Erodium moschatum, Erodium cicutarium, Piptatherum miliaceum, Centaurea solstitialis, Medicago polymorpha, Erodium, Bromus madritensis, Arundo donax, Carduus pycnocephalus, Conyza canadensis, Foeniculum vulgare, Lolium, Nicotiana glauca, Rumex crispus

Samples Used in Description: (n = 12)
AA0355, AA0541, AA0685, AA1133, rap1240, rap1496, rap1497, rap1498, rap2245, rap2314, rap2379, rap2631

Comments:
Two associations of this alliance occur in the study area. Both represent the southernmost representation of this alliance. Interestingly, both associations also are represented throughout much of the full range of this alliance, occurring far north into northern California. The association name has been modified somewhat from Allen et al. (1991), where it was called *Q. lobata*/Grass. The renaming here suggests that it also includes annual forbs as well as grasses.

Phases:
None

COMMON NAME	Valley Oak/Annual Grass-Herb Woodland/Forest Association
SYNONYM	Valley Oak/Grass (Allen et al. 1991)

ALLIANCE	*Quercus lobata* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from northern, central, and southern coastal California from Mendocino to Los Angeles counties inland to Contra Costa, Santa Clara, San Benito, and Kern counties.

Nations:
United States

States or Provinces:
CA

Environmental Description:
The association occurs on mostly loamy soils of granitic or sedimentary parent material. It occurs on all aspects with slope usually < 35% with elevation below 1,710 m.

Vegetation Description:
Valley oak is the dominant tree in the overstory in open to moderately open woodlands. Shrub species are rarely present, and grasses are in high abundance.

Comments:
See local description.

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes with variable aspects at low elevations between 236 and 465 m. It is dominated by *Quercus agrifolia* and *Quercus lobata* in the tree layer and *Brassica nigra* in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Lower Elevation Inland Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 236–465 m, mean 337 m
Aspect: variable
Slope: range 2–35 degrees, mean 17.7 degrees
Topography (micro; macro): variable but more often concave; bottom to top slopes
Litter Cover: range 20–85%, mean 58.6%
Small Rock Cover: range 1–30%, mean 7.2%
Large Rock Cover: range 0–8%, mean 1.5%
Bare Ground: range 2–50%, mean 17.8%
Parent Material: often sedimentary, occasionally depositional
Soil Texture: moderately fine clay loam to fine clay

Vegetation Description:
Stands of *Quercus lobata-Quercus agrifolia*/Annual Grass-Herb Woodland/Forest form a sparse to continuous tree layer (0–67%, mean 22.7%) with hardwoods at 5–15 m tall, a sparse to intermittent shrub layer (0–47%, mean 6.7%) at 0–5 m tall, and a sparse to intermittent herbaceous layer (1–60%, mean 26.3%) at 0–1 m tall. Total vegetation cover is 27–70%, mean cover is 51.5%.

In this association, the tree layer is codominated by *Quercus agrifolia* and *Quercus lobata. Juglans californica* is occasionally included in this layer. The shrub layer is sparse to intermittent and occasionally includes *Salvia leucophylla, Artemisia californica, Sambucus mexicana,* and *Hazardia squarrosa*. The herbaceous layer is diverse and often includes *Brassica nigra* and *Bromus diandrus.* Other herbs occasionally include *Hirschfeldia incana, Centaurea melitensis, Lactuca serriola, Eriogonum elongatum, Bromus hordeaceus, Lessingia filaginifolia, Leymus condensatus,* and *Marrubium vulgare.*

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Juglans californica was found in 7 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Brassica nigra, Bromus diandrus, Hirschfeldia incana, Centaurea melitensis, Lactuca serriola, Bromus hordeaceus, Marrubium vulgare, Medicago polymorpha, Avena fatua, Carduus pycnocephalus, Cirsium vulgare, Avena, Melilotus indicus, Erodium cicutarium, Centaurea solstitialis, Lolium, Malva parviflora, Bromus madritensis, Salsola tragus, Galium aparine, Nicotiana glauca, Silybum marianum, Verbascum blattaria

Comments:
This association is characterized by codominance of valley and coast live oak with a largely nonnative annual grass and herb understory. Two associations of this alliance occur in the study

area. Both represent the southernmost representation of this alliance. Interestingly, both associations also are represented throughout much of the full range of this alliance, occurring far north into northern California. The association name has been modified somewhat from Allen et al. (1991), where it was called *Quercus lobata-Q. agrifolia*/Grass. The renaming here suggests that it also includes annual forbs as well as grasses.

Phases:
None

COMMON NAME	Valley Oak-Coast Live Oak/Annual Grass Herb Woodland/Forest Association
PHYSIOGNOMIC CLASS	Woodland
PHYSIOGNOMIC SUBCLASS	Deciduous woodland
PHYSIOGNOMIC GROUP	Cold-deciduous woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural cold-deciduous woodland
FORMATION	Cold-deciduous woodland
ALLIANCE	*Quercus lobata* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from central California to southern California ranging from Santa Clara County to Los Angeles County and inland to Kern, Merced, San Benito, and Santa Clara counties.

Nations:
United States

States or Provinces:
CA

Environmental Description:
The association usually occurs on deep clay soils at elevations ranging from near sea level to more than 1,000 m (in the Tehachapi Mountains and northern coast range).

Vegetation Description:
These are moderately open woodlands to very open woodlands (10–50% tree cover), with a shared dominance of *Q. lobata* and *Q. agrifolia* along with a largely herbaceous understory of grasses and herbs.

Comments:
It remains to be seen if the presence of certain southern California shrubs, such as *Salvia leucophylla,* in about one-third of the samples is sufficient to differentiate the local stands from other similar stands in northern and central California.

Quercus lobata-Salix lasiolepis Woodland/Forest Association

Valley Oak-Arroyo Willow (provisional) Woodland/Forest Association
***Quercus lobata* Woodland/Forest Alliance**
Valley Oak Woodland/Forest Alliance

Mapping Code: 1324

Local Description

Summary:
This woodland/forest association occurs on gentle to moderate slopes with variable aspect at low elevations between 230 and 318 m. It is dominated by *Quercus lobata* in the overstory tree layer. *Salix lasiolepis* is present in either the tree or shrub layer, and *Quercus agrifolia* is often present in the understory tree layer. *Baccharis salicifolia* is abundant in the understory shrub layer, and a variety of grasses and forbs is found in the herbaceous layer. This is considered a provisional association because only three samples of this type have been collected.

Distribution:
This association is sampled in the Dry Inland and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 230–318 m, mean 239 m
Aspect: variable or flat/none
Slope: range 2–15 degrees, mean 6.3 degrees
Topography (micro; macro): concave; bottom to lower slopes
Litter Cover: range 35–65%, mean 55%
Small Rock Cover: range 5–8%, mean 7%
Large Rock Cover: range 2–2%, mean 2%
Bare Ground: range 10–35%, mean 20%
Parent Material: depositional or sedimentary
Soil Texture: medium loam

Vegetation Description:
Stands of *Quercus lobata-Salix lasiolepis* Woodland/Forest form an open to intermittent tree layer (25–60%, mean 42.3%) with hardwoods at 5–15 m tall, a sparse to open shrub layer (2–11%, mean 7.7%) at 0–2 m tall, and a sparse to open herbaceous layer (2–25%, mean 12%) at 0–1 m tall. Total vegetation cover is 60–65%, mean cover is 62%.

In this association, the tree layer is dominated by *Quercus lobata*. *Salix lasiolepis* is found in the tree or shrub layer with moderate to abundant cover. *Quercus agrifolia* is found in low cover in the understory tree layer, and *Salix laevigata* is occasionally included in the tree layer. The shrub layer is sparse to open and often includes *Baccharis salicifolia* and *Baccharis pilularis.* The herbaceous layer is simple and occasionally includes *Bromus diandrus* and *Rubus ursinus.*

PHYSIOGNOMIC SUBGROUP	Natural/Seminatural cold-deciduous woodland
FORMATION	Cold-deciduous woodland
ALLIANCE	*Quercus lobata* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G2S2?

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This provisional association is likely to occur elsewhere within the range of the *Quercus lobata* Alliance. Many stands of *Q. lobata* in the Sacramento Valley are true riparian stands. Although no associations have been defined with *Q. lobata* and S*. lasiolepis*, it is likely that this association

occurs elsewhere in the south and central coast ranges of California and possibly in the Sacramento and San Joaquin valleys as well.

Salix laevigata-Salix lasiolepis Woodland/Forest Suballiance

Red Willow-Arroyo Willow Woodland/Forest Suballiance
***Salix laevigata* Woodland/Forest Alliance**
Red Willow Woodland/Forest Alliance

Mapping Code: 1410

Local Description

Summary:
This woodland/forest association occurs on flat to somewhat steep slopes with variable aspects at elevations between 69 and 334 m. It is dominated by *Salix laevigata* and *S. lasiolepis* in both the tree and shrub layers. A variety of grasses and forbs occurs in the herbaceous layer at low cover.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains, Dry Inland, Upper Elevation Santa Monica Mountains, Western Fog Zone, and Immediate Coast of the study area.

Environmental Description:
Elevation: range 69–334 m, mean 224 m
Aspect: variable but more often flat
Slope: range 0–15 degrees, mean 5.5 degrees
Topography (micro; macro): concave or flat; bottom to lower slopes
Litter Cover: range 40–90%, mean 68.3%
Small Rock Cover: range 0–25%, mean 9.3%
Large Rock Cover: range 0–15%, mean 4.3%
Bare Ground: range 0–20%, mean 12.5%
Parent Material: often depositional, occasionally sedimentary or igneous
Soil Texture: coarse loamy sand to moderately fine silty clay loam

Vegetation Description:
Stands of *Salix laevigata-Salix lasiolepis* Woodland/Forest form a sparse to intermittent tree layer (0–66%, mean 37.9%) with conifers at 0–10 m tall and hardwoods at 0–10 m tall, a sparse to intermittent shrub layer (0–60%, mean 11.9%) at 0–10 m tall, and a sparse to open herbaceous layer (0–25%, mean 4.7%) at 0–5 m tall. Total vegetation cover is 30–65%, mean cover is 54.4%.

In this association, the tree layer is dominated by *Salix laevigata* and *S. lasiolepis. Quercus agrifolia* occasionally is included in this layer. The shrub layer is sparse to intermittent and occasionally includes *Baccharis pilularis, Eriogonum fasciculatum,* and *Baccharis salicifolia*. The herbaceous layer includes a variety of grasses and forbs at low cover and frequency including *Piptatherum miliaceum, Arundo donax, Typha* sp.*, Bromus* sp.*, Equisetum* sp., and *Leymus condensatus*.

Other Noteworthy Species:
Juglans californica was found in 3 of 14 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Schinus molle, Piptatherum miliaceum, Arundo donax, Hirschfeldia incana, Robinia, Ricinus communis, Cortaderia, Tamarix, Bromus diandrus, Foeniculum vulgare, Myoporum laetum, Phoenix canariensis, Rorippa nasturtium-aquaticum, Ulmus parvifolia

Samples Used in Description: (n = 14)
AA0144cc, AA0354, AA0422, AA0501, AA0507, AA0571, rap1744, rap2151, rap2152, rap2231m, rap2347, rap2577, rap2719, rap2720

Comments:
Salix laevigata and *S. lasiolepis* were sometimes difficult to identify in the field, so their cover estimates were combined into one value in the species list. This is considered a suballiance in which further variation must be defined via complete species inventory. Urban runoff may contribute to the existence of this type.

Phases:
None

COMMON NAME	Red Willow-Arroyo Willow Woodland/Forest Suballiance
PHYSIOGNOMIC CLASS	Woodland
PHYSIOGNOMIC SUBCLASS	Deciduous woodland
PHYSIOGNOMIC GROUP	Cold-deciduous woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural cold-deciduous woodland
FORMATION	Cold-deciduous woodland
ALLIANCE	*Salix laevigata* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S3?

Global Description

Distribution:
This vegetation type has also been described in northern California from the Suisun Marsh, and an association of these two willow species with an understory species associate is described in southern California. It likely occurs in many areas of California and potentially adjacent states.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This vegetation type occurs in permanently to intermittently flooded channels, stream banks, and sloughs.

Vegetation Description:
In Suisun Marsh and southern California, an association is defined by a codominance of S*. laevigata* and *S. lasiolepis*.

Comments:
This mixed red and arroyo willow type as defined in the Santa Monica Mountains clearly needs further definition based on species composition.

Salix laevigata-Salix lasiolepis/Artemisia douglasiana-Rubus ursinus/Annual Grass-Herb Woodland/Forest Association

Red Willow-Arroyo Willow/Douglas Mugwort-California Blackberry/Annual Grass-Herb (Provisional) Woodland/Forest Association
***Salix laevigata* Woodland/Forest Alliance**
Red Willow Woodland/Forest Alliance

Mapping Code: 1413

Local Description

Summary:
This woodland/forest association occurs on flat to gentle slopes with no or variable aspect at low elevations between 237 and 325 m. *Salix laevigata* and *S. lasiolepis* dominate in the tree, understory tree, and shrub layers. *Bromus diandrus, Rubus ursinus, Artemisia douglasiana,* and *Marrubium vulgare* are constants in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 237–325 m, mean 293 m
Aspect: variable but more often flat
Slope: range 0–3 degrees, mean 1.7 degrees
Topography (micro; macro): flat or concave; bottom slopes
Litter Cover: range 60–85%, mean 73.3%
Small Rock Cover: range 0–10%, mean 4%
Large Rock Cover: range 0–3%, mean 1%
Bare Ground: range 5–30%, mean 15%
Parent Material: depositional or sedimentary
Soil Texture: moderately fine silty clay loam

Vegetation Description:
Stands of *Salix laevigata-Salix lasiolepis/Artemisia douglasiana-Rubus ursinus*/Annual Grass-Herb Woodland/Forest form an intermittent tree layer (33–40%, mean 35.3%) with hardwoods at 5–15 m tall, a sparse to open shrub layer (0–15%, mean 5%) at 0.5–5 m tall, and a sparse to open herbaceous layer (5–15%, mean 11%) at 0–1 m tall. Total vegetation cover is 43–51%, mean cover is 47.3%.

In this association, the tree layer is dominated by *Salix,* most likely both *Salix laevigata* and *S. lasiolepis. Quercus lobata* is occasionally included in this layer and the understory at low cover, and *Quercus agrifolia* is often in the understory at low cover. The sparse to open shrub layer is dominated by *Salix* sp., and *Baccharis salicifolia* and *Salvia spathacea* are often present. The herbaceous layer is diverse and includes a variety of grasses and forbs, in which *Bromus diandrus, Rubus ursinus, Artemisia douglasiana,* and *Marrubium vulgare* characteristically occur.

Other Noteworthy Species:
None

Nonnative Species:
Bromus diandrus, Marrubium vulgare, Piptatherum miliaceum, Brassica nigra, Cirsium vulgare, Galium aparine, Melilotus indicus, Rumex crispus, Sonchus asper, Sonchus oleraceus, Euphorbia terracina, Bromus hordeaceus, Anagallis arvensis, Anthemis cotula, Erodium cicutarium, Lactuca serriola, Melilotus, Rorippa nasturtium-aquaticum, Sisymbrium, Sonchus, Veronica anagallis-aquatica

Samples Used in Description: (n = 3)
rap2752rlv, rap2856rlv, rap2857rlv

Comments:
Salix laevigata and *S. lasiolepis* were sometimes difficult to identify in the field, so their cover estimates were combined into one value in the species list. This association should remain provisional until resampling can occur in which all willow species are clearly identified. The presence of *Quercus agrifolia* seedlings and saplings in two-thirds of the plots suggests a relationship to the *Quercus agrifolia-Salix lasiolepis A*ssociation of the coast live oak alliance.

Phases:
None

COMMON NAME	Red Willow-Arroyo Willow/Douglas Mugwort-California Blackberry/Annual Grass-Herb (Provisional) Woodland/Forest Association
PHYSIOGNOMIC CLASS	Woodland
PHYSIOGNOMIC SUBCLASS	Deciduous woodland
PHYSIOGNOMIC GROUP	Cold-deciduous woodland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural cold-deciduous woodland
FORMATION	Cold-deciduous woodland
ALLIANCE	*Salix laevigata* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	2

ECOLOGICAL REGIONS 261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains

CONSERVATION STATUS RANK G4S4?

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region; however, a comparable association of *S. laevigata-S. lasiolepis/Artemisia douglasiana* is defined in western Riverside and San Diego counties.

Nations:
United States

States or Provinces:
CA

Environmental Description:
The comparable association occurs in southern California within intermittently to seasonally flooded riparian corridors of lower elevations from 100 to 1,540 m on mixed alluvial sediments.

Vegetation Description:
Salix laevigata occurs as a tree overstory dominant, and *S. lasiolepis* occurs as a tree overstory codominant or shrub understory dominant. Other trees infrequently occur at low cover including *Platanus racemosa, Populus fremontii,* and *Quercus agrifolia.* Common understory shrubs include *Baccharis salicifolia*, *Rubus ursinus,* and *Rosa californica.* A wide variety of herb species occupy the understory, with *Artemisia douglasiana* characteristically present. Other herbs often occur including *Mimulus guttatus, Ambrosia psilostachya, Bromus diandrus, B. hordeaceus, Hirschfeldia incana, Lolium multiflorum,* and *Urtica dioica.*

Comments:
The association defined in this Santa Monica Mountains report is comparable to the *S. laevigata-S. lasiolepis/Artemisia douglasiana* Association defined from western Riverside and San Diego counties, and these two could probably collapse into one association.

Salix laevigata-Salix lasiolepis/Baccharis salicifolia Woodland/Forest Association

Red Willow-Arroyo Willow/Mule Fat Woodland/Forest Association
***Salix laevigata* Woodland/Forest Alliance**
Red Willow Woodland/Forest Alliance

Mapping Code: 1412

Local Description

Summary:
This woodland/forest association occurs on gentle to somewhat steep slopes with little influence of aspect (being flat to variable in nature) and at elevations between 73 and 303 m. It is dominated by *Salix laevigata* in the overstory tree layer and *Salix lasiolepis* in the understory tree layer. It has an open cover of *Baccharis salicifolia* in the understory shrub layer and an open cover of various grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Simi Hills Inland, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 73–303 m, mean 241.8 m
Aspect: variable but often flat
Slope: range 2–15 degrees, mean 5.7 degrees
Topography (micro; macro): flat or concave; bottom slopes
Litter Cover: range 55–80%, mean 70%
Small Rock Cover: range 1–30%, mean 12%
Large Rock Cover: range 1–20%, mean 6.3%
Bare Ground: range 10–20%, mean 15%
Parent Material: often depositional, occasionally sedimentary
Soil Texture: coarse loamy sand to fine sandy clay

Vegetation Description:
Stands of *Salix laevigata-Salix lasiolepis/Baccharis salicifolia* Woodland/Forest form an open to intermittent tree layer (14–50%, mean 25.1%) with hardwoods at 5–10 m tall, a sparse to open shrub layer (4–28%, mean 14.3%) at 0–5 m tall, and a sparse to open herbaceous layer (2–18%, mean 9.9%) at 0–1 m tall. Total vegetation cover is 42–51%, mean cover is 47.3%.

In this association, the overstory tree layer is dominated by *Salix laevigata. Salix lasiolepis* is dominant in the understory tree layer. The shrub layer is sparse to open and is dominated by *Baccharis salicifolia*. The herbaceous layer is diverse and often includes *Hirschfeldia incana* and *Artemisia douglasiana.* Other herbs occasionally include *Typha* sp., *Piptatherum miliaceum, Carduus pycnocephalus,* and *Foeniculum vulgare.*

	CAPY2	*Carduus pycnocephalus*	29	0.2	0.2	1			X
	FOVU	*Foeniculum vulgare*	29	0.1	0.2	0.2			X

Other Noteworthy Species:
Dudleya cymosa was found in 1 of 7 surveys of this plant community, which could be one of the rare subspecies such as *D. C.* subsp. *ovatifolia, D. C.* subsp. *marcescens,* or *D. C.* subsp. *agourensis.* Regionally, the park considers these three species as Rare. CNPS ranks them as List 1B, and CNPS R-E-D Code is 3-2-3. Global rank is G5T2 or G5T1, and state rank is S2.2 or S1.2. Federal listing is Threatened, and state listing is none or Rare (CNPS 2005, SAMO 2004).

Nonnative Species:
Hirschfeldia incana, Piptatherum miliaceum, Carduus pycnocephalus, Foeniculum vulgare, Bromus diandrus, Centaurea melitensis, Conyza canadensis, Schinus molle, Brassica nigra, Conium maculatum, Dactylis glomerata, Ricinus communis, Bromus hordeaceus, Marrubium vulgare, Melilotus albus, Sonchus

Samples Used in Description: (n = 7)
AA0582, AA0658, rap1716, rap2491, rap2643, rap2672, rap2685

Comments:
The presence of *Platanus racemosa* in almost half the plots and the ubiquitous presence of *Baccharis salicifolia* suggest an ecological setting similar to the *Platanus racemosa-Quercus agrifolia/Baccharis salicifolia/Artemisia douglasiana* Woodland/Forest Association. The presence of *Salix* species suggests an increase in water availability from the *Platanus*-dominated analog mentioned above. This water may be the result of nonnatural augmentation from runoff from irrigation of private homes, golf courses, wastewater treatment facilities, and so forth.

Phases:
None

COMMON NAME Red Willow-Arroyo Willow/Mule Fat Woodland/Forest Association

SYNONYM	None

Salix lasiolepis Woodland/Forest Alliance

Aroyo Willow Woodland/Forest Alliance

Mapping Code: 1430

Local Description

Summary:
Five stands of this woodland/forest alliance occur usually on relatively flat surfaces with little or no exposure at low elevations between 13 and 251 m. It is dominated by *Salix lasiolepis* as a small tree in the overstory layer. *Baccharis pilularis* and *Malosma laurina* occur often in the understory shrub layer, and *Typha* sp. often occurs in the herbaceous layer.

Distribution:
The five surveys classified to the alliance level occur in the Immediate Coast and Lower Elevation Inland Santa Monica Mountains regions of the study area; however, other association data shows the alliance occurring within all regions of the study area except Eastern Urban.

Environmental Description:
Elevation: range 13–251 m, mean 149.4 m
Aspect: usually none (usually flat), rarely southwest
Slope: range 0–35 degrees, mean 6.8 degrees
Topography (micro; macro): concave or flat; bottom to lower slope
Litter Cover: range 5.0–85%, mean 60.0%
Small Rock Cover: range 1–55%, mean 11.8%
Large Rock Cover: range 0–15%, mean 2.2%
Bare Ground: range 1–60%, mean 18.8%
Parent Material: depositional
Soil Texture: sandy to fine silty clay

Vegetation Description:
Stands of *Salix lasiolepis* Woodland/Forest Alliance form an open to intermittent tree layer (0–65%, mean 31.3%) with hardwoods at 0–10 m tall, an open to intermittent shrub layer (0–58%, mean 12.8%) at 0–10 m tall, and an open to intermittent herbaceous layer (0–37%, mean 6.6%) at 0–2 m tall. Total vegetation cover is 15–78%, mean cover is 49.3%.

In this alliance, the tree layer is dominated by *Salix lasiolepis* as a small tree. Other trees occur infrequently at low cover including *Juglans californica*, *Alnus rhombifolia, Platanus racemesa,* and *Washingtonia*. The shrub layer is open to intermittent and often includes *Baccharis pilularis* and *Malosma laurina.* Occasionally, the shrub layer includes *Myoporum laetum, Ricinus communis,* and *B. salicifolia*. The herbaceous layer is diverse and may be dominated by *Typha* and/or *Scirpus* spp. Other herbs include *Leymus condensatus, Arundo donax,* and many others.

Other Noteworthy Species:

Juglans californica was found in 1 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:

Arundo donax, Myoporum laetum, Ricinus communis, Brassica nigra, Erodium, Foeniculum vulgare, Bromus diandrus, Eucalyptus, Malva parviflora, Nicotiana glauca, Piptatherum miliaceum, Portulaca oleracea

Samples Used in Description: (n = 5)

AA0280cc, AA0579, rap0967, rap1124, rap2749m

Comments:

Five stands were not classified below the alliance level and are represented here (separately from the associations also described). This alliance is typically considered a shrub type in the national vegetation classification, but most stands locally are dominated by trees and warranted description. Most of these five stands sampled locally were associated with higher than normal growing season water as a result of irrigation or runoff. This may have accounted for the relatively high frequency of *Typha* and *Scirpus* spp. in the understory. Identification of some willow tree species was uncertain in a minority of samples but was likely to be of this species.

FORMATION	III.B.2.N.d. Temporarily flooded cold-deciduous shrubland
ALLIANCE	*Salix lasiolepis* Woodland/Forest Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:

This alliance is locally common along creeks, stream terraces, and seeps in Nevada, southwestern Utah, Arizona, New Mexico, east of the Cascade Mountains in Washington, and California.

Nations:

United States

States or Provinces:
AZ, CA, NM, NV, UT, WA

Environmental Description:
Communities within this alliance occupy stream benches and occasionally seeps. They can form stringer communities along drainages with slopes ranging between 1 to 15%. Elevations range between 1,200 m to 2,490 m. Soils are xeric and developed on alluvium. Water tables were rarely reached within the depth of soil pits, and mottles were not evident because of the coarse soil texture.

Vegetation Description:
The tall shrub layer is dominated by *Salix lasiolepis* that forms a dense overstory ranging from 60–100%. *Ribes aureum* and *Rosa woodsii* typically form a low shrub layer near the base of the willows. The undergrowth is typically sparse with *Clematis ligusticifolia* and *Smilacina stellata* present in minor amounts. Bare ground and/or leaf litter from the willow overstory are characteristic of stands within this alliance.

Comments:
In California, this is probably the most common willow alliance below 1,000 m west of the Sierra-Cascade and desert divides. It is particularly common along streams and creeks in the California coast ranges.

Manning and Padgett 1995, NatureServe 2005, Padgett et al. 1989, Sawyer and Keeler-Wolf 1995

Salix lasiolepis/Baccharis salicifolia Woodland/Forest Association

Aroyo Willow/Mule Fat Woodland/Forest Association
***Salix lasiolepis* Woodland/Forest Alliance**
Aroyo Willow Woodland/Forest Alliance

Mapping Code: 1432

Local Description

Summary:
This woodland/forest association occurs on gentle to somewhat steep slopes that are often flat and at elevations between 3 and 413 m. It is dominated by *Salix lasiolepis* in the understory tree layer, *Baccharis salicifolia* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Dry Inland, Western Fog Zone, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 3–413 m, mean 187.2 m
Aspect: often flat, occasionally variable, northeast or northwest
Slope: range 0–15 degrees, mean 5.8 degrees
Topography (micro; macro): variable but often concave; bottom to upper slopes
Litter Cover: range 5–75%, mean 56%
Small Rock Cover: range 1–55%, mean 11.2%
Large Rock Cover: range 0–15%, mean 2.2%
Bare Ground: range 2–60%, mean 19.5%
Parent Material: often depositional, occasionally sedimentary or igneous
Soil Texture: silt to fine sandy clay

Vegetation Description:
Stands of *Salix lasiolepis/Baccharis salicifolia* Woodland/Forest form a sparse to intermittent tree layer (3–65%, mean 37.7%) with hardwoods at 2–10 m tall, a sparse to open shrub layer (0–30%, mean 9%) at 0–5 m tall, and a sparse to open herbaceous layer (0–14%, mean 6%) at 0–1 m tall. Total vegetation cover is 22–78%, mean cover is 50.7%.

In this association, *Salix lasiolepis* dominates in the understory tree layer. *Quercus agrifolia* is occasionally found in low cover in the overstory tree layer. The shrub layer is sparse to open and is dominated by *Baccharis salicifolia*. Occasionally, *Salix lasiolepis, Baccharis pilularis,* and *Ricinus communis* are also included. The herbaceous layer is diverse and occasionally includes *Artemisia douglasiana, Piptatherum miliaceum, Typha, Conium maculatum, Bromus diandrus, Arundo donax, Brassica nigra,* and *Centaurea melitensis.*

Salix lasiolepis/Malosma laurina Woodland/Forest Association

Arroyo Willow/Laurel Sumac Woodland/Forest Association
***Salix lasiolepis* Woodland/Forest Alliance**
Aroyo Willow Woodland/Forest Alliance

Mapping Code: 1433

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes that are often south facing at elevations between 5 and 250 m. *Salix lasiolepis* is dominant in the understory tree and/or shrub layers, and *Malosma laurina* is codominant with the willow in the understory shrub layer. A variety of grasses and forbs, including *Leymus condensatus,* is dominant in the herbaceous layer.

Distribution:
This association is sampled in the Immediate Coast, Lower Elevation Inland Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 5–250 m, mean 99 m
Aspect: often southeast and southwest, occasionally northwest
Slope: range 4–35 degrees, mean 16.3 degrees
Topography (micro; macro): concave or flat; bottom to mid slopes
Litter Cover: range 70–70%, mean 70%
Small Rock Cover: range 1–25%, mean 11.8%
Large Rock Cover: range 0–7%, mean 2.4%
Bare Ground: range 1–30%, mean 14.2%
Parent Material: sedimentary, igneous, or depositional
Soil Texture: moderately fine sandy clay loam to moderately fine silty clay loam

Vegetation Description:
Stands of *Salix lasiolepis/Malosma laurina* Woodland/Forest form a sparse to intermittent tree layer (0–49%, mean 15%) with hardwoods at 0–10 m tall, a sparse to intermittent shrub layer (9–58%, mean 31.2%) at 0–10 m tall, and a sparse to open herbaceous layer (0–15%, mean 3.5%) at 0–1 m tall. Total vegetation cover is 30–62%, mean cover is 49.2%.

In this association, *Salix lasiolepis* is dominant in the understory tree and/or shrub layers. *Juglans californica* is abundant in the understory. The shrub layer is sparse to intermittent and is codominated by *Malosma laurina* as well as the willow. Frequently, *Baccharis pilularis, Baccharis salicifolia, Artemisia californica,* and *Encelia californica* are also included. The herbaceous layer is diverse and occasionally includes *Leymus condensatus, Juncus* sp.*, Rubus ursinus, Centaurea melitensis,* and *Distichlis spicata* in low cover.

Other Noteworthy Species:
Juglans californica was found in 3 of 6 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Centaurea melitensis, Bromus madritensis, Foeniculum vulgare, Arundo donax, Avena fatua, Brassica nigra, Cakile maritima, Carduus pycnocephalus, Cortaderia, Marrubium vulgare, Myoporum laetum, Nicotiana glauca, Pennisetum setaceum, Salsola tragus, Tamarix

Samples Used in Description: (n = 6)
rap0660, rap1017, rap1064, rap1243, rap2263, rap2311

Comments:
The combination of the typically upland xerophytic *Malosma laurina* with the hydrophytic *Salix lasiolepis* is indicative of disturbed alluvial settings on relatively steep slopes (relative to most riparian settings) with southerly aspects. This is often on steep cliffs in slumps or below houses where water availability is higher than normal because of urban runoff.

Schinus molle Woodland/Forest Alliance

Peruvian Peppertree Woodland/Forest Alliance

Mapping Code: 9550

Local Description

Summary:
This woodland/forest alliance occurs on somewhat steep to steep slopes with no or variable exposure at low elevations between 186 and 300 m. It is dominated by the introduced *Schinus molle* in the tree layer. The understory shrub layer has a variety of fast growing species such as *Baccharis pilularis*, and the herbaceous layer is dominated by nonnative grasses and herbs.

Distribution:
This alliance is sampled in the Dry Inland, Lower Elevation Inland Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 186–300 m, mean 254 m
Aspect: none (flat) to variable
Slope: range 15–35 degrees, mean 21.7 degrees
Topography (micro; macro): variable (flat, concave, convex, or undulating); bottom to top
Litter Cover: range 20.0–80%, mean 46.3%
Small Rock Cover: range 0–45%, mean 19.2%
Large Rock Cover: range 0–1%, mean 0.2%
Bare Ground: range 10–54%, mean 29.5%
Parent Material: sedimentary or depositional
Soil Texture: coarse loamy sand to fine sandy clay loam

Vegetation Description:
Stands of *Schinus molle* Woodland/Forest Alliance form an open to intermittent tree layer (3–52%, mean 18.7%) with conifers at 0–10 m tall and hardwoods at 2–10 m tall, an open to intermittent shrub layer (0–36%, mean 10.4%) at 0–5 m tall, and an open to intermittent herbaceous layer (0–40%, mean 10.3%) at 0–1 m tall. Total vegetation cover is 27–55%, mean cover is 39%.

In this alliance, the tree layer is dominated by *Schinus molle* as an invasive species. *Pinus* sp. also has been introduced with low cover. *Quercus agrifolia* is infrequently included in this layer. The shrub layer is usually open and characterized by *Baccharis pilularis* at low cover. A variety of other shrubs is occasionally present at low cover including *Salvia leucophylla, Artemisia californica, Encelia californica, Eriogonum fasciculatum,* and *Malosma laurina*. The herbaceous layer is simple to diverse including many nonnative species such as *Centaurea melitensis, Hirschfeldia incana, Bromus madritensis, Brassica nigra,* and *Carduus pycnocephalus.*

ALLIANCE	*Schinus molle* Woodland/Forest Alliance (Provisional)
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS:	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	An introduced species

Global Description

Distribution:
This alliance is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This is a common introduced tree of central and southern coastal California, originally from the Peruvian Andes. Its seeds occur in fruits that are bird dispersed, and resulting small stands are occasional in south coastal California. It typically forms small open stands with coastal scrub in the more interior portions of the Santa Monica Mountains and Simi Valley areas. Although it is not commonly considered as invasive as the related *Schinus terebinthifolius* (Brazilian peppertree) that is an introduced alliance in Hawaii, Florida, and Texas, it is clearly reproducing and colonizing on its own in the Santa Monica Mountains region.

Umbellularia californica/Ceanothus oliganthus Woodland/Forest Association

California Bay/Hairy Leaf Ceanothus (Provisional) Woodland/Forest Association
***Umbellularia californica* Woodland/Forest Alliance**
California Bay Woodland/Forest Alliance

Mapping Code: 1012

Local Description

Summary:
This woodland/forest association occurs on steep slopes that are northwest or southeast facing (neutral slopes) at low to mid elevations between 499 and 812 m. It is dominated by *Umbellularia californica* in the tree layer, *Ceanothus oliganthus* in the understory shrub layer, and grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 499–812 m, mean 697 m
Aspect: often northwest, occasionally southeast
Slope: range 27–35 degrees, mean 31.2 degrees
Topography (micro; macro): variable; mid to upper slopes
Litter Cover: no data
Small Rock Cover: range 0–20%, mean 10%
Large Rock Cover: range 0–8%, mean 4.3%
Bare Ground: range 0–5%, mean 3.3%
Parent Material: igneous or sedimentary
Soil Texture: medium loam to fine clay

Vegetation Description:
Stands of *Umbellularia californica/Ceanothus oliganthus* Woodland/Forest form an open to intermittent tree layer (22–50%, mean 34.3%) with hardwoods at 2–10 m tall, an open to intermittent shrub layer (20–40%, mean 28.3%) at 0–5 m tall, and a sparse to open herbaceous layer (0–10%, mean 2.5%) at 0–1 m tall. Total vegetation cover is 58–68%, mean cover is 62.8%.

In this association, the overstory and understory tree layers are dominated by *Umbellularia californica*. *Quercus agrifolia* is frequently included in the overstory tree layer at relatively low cover. The shrub layer is sparse to open and is dominated by *Ceanothus oliganthus*, and *Heteromeles arbutifolia* is also characteristically present in low average cover. Occasionally, *Prunus ilicifolia, Lupinus longifolius,* and *Rhus ovata* are also included. The herbaceous layer is simple and includes *Leymus condensatus, Bromus madritensis, Clematis,* and *Pellaea mucronata* at low cover and constancy.

Umbellularia californica-Alnus rhombifolia Woodland/Forest (Provisional) Association

California Bay Woodland/Forest (Provisional) Association
***Umbellularia californica* Woodland/Forest Alliance**
California Bay Woodland/Forest Alliance

Mapping Code: 1013

Local Description

Summary:
This woodland/forest association occurs on relatively gentle slopes with variable aspect at low elevations between 49 and 347 m. It is dominated by *Umbellularia californica*, *Alnus rhombifolia,* and *Platanus racemosa* in the tree layer and *Baccharis salicifolia* in the understory shrub layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 49–347 m, mean 198 m
Aspect: variable
Slope: range 2–2 degrees, mean 2 degrees
Topography (micro; macro): concave; bottom to lower slopes
Litter Cover: no data
Small Rock Cover: range 30–30%, mean 30%
Large Rock Cover: range 15–15%, mean 15%
Bare Ground: range 5–5%, mean 5%
Parent Material: sedimentary
Soil Texture: muck

Vegetation Description:
Stands of *Umbellularia californica-Alnus rhombifolia* Woodland/Forest form an intermittent tree layer (42–43%, mean 42.5%) with conifers at 0–15 m tall and hardwoods at 10–15 m tall, a sparse shrub layer (9%, mean 9%) at 0.5–5 m tall, and a sparse herbaceous layer (9%, mean 9%) at 0–1 m tall. Total vegetation cover is 63–64%, mean cover is 63.5%.

In this association, the overstory tree layer is dominated by *Umbellularia californica*, *Alnus rhombifolia,* and *Platanus racemosa*. *Salix lasiolepis, Quercus agrifolia,* and *Juglans californica* are frequently in the understory tree layer. The shrub layer is sparse and is dominated by *Baccharis salicifolia*. The herbaceous layer is diverse and is dominated by *Arundo donax, Piptatherum miliaceum,* Algae, *Cyperus* sp., *Foeniculum vulgare*, *Bromus diandrus, Equisetum* sp., and *Typha* sp.

Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Arundo donax, Nicotiana glauca, Piptatherum miliaceum, Foeniculum vulgare, Bromus diandrus, Centranthus ruber, Ricinus communis, Acacia redolens, Brassica nigra, Melilotus albus, Pennisetum setaceum, Rumex crispus, Spartium junceum

Samples Used in Description: (n = 2)
rap0386, rap0388

Comments:
This is a locally rare provisional association from one main site location, so it will require further sampling to be validated as an association. It is clearly related to the *Alnus rhombifolia-Platanus racemosa* Association in this report. The presence of significant cover of *Umbellularia californica* suggests a narrow, shaded, and rocky riparian setting.

Phases:
None

Umbellularia californica-Juglans californica/Ceanothus spinosus Woodland/Forest Association

California Bay-California Walnut/Greenbark Ceanothus Woodland/Forest Association
***Umbellularia californica* Woodland/Forest Alliance**
California Bay Woodland/Forest Alliance

Mapping Code: 1011

Local Description

Summary:
This woodland/forest association occurs on moderately steep to steep north-facing slopes at low elevations between 0 and 734 m. It is dominated by *Umbellularia californica* and *Juglans californica* in the tree layer, *Ceanothus spinosus* in the understory shrub layer, and a variety of grasses and forbs in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Immediate Coast region of the study area.

Environmental Description:
Elevation: range 0–734 m, mean 384 m
Aspect: variable but often northeast or northwest
Slope: range 12–40 degrees, mean 26.4 degrees
Topography (micro; macro): variable but often concave; bottom to top slopes
Litter Cover: range 85–85%, mean 85%
Small Rock Cover: range 1–10%, mean 4.5%
Large Rock Cover: range 0–20%, mean 7.3%
Bare Ground: range 1–25%, mean 6.5%
Parent Material: igneous or sedimentary
Soil Texture: medium loam

Vegetation Description:
Stands of *Umbellularia californica-Juglans californica/Ceanothus spinosus* Woodland/Forest form a sparse to intermittent tree layer (8–62%, mean 27.6%) with conifers at 0–10 m tall and hardwoods at 5–15 m tall, a sparse to intermittent shrub layer (1–56%, mean 32.1%) at 0–10 m tall, and a sparse herbaceous layer (0–10%, mean 1.5%) at 0–1 m tall. Total vegetation cover is 35–70%, mean cover is 60.9%.

In this association, the tree layer is dominated by *Umbellularia californica* and *Juglans californica*, and *Quercus agrifolia* is occasionally included in this layer. The shrub layer is sparse to intermittent and is dominated by *Ceanothus spinosus*, and *Heteromeles arbutifolia* is often found in lower cover. Occasionally, *Ceanothus megacarpus, Prunus ilicifolia,* and *Toxicodendron diversilobum* are also included. The herbaceous layer is diverse and occasionally includes *Leymus condensatus, Dryopteris arguta,* and *Piptatherum miliaceum* in low cover.

Comments:
This association with *Umbellularia* as a dominant to codominant with *Juglans* is a common semiriparian association occurring on usually steep northerly facing ravines and upper drainages in the Santa Monica Mountains. This association is similar to the *Juglans californica/Ceanothus spinosus* Association, which is especially found on north-facing slopes that are not particularly riparian.

The overstory cover of *Juglans californica* was variable in the stands because some sampling was done during periods when the leaves of this deciduous species were largely absent.

Phases:
None

Umbellularia californica-Platanus racemosa Woodland/Forest Association

California Bay-California Sycamore Woodland/Forest Association
***Umbellularia californica* Woodland/Forest Alliance**
California Bay Woodland/Forest Alliance

Mapping Code: 1014

Local Description

Summary:
This woodland/forest association occurs on gentle to steep slopes with variable aspects, at low elevations between 183 and 596 m. It is dominated by *Umbellularia californica* and *Platanus racemosa* in the tree layer. *Ceanothus spinosus* is abundant in the understory shrub layer, and a variety of grasses and forbs is in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 183–596 m, mean 418.6 m
Aspect: variable
Slope: range 2–35 degrees, mean 15.7 degrees
Topography (micro; macro): often concave, rarely undulating; bottom to mid slopes
Litter Cover: 60% (one survey)
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: more often sedimentary, occasionally metamorphic or depositional
Soil Texture: medium loam

Vegetation Description:
Stands of *Umbellularia californica-Platanus racemosa* Woodland/Forest form a sparse to continuous tree layer (0–75%, mean 46.6%) with hardwoods at 5–15 m tall, an a sparse to intermittent shrub layer (0–40%, mean 9.5%) at 0–5 m tall, and a sparse herbaceous layer (0–10%, mean 1.6%) at 0–2 m tall. Total vegetation cover is 36–75%, mean cover is 56.7%.

In this association, the tree layer is dominated by *Umbellularia californica* and *Platanus racemosa. Juglans californica* and *Quercus agrifolia* are frequently included in this layer. *Ceanothus spinosus* is abundant in the sparse to intermittent shrub layer. *Heteromeles arbutifolia* is frequently in this layer. Occasionally, *Toxicodendron diversilobum* and *Malosma laurina* are also included. The herbaceous layer is simple and includes *Leymus condensatus* and *Dryopteris arguta*.

Shrub Overstory Vegetation Descriptions

Adenostoma fasciculatum Shrubland Association
Chamise Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 2011

Local Description

Summary:
This shrubland association occurs on flat to steep slopes of variable aspect at low to middle elevations between 38–862 m. It is dominated by *Adenostoma fasciculatum* in the shrub layer with a diverse but low cover herbaceous layer. There are virtually no emergent trees, but occasionally, *Quercus agrifolia, Umbellularia californica,* and *Platanus racemosa* are present.

Distribution:
This association is sampled in the Upper and Lower Elevation Santa Monica Mountains, Western Fog Zone, Simi Hills Inland, Dry Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 38–862 m, mean 420.2 m
Aspect: variable
Slope: range 0–45 degrees, mean 23.3 degrees
Topography (micro;macro): variable; lower slope to ridge
Litter Cover: range 0–60%, mean 25.2%
Small Rock Cover: range 1–68%, mean 27.3%
Large Rock Cover: range 0–55%, mean 4.8%
Bare Ground: range 0–50%, mean 25.6%
Parent Material: sedimentary or igneous
Soil Texture: coarse loamy sand to fine clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum* Shrubland form an open to intermittent shrub layer (12–65%, mean 37.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–15%, mean 2.4%) at 0–5 m tall. Trees are occasionally emergent (0–7% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 15–65%, mean cover is 40.1%.

In this association, the shrub layer is characterized by an abundance of *Adenostoma fasciculatum*. *Salvia mellifera* and *Malosma laurina* are usually included in this layer. The tree layer is emergent and open and may rarely include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Bromus madritensis, Nassella lepida, Centaurea melitensis, Bromus diandrus,* or *Hemizonia fasciculata*.

Comments:
Throughout much of California, there are stands strongly dominated by *Adenostoma fasciculatum* with little else to characterize them. This association is the local SAMO expression of this strongly dominated *A. fasciculatum* vegetation. Clearly, there are some associated species not to be expected in other parts of the state, but none of them occur frequently enough to be

considered characteristic. Thus, this is called the *A. fasciculatum* Shrubland Association although it may be ecologically and biotically somewhat different than other similar associations defined elsewhere in the state.

Phases:
None

COMMON NAME	Chamise Shrubland Association

ALLIANCE	*Adenostoma fasciculatum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. However, several other chamise associations have been defined from California including San Diego County (Evens and San 2005), western Riverside County (Klein, Evens, Keeler-Wolf and Hickson 2005), and mafic soils type from the peninsular ranges (Gordon & White 1994). Several of these may be so similar to be considered synonymous.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
The chamise alliance is the most widespread chaparral vegetation in California and ranges from Shasta County in the north to northwestern Baja California, Mexico.

Adenostoma fasciculatum-Ceanothus megacarpus Shrubland Association

Chamise-Big Pod Ceanothus Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 2019

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low to mid elevations between 130–810 m. It is dominated by *Adenostoma fasciculatum* in the shrub layer with lower cover of *Ceanothus megacarpus.* It has no significant herbaceous layer. The emergent tree layer is generally nonexistent but may include occasional emergent *Quercus agrifolia*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Western Fog Zone, Immediate Coast, Dry Inland, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 130–810 m, mean 426.4 m
Aspect: variable
Slope: range 2–35 degrees, mean 23 degrees
Topography (micro; macro): undulating or convex; mid to upper slope
Litter Cover: range 8–50%, mean 23%
Small Rock Cover: range 0–55%, mean 25%
Large Rock Cover: range 0–11%, mean 3.1%
Bare Ground: range 0–58%, mean 30.5%
Parent Material: sedimentary or igneous
Soil Texture: coarse loamy sand to moderately fine clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Ceanothus megacarpus* Shrubland form an open to intermittent shrub layer (23–60%, mean 39.1%). Shrubs occur in two different strata, with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–10%, mean 1.2%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 30—60%, mean cover is 40.3%.

In this association, the shrub layer is characterized by abundant *Adenostoma fasciculatum* with *Ceanothus megacarpus, Malosma laurina,* and *Salvia mellifera* also present. *Yucca whipplei* is often present, and *Lotus scoparius* and *Heteromeles arbutifolia* are occasionally included in this layer. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Centaurea melitensis, Nassella lepida, Bromus madritensis,* and *Pellaea mucronata*.

***Adenostoma fasciculatum-Ceanothus megacarpus* Association**

	HASQ2	*Hazardia squarrosa*	21	0.1	0.2	2.0			

Other Noteworthy Species:
Lepechinia fragrans was found in 3 of 42 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Bromus madritensis, Hirschfeldia incana, Bromus hordeaceus, Avena, Bromus diandrus, Anagallis arvensis, Avena fatua, Carduus pycnocephalus, Schinus molle

Samples Used in Description: (n = 42)
AA0024cc, AA0289cc, AA0335, AA0521, AA0668, AA0827, AA0887, AA1039, AA1139, AA1202, rap0005m, rap0020, rap0107, rap0110, rap0131m, rap0141, rap0180, rap0208, rap0286, rap0313, rap0375, rap0414, rap0423m, rap0525, rap0530, rap0544, rap0595, rap0597, rap0799, rap1290, rap1487, rap1702m, rap1735, rap1781, rap2121, rap2243, rap2360, rap2401, rap2474, rap2485, rap2715, rap2788

Comments:
This is an abundant association in the study area and is an interesting one from the standpoint of monitoring. In general, *Ceanothus megacarpus* appears to have become more abundant in the Santa Monica Mountains over the past 60–70 years, while *Adenostoma fasciculatum* has declined (R. Taylor 2004 personal communication). It is in this association of the *Adenostoma fasciculatum* Alliance where one might expect to observe shifts in relative cover and abundance of these two shrubs. Monitoring of several of the 42 samples in these stands through fire events may help clarify the long-term trends of these two common shrub species.

Phases:
None

Adenostoma fasciculatum-Eriogonum fasciculatum Shrubland Association

Chamise-California Buckwheat Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 2017

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 150–718 m. It is dominated by *Adenostoma fasciculatum* with lower cover of *Eriogonum fasciculatum* in the shrub layer and a low cover of mostly nonnative grasses and forbs in the herbaceous layer. The emergent tree layer is generally nonexistent.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 150–718 m, mean 345.5 m
Aspect: variable
Slope: range 4–35 degrees, mean 21.4 degrees
Topography (micro; macro): undulating; lower to upper slope
Litter Cover: range 10–25%, mean 18.3%
Small Rock Cover: range 10–45%, mean 20.7%
Large Rock Cover: range 0–50%, mean 8.1%
Bare Ground: range 10–54%, mean 31.1%
Parent Material: igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Eriogonum fasciculatum* Shrubland form an open to intermittent shrub layer (8–49%, mean 31.1%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–30%, mean 6.7%) at 0–1 m tall. Trees are occasionally emergent (0–1% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 21–51%, mean cover is 36.9%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum, Eriogonum fasciculatum,* and *Lotus scoparius. Salvia mellifera, Malosma laurina,* and *Yucca whipplei* are usually included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and often includes *Centaurea melitensis* and *Bromus diandrus.* Other herbs sometimes include *Bromus hordeaceus, Brassica nigra, Bromus madritensis,* and *Chlorogalum pomeridianum*.

Comments:
The presence of living or dead *Lotus scoparius* in most of the stands of this association suggests it is a seral association of the *Adenostoma fasciculatum* Alliance. In general, most of these stands appear to have been disturbed by fire within the past 10 years. Over time, these stands may be colonized by *C. crassifolius, C. megacarpus,* or *C. cuneatus* based on location, and the canopy may close, largely excluding *E. fasciculatum*. The two phases identified suggest a more disturbed seral chaparral with annual grasses (perhaps more frequent fires or poor germination of obligate seeding chaparral species) and a phase with better germination of seral fire following shrubs such as *Dendromecon* and *Lotus scoparius*.

Phases:
Adenostoma fasciculatum-Eriogonum fasciculatum/Annual Grass-Herb (Chamise-California Buckwheat/Annual Grass-Herb) Phase [2017]
Adenostoma fasciculatum-Lotus scoparius-Dendromecon rigida (Chamise-Deerweed-Bush Poppy) Phase [7012]

COMMON NAME	Chamise-California Buckwheat Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Adenostoma fasciculatum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains region as well as from western Riverside County (Klein and Evens 2005).

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Stands of this association sampled in western Riverside County also have *Salvia mellifera*, *Arctostaphylos glauca*, *Encelia farinosa,* and *Rhus ovata* in the shrub layer. A similar association, the *Adenostoma fasciculatum-Eriogonum fasciculatum-Salvia apiana* Association, is also known from western Riverside County.

Klein and Evens 2005

Adenostoma fasciculatum-Malosma laurina Shrubland Association

Chamise-Laurel Sumac Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 2013

Local Description

Summary:
This shrubland association occurs on moderate to steep slopes of variable aspect at low to mid elevations between 111–991 m. It is dominated by *Adenostoma fasciculatum* and subdominated by *Malosma laurina* in the shrub layer. The herbaceous layer is sparse and composed primarily of introduced annual species. The emergent tree layer includes *Quercus agrifolia* in 20% of the samples.

Distribution:
This association is sampled in the Immediate Coast, Upper Elevation Santa Monica Mountains, Simi Hills Inland, Lower Elevation Inland Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 111–991 m, mean 445.1 m
Aspect: variable
Slope: range 6–35 degrees, mean 25.3 degrees
Topography (micro; macro): undulating; mid to upper slope
Litter Cover: range 15–25%, mean 17.5%
Small Rock Cover: range 0–75%, mean 18.2%
Large Rock Cover: range 0–90%, mean 14.7%
Bare Ground: range 0–60%, mean 29.3%
Parent Material: sedimentary
Soil Texture: coarse loamy sand to moderately fine sandy clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Malosma laurina* Shrubland form an open to intermittent shrub layer (8–55%, mean 35.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–9%, mean 1.2%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 8–55%, mean cover is 36.2%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum, Malosma laurina,* and *Salvia mellifera*. *Yucca whipplei* is often present, and *Eriogonum fasciculatum* is occasionally included in this layer. The tree layer is emergent and open and sometimes includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Bromus madritensis, Hirschfeldia incana, Centaurea melitensis, Bromus diandrus,* and *Brassica nigra*.

Other Noteworthy Species:
Leptodactylon californicum was found in 2 of 25 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G5T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Bromus madritensis, Avena, Hirschfeldia incana, Centaurea melitensis, Brassica nigra, Bromus diandrus, Bromus hordeaceus, Pennisetum setaceum, Erodium, Silene gallica

Samples Used in Description: (n = 25)

Comments:
This is a relatively common association in the study area. The presence of *Malosma laurina* with chamise indicates relatively warm and dry conditions. Although *Adenostoma fasciculatum* is typically dominant, averaging about twice the cover of *M. laurina*, occasionally *M. laurina* may codominate.

Phases:
None

Adenostoma fasciculatum-Malosma laurina-Eriodictyon crassifolium/ Annual Grass-Herb Shrubland Association

Chamise-Laurel Sumac-Yerba Santa Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 7018

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 162–657 m. It is dominated by *Adenostoma fasciculatum* and subdominated by *Malosma laurina* in the shrub layer and scattered native and nonnative species in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia* in about one-third of the samples.

Distribution:
This association is sampled in the Immediate Coast and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 162–657 m, mean 526 m
Aspect: variable
Slope: range 2–42 degrees, mean 20.3 degrees
Topography (micro; macro): flat, undulating, convex, or concave; lower slope to ridge
Litter Cover: range 7–55%, mean 26.2%
Small Rock Cover: range 2–35%, mean 15%
Large Rock Cover: range 0–60%, mean 17.8%
Bare Ground: range 8–70%, mean 24.9%
Parent Material: sedimentary
Soil Texture: medium loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Malosma laurina-Eriodyction crassifolium*/Annual Grass-Herb Shrubland form an open to intermittent shrub layer (4–42%, mean 21.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (2–32%, mean 13.6%) at 0–1 m tall. Trees are occasionally emergent (0–15% cover, mean 1.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 25–52%, mean cover is 36.8%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum, Eriodictyon crassifolium, Malosma laurina,* and *Salvia mellifera*. *Eriogonum fasciculatum, Ceanothus crassifolius,* and *Lotus scoparius* are usually included in this layer. The tree layer is emergent and open and sometimes includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and often includes *Bromus madritensis* and *Centaurea melitensis.* Other herbs sometimes include *Bromus diandrus, Filago californica, Hirschfeldia incana,* and *Avena barbata*.

Other Noteworthy Species:

Hemizonia minthornii was found in 4 of 16 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-2-3. Global rank is G2 , and state rank is S2.2 (CNPS 2005). Federal listing is Species of Concern, and state listing is Rare (SAMO 2004).

Nonnative Species:

Centaurea melitensis, Bromus madritensis, Hirschfeldia incana, Bromus diandrus, Brassica nigra, Bromus hordeaceus, Avena, Avena barbata, Erodium cicutarium, Avena fatua, Anagallis arvensis, Vicia villosa, Carduus pycnocephalus, Lamarckia aurea, Nicotiana glauca, Silene gallica

Samples Used in Description: (n = 16)
AA0195cc, AA0196cc, AA0197cc, AA0198cc, AA0264cc, rap1548, rap1603, rap1607, rap1609, rap1610, rap1994, rap2208, rap2372, rap2409, rap2410, rap2411

Comments:
The presence of *Eriodictyon crassifolium* suggests a seral setting in these stands. This is strengthened by the presence of other common short-lived perennial species such as *Lotus scoparius, Hazardia squarrosa*, and numerous annual nonnative species. However, it may persist for longer periods in rocky areas with thin soils. This vegetation type is clearly related to the *Adenostoma fasciculatum-Malosma laurina* Association and may ultimately be considered a broad seral phase of it.

Phases:
None

Adenostoma fasciculatum-Mimulus aurantiacus Shrubland Association

Chamise-Bush Monkey Flower Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 7013

Local Description

Summary:
This shrubland association occurs on steep to very steep northeast-facing slopes at low elevations between 277–488 m. It is dominated by *Adenostoma fasciculatum* with lesser cover of *Mimulus aurantiacus* in the shrub layer with little distinguishing the herbaceous layer. The emergent tree layer includes *Quercus agrifolia*.

Distribution:
This association is sampled in the Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 277–488 m, mean 351.1 m
Aspect: northeast
Slope: range 30–60 degrees, mean 37.1 degrees
Topography (micro; macro): undulating, flat, convex, or concave; lower to ridge top
Litter Cover: range 20–60%, mean 41.7%
Small Rock Cover: range 6–35%, mean 21.5%
Large Rock Cover: range 0–1%, mean 0.5%
Bare Ground: range 20–42%, mean 30.5%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine clay loam or sandy clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Mimulus aurantiacus* Shrubland form an intermittent shrub layer (40–48%, mean 43.9%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–4%, mean 1%) at 0–1 m tall. Trees are occasionally emergent (0–10% cover, mean 1.7%) with hardwoods at 0–10 m tall. Total vegetation cover is 40–52%, mean cover is 46.1%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum* and *Mimulus aurantiacus. Heteromeles arbutifolia, Salvia mellifera,* and *Malosma laurina* are usually included in this layer. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and occasionally includes *Bromus madritensis.* Other herbs may include *Piptatherum miliaceum, Pentagramma triangularis, Nassella lepida,* and *Marah macrocarpus.*

Samples Used in Description: (n = 7)
rap1912, rap1914, rap2024, rap2071, rap2376, rap2484, rap2827

Comments:
The presence of *Mimulus aurantiacus* as a constant in this association suggests a more coastal or semisheltered setting for this association of the chamise alliance. The *M. aurantiacus* Association of the chamise alliance tends to occur in somewhat rocky, steep areas but typically not as xeric as many other chamise associations. All local aspects are northeast facing, and this association appears to be most common in areas within the summer fog zone.

Phases:
None

FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Adenostoma fasciculatum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains and from Marin County. Information about its global distribution is not available without additional inventory; however, it likely occurs elsewhere in the coastal mountains of California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
In Marin County (Keeler-Wolf et al. 2003), this association is found on the upper one-third of rocky, 16–30 degree angle, south-facing slopes. Soil textures range from medium loam to moderately coarse sandy loam of sandstone origin. Most stands are above the average summer fog layer.

Vegetation Description:
In Marin County (Keeler-Wolf et al. 2003) stands of the *Adenostoma fasciculatum-Mimulus aurantiacus Shrubland* Association are dominated by *Adenostoma fasciculatum*. *Mimulus aurantiacus covers 1 to 20% of the stand.* Also common in this association are the small nonnative grasses *Aira caryophyllea* and *Gastridium ventricosum.* Other shrubs and understory herbs vary but may include *Melica californica, Hypericum concinnum, Nassella pulchra, Nassella lepida, Avena barbata, Zigadenus fremontii, Chlorogalum pomeridianum, Pleuropogon californicus, Bromus madritensis rubens, Cynosurus echinatus,* and *Baccharis pilularis. Umbellularia californica* may also be present.

Comments:
The association named *Adenostoma fasciculatum-Mimulus aurantiacus* was first described from the outer coast ranges of northern California in Marin County (Keeler-Wolf et al. 2003). Although it differs to some degree in the species composition from the Santa Monica Mountains version, it is essentially similar in that it occurs near or in the coastal fog zone within only one mile or two of the ocean. It stands to reason that the more northerly expression of this association is more restricted to south-facing slopes and in otherwise relatively more xeric settings than the southern California expression where there is less rainfall and warmer temperatures.

Keeler-Wolf et al. 2003

Adenostoma fasciculatum-Salvia leucophylla Shrubland Association

Chamise-Purple Sage (Provisional) Shrubland Association
***Adenostoma fasciculatum* Shrubland Alliance**
Chamise Shrubland Alliance

Mapping Code: 2018

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes at low elevations between 567 and 631 m. It is codominated by *Adenostoma fasciculatum* and *Salvia leucophylla* in the shrub layer, and a variety of other coastal sage and chaparral shrubs are often present at low cover. The herbaceous layer is variable and may be dominated by grasses or herbs such as *Avena* sp., *Centaurea melitensis,* and/or *Hemizonia fasciculata*. The tree layer is not recorded.

Distribution:
This association is sampled in the Simi Hills Inland region of the study area.

Environmental Description:
Elevation: range 567–631 m, mean 614 m
Aspect: northeast and southwest
Slope: range 15–35 degrees, mean 25.3 degrees
Topography (micro; macro): usually flat, sometimes convex; mid to upper slopes to ridgetop
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: no data
Soil Texture: no data

Vegetation Description:
Stands of *Adenostoma fasciculatum-Salvia leucophylla* Shrubland form intermittent shrub layer (35–48%, mean 43%). Shrubs commonly occur in two different strata, with low shrubs at 0.5–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–15%, mean 5.5%) at 0.01–1 m tall. The tree layer is not recorded. Total vegetation cover is 48.–50%, mean cover is 48.5%.

In this association, shrub layer is intermittent and codominated by *Adenostoma fasciculatum* and *Salvia leucophylla*. A variety of other coastal sage and chaparral shrubs is often present at low cover including *Heteromeles arbutifolia*, *Salvia mellifera, Ceanothus crassifolius*, and *Malacothamnus fasciculatus.* The herbaceous layer is variable and may be dominated by *Centaurea melitensis, Avena* sp., and/or *Hemizonia fasciculata*. Other herbs at low cover often include *Marah macrocarpus* and *Leymus condensatus.* The tree layer is absent.

Adenostoma fasciculatum-Adenostoma sparsifolium-Ceanothus crassifolius Shrubland Association

Chamise-Redshank-Hoary Leaf Ceanothus Shrubland Association
***Adenostoma fasciculatum-Adenostoma sparsifolium* Shrubland Alliance**
Chamise-Redshank Shrubland Alliance

Mapping Code: 2042

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low to mid elevations between 320–888 m. It is dominated by *Adenostoma fasciculatum, Adenostoma sparsifolium, and Ceanothus crassifolius* in the shrub layer with little cover in the herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 320–888 m, mean 705.8 m
Aspect: variable
Slope: range 2–35 degrees, mean 20.3 degrees
Topography (micro; macro): undulating, convex, or flat; lower slope to ridgetop
Litter Cover: range 60–80%, mean 70%
Small Rock Cover: range 5–40%, mean 16%
Large Rock Cover: range 0–5%, mean 1.8%
Bare Ground: range 10–38%, mean 21.7%
Parent Material: igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Adenostoma sparsifolium-Ceanothus crassifolius* Shrubland form an open to intermittent shrub layer (21–58%, mean 42.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–31%, mean 5.5%) at 0–0.5 m tall. Trees are not present. Total vegetation cover is 42–58%, mean cover is 48%.

In this association, the shrub layer is characterized by *Adenostoma sparsifolium, Ceanothus crassifolius,* and *Adenostoma fasciculatum*. *Yucca whipplei* and *Rhus ovata* are occasionally included in this layer. The tree layer is absent. The herbaceous layer is diverse and may include *Bromus hordeaceus, Centaurea melitensis,* and *Avena* sp.

Comments:
This association is characterized by a codominance of the three nominate species. Although *Ceanothus crassifolius* is a widespread chaparral species forming its own alliance in many parts of southern coastal California, it is not known to occur with redshank in combination with chamise anywhere outside of the Santa Monica Mountains.

Phases:
None

Adenostoma fasciculatum-Arctostaphylos glandulosa Shrubland Association

Chamise-Eastwood Manzanita Shrubland Association
***Adenostoma fasciculatum-Arctostaphylos glandulosa* Shrubland Alliance**
Chamise-Eastwood Manzanita Shrubland Alliance

Mapping Code: 2021

Local Description

Summary:
This shrubland association occurs on moderately steep to steep northeast- and northwest-facing slopes at low to mid elevations between 207–781 m. It is dominated by *Adenostoma fasciculatum* and *Arctostaphylos glandulosa* in the shrub layer and in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 207–781 m, mean 536.9 m
Aspect: northeast and northwest
Slope: range 7–38 degrees, mean 21.9 degrees
Topography (micro; macro): undulating or convex; lower slope to ridgetop
Litter Cover: range 15–35%, mean 25%
Small Rock Cover: range 1–45%, mean 16.3%
Large Rock Cover: range 0–25%, mean 9.1%
Bare Ground: range 5–40%, mean 24.8%
Parent Material: sedimentary or quaternary
Soil Texture: coarse to very fine loamy sand

Vegetation Description:
Stands of *Adenostoma fasciculatum-Arctostaphylos glandulosa* Shrubland form an open to continuous shrub layer (30–70%, mean 49.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–2%, mean 0.1%) at 0–0.5 m tall. Trees are occasionally emergent (0–5% cover, mean 0.7%) with hardwoods at 0–15 m tall. Total vegetation cover is 31–70%, mean cover is 50.3%.

In this association, the shrub layer is characterized by abundant cover of *Adenostoma fasciculatum* and *Arctostaphylos glandulosa*. *Malosma laurina* and *Heteromeles arbutifolia* are usually included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Piptatherum miliaceum, Bromus diandrus, Bromus madritensis,* or *Marah macrocarpus*.

Comments:
This is an upper elevation chaparral found on the upper slopes of the Santa Monica Mountains and the Simi Hills. It typically occurs on upper ridges and slopes usually above 600 m on northerly facing slopes. In addition to the main manifestation of codominant *A. fasciculatum* and *A. glandulosa*, another phase with a constant presence of *Ceanothus megacarpus* has been identified.

Phases:
Adenostoma fasciculatum-Arctostaphylos glandulosa (Chamise-Eastwood Manzanita) Phase [2021]
Adenostoma fasciculatum-Ceanothus megacarpus-Arctostaphylos glandulosa (Chamise-Big Pod Ceanothus-Eastwood Manzanita) Phase [7017]

COMMON NAME	Chamise-Eastwood Manzanita Shrubland Association
SYNONYM	*Arctostaphylos glandulosa* Alliance (Reid et al. 1999)
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Adenostoma fasciculatum-Arctostaphylos glandulosa* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains as well as several other mountain ranges of southern California including the San Gabriel, San Bernardino, San Jacinto, and peninsular ranges.

Nations:
United States

States or Provinces:
CA

Environmental Description:
The *Adenostoma fasciculatum-Arctostaphylos glandulosa* Association of California is found on north-facing slopes, outcrops, and ridges on shallow soils. Occurrences range in elevation from 300 to 2,200 m. This alliance often follows disturbance, growing on sites that have been burned, logged, or otherwise disturbed.

Vegetation Description:
In western Riverside County, the *Adenostoma fasciculatum-Arctostaphylos glandulosa* Association has *Adenostoma fasciculatum* and *Arctostaphylos glandulosa* consistently present, and both species are usually codominant, though sometimes *Arctostaphylos glandulosa* may be subdominant to *Adenostoma fasciculatum*. Other chaparral shrubs often intermix as subdominants including *Quercus berberidifolia, Heteromeles arbutifolia,* and *Garrya flavescens*.

Comments:
Very similar stands of this association occur throughout many of the mountain ranges of southern coastal California.

Borchert et al. 2004, Gordon and White 1994, Klein and Evens 2005, Reid et al. 1999

Adenostoma fasciculatum-Arctostaphylos glauca Shrubland Association

Chamise-Big Berry Manzanita (Provisional) Shrubland Association
***Adenostoma fasciculatum-Arctostaphylos glauca* Shrubland Alliance**
Chamise-Big Berry Manzanita Shrubland Alliance

Mapping Code: 2531

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northeast- and northwest-facing slopes at low elevations between 367–664 m. It is dominated by *Adenostoma fasciculatum* and *Arctostaphylos glauca* in the shrub layer with an insignificant herbaceous layer.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 367–664 m, mean 445.8 m
Aspect: northeast and northwest
Slope: range 20–35 degrees, mean 29 degrees
Topography (micro; macro): flat, undulating, or concave; mid slope to ridgetop
Litter Cover: range 30–30%, mean 30%
Small Rock Cover: range 2–50%, mean 19.7%
Large Rock Cover: range 0–3%, mean 1%
Bare Ground: range 8–45%, mean 27%
Parent Material: igneous
Soil Texture: coarse loamy sand

Vegetation Description:
Stands of *Adenostoma fasciculatum-Arctostaphylos glauca* Shrubland form an intermittent shrub layer (40–60%, mean 49.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is bare. Trees are not present. Total vegetation cover is 40–60%, mean cover is 49.5%.

In this association, the shrub layer is characterized by *Malosma laurina, Ceanothus megacarpus*, *Adenostoma fasciculatum,* and *Arctostaphylos glauca*. *Salvia mellifera, Cercocarpus betuloides,* and *Heteromeles arbutifolia* are occasionally included in this layer. The tree layer is absent. The herbaceous layer is simple and sometimes contains *Bromus madritensis* and *Centaurea melitensis.*

None

Nonnative Species:
Bromus madritensis, Centaurea melitensis

Samples Used in Description: (n = 4)
rap0378, rap0379, rap0412, rap2921

Comments:
This association occurs locally in the higher and more inland continental portions of the study area. *A. glauca* is a xerophytic manzanita, and it commonly codominates with chamise in many of the hotter, drier chaparral stands throughout central and southern California including the western borders of the Mojave and Sonoran deserts.

Phases:
None

COMMON NAME	Chamise-Big Berry Manzanita Shrubland Association
SYNONYM	*Arctostaphylos glauca* Shrubland Alliance (Reid et al. 1999)
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland

PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Adenostoma fasciculatum-Arctostaphylos glauca* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S4

Global Description

Distribution:
This is a common association in the southern and central coastal California area.

Nations:
United States, Mexico (Baja)

States or Provinces:
CA

Environmental Description:
Stands are found at elevations between 300 and 1,000 m. Aspect is more often northerly, less often southerly. Slopes are usually moderate to steep with variable topography. Parent material is varied including granitic metamorphic, sedimentary, and igneous. Soil texture is also varied from sandy loam and sand to clay loam.

Vegetation Description:
In the *Adenostoma fasciculatum-Arctostaphylos glauca* Association, the two species are consistently codominant in the intermittent to dense shrub overstory. A variety of other chaparral species intermixes as subdominants shrubs (e.g., *Garrya flavescens, Keckiella antirrhinoides, Prunus ilicifolia, Heteromeles arbutifolia*).

Comments:
This is a common association in the southern and central coastal California area. It has been reported in San Diego, Riverside, Los Angeles, Santa Barbara, Ventura, San Benito, Monterey, San Luis Obispo, and Fresno counties. Its presence reflects somewhat drier and warmer conditions than the *Adenostoma fasciculatum-Arctostaphylos glandulosa* Association of the *A. fasciculatum–A. glandulosa* Alliance. *Arctostaphylos glauca* is an obligate seeder as opposed to *A. glandulosa*, which is a resprouting species. Similar stands occur as far north as Alameda County in the central coast ranges, though they have not been adequately described (Keeler-Wolf 2005 personal observation).

Evens and San 2005, Evens et al. 2005, Gordon and White 1994, Klein and Evens 2005, Reid 1999, Sawyer and Keeler-Wolf 1995

Adenostoma fasciculatum-Ceanothus crassifolius-Malosma laurina Shrubland Association

Chamise-Hoary Leaf Ceanothus-Laurel sumac Shrubland Association
***Adenostoma fasciculatum-Ceanothus crassifolius* Shrubland Alliance**
Chamise-Hoary Leaf Ceanothus Shrubland Alliance

Mapping Code: 2572

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes of variable aspect at low to mid elevations between 17–821 m. It is dominated by both *Adenostoma fasciculatum* and *Ceanothus crassifolius* in the shrub layer, although *C. crassifolius* is typically somewhat higher cover. The herbaceous layer is sparse except for occasional vines of *Marah macrocarpa,* which may sprawl over the shrubs. Trees are generally absent.

Distribution:
This association is sampled in the Simi Hills Inland, Upper Elevation Santa Monica Mountains, Dry Inland, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 17–821 m, mean 467.5 m
Aspect: variable
Slope: range 15–35 degrees, mean 27.1 degrees
Topography (micro; macro): undulating, flat, concave, or convex; lower to upper slope
Litter Cover: range 20–85%, mean 37.9%
Small Rock Cover: range 1–40%, mean 13.2%
Large Rock Cover: range 0–15%, mean 1.9%
Bare Ground: range 0–60%, mean 29.4%
Parent Material: predominantly sedimentary, some igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Ceanothus crassifolius-Malosma laurina* Shrubland form an open to intermittent shrub layer (22–60%, mean 45.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–10 m tall. The herbaceous layer is open (0–13%, mean 2%) at 0–1 m tall. Trees are occasionally emergent (0–5% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 32–60%, mean cover is 48.3%.

In this association, the shrub layer is characterized by *Ceanothus crassifolius, Adenostoma fasciculatum, Salvia mellifera*, and *Malosma laurina*. *Heteromeles arbutifolia, Rhus ovata,* and *Yucca whipplei* are occasionally included in this layer. The tree layer is emergent and open and may rarely include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and may include *Marah macrocarpus, Bromus madritensis, Phacelia cicutaria*, and *Centaurea melitensis.*

Other Noteworthy Species:
Astragalus brauntonii was found in 1 of 43 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 3-3-3. Global rank is G2, and state rank is S2.1 (CNPS 2005). Federal listing is Endangered, and state listing is none (SAMO 2004).

Hemizonia minthornii was found in 1of 43 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.2 (CNPS 2005). Federal listing is Species of Concern, and state listing is Rare (SAMO 2004).

Nonnative Species:
Bromus madritensis, Centaurea melitensis, Avena, Brassica nigra, Bromus diandrus, Hirschfeldia incana, Foeniculum vulgare, Nicotiana glauca, Avena fatua, Bromus hordeaceus, Bromus madritensis subsp. *rubens, Centaurea solstitialis, Marrubium vulgare, Melilotus indicus, Stellaria media*

Samples Used in Description: (n = 43)
AA0029cc, AA0187cc, AA0188cc, AA0192cc, AA0194cc, AA0200cc, AA0296cc, AA0867, AA0939, AA0967, AA1081, AA1104, rap0399, rap0400, rap0492, rap0781, rap1541, rap1542, rap1545m, rap1611, rap1679, rap1681, rap1683, rap1693, rap1698, rap1779, rap1795, rap1796, rap2039m, rap2043, rap2054, rap2091, rap2092, rap2147, rap2149, rap2172, rap2178, rap2179, rap2289, rap2290, rap2333, rap2336, rap2920

Comments:
This association is common in the Simi Hills and at the upper elevation, central portions of the Santa Monica Mountains. The presence of the frost-sensitive *Malosma laurina* in more than 75% of the samples suggests that this is a relatively warm temperate association of the mixed *Adenostoma fasciculatum-Ceanothus crassifolius* Alliance.

Phases:
None

Adenostoma fasciculatum-Ceanothus cuneatus-Salvia mellifera-Malosma laurina Shrubland Association

Chamise-Wedge Leaf Ceanothus-Black Sage-Laurel Sumac Shrubland Association
***Adenostoma fasciculatum-Ceanothus cuneatus* Shrubland Alliance**
Chamise-Wedge Leaf Ceanothus Shrubland Alliance

Mapping Code: 2511

Local Description

Summary:
This shrubland association occurs on moderately steep to very steep slopes of variable aspect at low elevations between 109–521 m. It is dominated by *Adenostoma fasciculatum* and *Ceanothus cuneatus* with *Salvia mellifera* and *Malosma laurina* as constant subdominants in the shrub layer. It has a low cover of mostly nonnative exotics in the herbaceous layer. The emergent tree layer may include *Quercus agrifolia*.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 109–521 m, mean 306 m
Aspect: variable
Slope: range 9–55 degrees, mean 28.8 degrees
Topography (micro; macro): undulating or convex; lower slope to ridge
Litter Cover: range 15–25%, mean 20%
Small Rock Cover: range 5–40%, mean 22%
Large Rock Cover: range 0–3%, mean 1.6%
Bare Ground: range 15–44%, mean 33.4%
Parent Material: predominantly igneous, some sedimentary
Soil Texture: moderately fine sandy or silty clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Ceanothus cuneatus-Salvia mellifera-Malosma laurina* Shrubland form an open to intermittent shrub layer (18–52%, mean 40.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–15%, mean 3.4%) at 0–0.5 m tall. Trees are occasionally emergent (0–3% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 22–52%, mean cover is 44%.

In this association, the shrub layer is characterized by *Ceanothus cuneatus, Adenostoma fasciculatum,* and *Eriogonum fasciculatum*. *Salvia mellifera, Malosma laurina, Rhus ovata,* and *Yucca whipplei* are usually included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and occasionally includes *Centaurea melitensis* and *Bromus madritensis.* Other herbs sometimes include *Dudleya pulverulenta, Chlorogalum pomeridianum,* and *Hemizonia fasciculata*.

Comments:
This association is the only expression of this widespread California alliance locally. It occurs sporadically mostly in the central portion of the Santa Monica Mountains at mid elevations. It remains to be seen how closely related it is to other stands of this alliance reported from other parts of southern California (Gordon and White 1994, Klein and Evens 2005, Borchert et al. 2004).

Adenostoma fasciculatum-Salvia mellifera Shrubland Association

Chamise-Black Sage Shrubland Association
***Adenostoma fasciculatum-Salvia mellifera* Shrubland Alliance**
Chamise-Black Sage Shrubland Alliance

Mapping Code: 2036

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southeast- to northwest-facing slopes at low elevations between 114–510 m. It is dominated by *Adenostoma fasciculatum* and *Salvia mellifera* in the shrub layer with a typically sparse herbaceous layer. The emergent tree layer is typically nonexistent.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Dry Inland, Lower Elevation Inland Santa Monica Mountains, Western Fog Zone, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 114–510 m, mean 297.4 m
Aspect: southeast to northwest
Slope: range 15–42 degrees, mean 27.2 degrees
Topography (micro; macro): variable (all); lower to upper slope
Litter Cover: range 18–18%, mean 18%
Small Rock Cover: range 10–30%, mean 20.8%
Large Rock Cover: range 0–10%, mean 3.2%
Bare Ground: range 15–65%, mean 35.8%
Parent Material: igneous or sedimentary
Soil Texture: medium loam to moderately fine sandy clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Salvia mellifera* Shrubland form an open to intermittent shrub layer (20–45%, mean 34.2%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–15%, mean 4.3%) at 0–1 m tall. Trees are occasionally emergent (0–10% cover, mean 1%) with hardwoods at 0–5 m tall. Total vegetation cover is 31–45%, mean cover is 39.5%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum, Salvia mellifera,* and *Yucca whipplei. Artemisia californica* is usually present, and *Eriogonum fasciculatum* and *Lotus scoparius* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Nassella lepida* and *Trichostema lanatum*. Other herbs occasionally include *Centaurea melitensis, Bromus diandrus, Calystegia macrostegia, Cuscuta californica, Bromus madritensis,* and *Melica imperfecta*.

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 11 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Lepechinia fragrans was found in 1of 11 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Avena barbata, Bromus madritensis, Bromus diandrus, Centaurea melitensis, Avena fatua, Schinus molle, Avena, Hirschfeldia incana, Brassica nigra, Bromus hordeaceus, Rosmarinus officinalis, Sonchus oleraceus

Samples Used in Description: (n = 11)
AA0315cc, AA0762, rap0569, rap0588, rap0708, rap1224, rap1778, rap1824, rap1856, rap2119, rap2833

Comments:
Locally this association is often seral showing the evidence of recent fire such as the presence of *Hazardia squarrosa* and *Lotus scoparius.* However, some stands of this association appear to have persisted for much longer periods since the most recent fire event. In general, most of the local stands seem to have a stronger affinity toward coastal scrub species than toward chaparral as indicated by the average constancy of the most common shrub species. This is a transitional association that would be valuable to monitor over the long term to clarify regional trends in scrub dynamics between chaparral and coastal scrub vegetation formations.

Phases:
None

COMMON NAME Chamise-Black Sage Shrubland Association

SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Adenostoma fasciculatum-Salvia mellifera* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is found in the central coast of California (including Santa Clara County) and in southern California (including inner south coast; western transverse ranges; and Santa Ana, San Jacinto, San Gabriel, and San Bernardino mountains) per Sawyer and Keeler-Wolf (1995).

Nations:
United States

States or Provinces:
CA

Environmental Description:
Stands are found at elevations between 100 and 1,000 m on all aspects. Slopes are gentle to steep with variable topography. Parent material is more often granite and less often sedimentary, metamorphic, gabbro, diorite, or metavolcanic. Soil texture varies from sandy loam to silty clay loam.

Vegetation Description:
Stands of *Adenostoma fasciculatum-Salvia mellifera* Shrubland form an open to continuous shrub layer (10–75%, mean 44.2%) where *Adenostoma fasciculatum* usually codominates with *Salvia mellifera*. The shrub layer is often in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to continuous (0.2–75%, mean 22.7%) at 0–1 m tall with a variety of native and nonnative species (see species table). Total vegetation cover is 38–85%, mean cover is 59.2%.

Comments:
This is a widespread association in the central and southern coastal parts of California. It is one of the classic intermixings of chaparral and coastal sage scrub in the California mediterranean climate.

Adenostoma fasciculatum-Salvia mellifera-Malosma laurina Shrubland Association

Chamise-Black Sage-Laurel Sumac Shrubland Association
***Adenostoma fasciculatum-Salvia mellifera* Shrubland Alliance**
Chamise-Black Sage Shrubland Alliance

Mapping Code: 2035

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 0–648 m. It is codominated by *Adenostoma fasciculatum* and *Salvia mellifera* in the shrub layer with *Malosma laurina* as a subdominant. It has an insignificant herbaceous layer. The emergent tree layer is usually absent but infrequently includes occasional individuals of *Quercus agrifolia* and *Juglans californica*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Simi Hills Inland, Western Fog Zone, Dry Inland, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, and the Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 0–648 m, mean 400 m
Aspect: variable
Slope: range 4–35 degrees, mean 25 degrees
Topography (micro; macro): flat, undulating, or convex; lower slope to ridge
Litter Cover: range 0–45%, mean 19.4%
Small Rock Cover: range 1–60%, mean 27.5%
Large Rock Cover: range 0–15%, mean 3%
Bare Ground: range 0–55%, mean 33.9%
Parent Material: igneous or sedimentary
Soil Texture: medium loam to moderately fine sandy clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Salvia mellifera-Malosma laurina* Shrubland form an open to intermittent shrub layer (18–50%, mean 36.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–17%, mean 1.2%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 28–52%, mean cover is 37.9%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum, Salvia mellifera,* and *Malosma laurina. Yucca whipplei* and *Eriogonum fasciculatum* are usually included in this layer, and *Lotus scoparius* is occasionally present. The tree layer is emergent and open and may rarely include *Quercus agrifolia* and/or *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Centaurea melitensis,* and *Trichostema lanatum*. Other herbs may include *Bromus madritensis* and/or *Galium angustifolium*.

Comments:
This is a very common and widespread association within the Santa Monica Mountains but is not known elsewhere. The presence of *Malosma laurina* within stands of *A. fasciculatum* and *Salvia mellifera* is apparently largely restricted to the coastal strip of southern California. As with the *A. fasciculatum-S. mellifera* association of the same alliance, this association is often indicative of relatively recent fire.

Adenostoma fasciculatum-Salvia mellifera-Rhus ovata Shrubland Association

Chamise-Black Sage-Sugar Bush Shrubland Association
***Adenostoma fasciculatum-Salvia mellifera* Shrubland Alliance**
Chamise-Black Sage Shrubland Alliance

Mapping Code: 2038

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes of variable aspect at low elevations between 17–552 m. It is dominated by *Adenostoma fasciculatum* and *Salvia mellifera* in the shrub layer with *Rhus ovata* as a subdominant. The herbaceous layer is generally poorly developed. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains, Dry Inland and Upper Elevation Santa Monica Mountains, Simi Hills Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 17–552 m, mean 354.5 m
Aspect: variable
Slope: range 15–38 degrees, mean 30.2 degrees
Topography (micro; macro): flat, convex, or undulating; lower slope to ridgetop
Litter Cover: range 15–30%, mean 22.5%
Small Rock Cover: range 5–30%, mean 15%
Large Rock Cover: range 0–2%, mean 0.4%
Bare Ground: range 10–50%, mean 31%
Parent Material: sedimentary, some igneous
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Salvia mellifera-Rhus ovata* Shrubland form an open to intermittent shrub layer (32–60%, mean 42.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–3%, mean 0.6%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.2%) with hardwoods at 0–10m tall. Total vegetation cover is 33–62%, mean cover is 43.3%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum*, *Salvia mellifera,* and *Rhus ovata*. *Eriogonum fasciculatum* and *Malacothamnus fasciculatus* are occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and may include *Centaurea melitensis, Cuscuta californica,* and *Trichostema lanatum*.

Comments:
This association is the most inland of the three locally represented associations of the *Adenostoma fasciculatum-Salvia mellifera* Alliance. *Rhus ovata* is most commonly found in the hotter and more dry continental climates of southern California; in the local area these stands may be found in areas that experience frequent frost in winter. The hybridization between *Rhus ovata* and *Rhus integrifolia* in the study area makes many individual shrubs in the genus *Rhus* difficult to identify. Occasional hybrids were found in these stands, but most *Rhus* appeared to be more characteristic of *R. ovata.*

Phases:
None

Adenostoma sparsifolium Shrubland Alliance

Redshank Shrubland Alliance

Mapping Code: 2050

Local Description

Summary:
This shrubland alliance occurs on somewhat steep southwest- and southeast-facing slopes at low to mid elevations between 356–844 m. It is dominated by *Adenostoma sparsifolium* in the shrub layer. The emergent tree layer includes occasional *Quercus agrifolia*.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 356–844 m, mean 656 m
Aspect: southwest and southeast
Slope: range 15–35 degrees, mean 21.6 degrees
Topography (micro; macro): undulating or concave; lower to upper slope
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: 25%
Bare Ground: no data
Parent Material: igneous
Soil Texture: no data

Vegetation Description:
Stands of this shrubland alliance form an intermittent shrub layer (47–52%, mean 49.3%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is bare (0%). Trees are occasionally emergent (0–0.2% cover, mean 0.1%) with hardwoods at 0–5 m tall. Total vegetation cover is 47–52%, mean cover is 49.3%.

In this association, the shrub layer is characterized by *Adenostoma sparsifolium, Rhus ovata, Ceanothus spinosus,* and *Malosma laurina*. *Heteromeles arbutifolia, Salvia mellifera*, *Ceanothus megacarpus,* and *Adenostoma fasciculatum* are often included in this layer. Occasional, small trees are emergent and may include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Leymus condensatus* and *Bromus* sp.

Herb									
	BROMU	*Bromus*	33	0.1	0.2	0.2			
	LECO12	*Leymus condensatus*	33	0.1	0.2	0.2			

Other Noteworthy Species:
Lepechinia fragrans was found in 1of 3 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
None

Samples Used in Description: (n = 3)
rap0527m, rap2496, rap2928

Comments:
Most stands with significant *A. sparsifolium* in the Santa Monica Mountains are considered part of the *A. sparsifolium-Adenostoma fasciculatum* Alliance. The three relatively pure stands represented in this alliance level description all have relatively high cover of *Ceanothus spinosus* and with further verification may be considered to be an *A. sparsifolium-C. spinosus* Association. Such stands are apparently rare in the study area and are not likely to be found outside of the study area.

Phases:
None

COMMON NAME Redshank Alliance
SYNONYM Ribbonwood or Chamise-Redshank Community
PHYSIOGNOMIC CLASS III. Shrubland

PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.2. Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.2.N. Natural/Seminatural
FORMATION	III.A.2.N.C. Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Adenostoma sparsifolium* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This alliance occurs from California's central coast, south into the cismontane transverse and peninsular ranges, extending into northern Baja California, Mexico.

Nations:
United States, Mexico

States or Provinces:
CA, Baja California Norte

Environmental Description:
The *Adenostoma sparsifolium* Shrubland Alliance grows on dry slopes and flats with deep soils derived from alluvium or bedrock. Stands occur from 300 to 2,000 m in elevation. This alliance is adapted to slightly cooler temperatures and drier conditions than other widespread chaparral vegetation types. Summers are dry and winters are relatively cool and moist. This alliance often occurs in a mosaic with the *Adenostoma fasciculatum* Shrubland Alliance. Keeler-Wolf et al. (1998) show an *Adenostoma sparsiflorum* Alliance and the closely related *Adenostoma fasciculatum-Adenostoma sparsiflorum* Alliance as occurring adjacent to desert vegetation types along much of the northwestern portion of Anza-Borrego Desert State Park.

Vegetation Description:
This shrubland of California and Baja California is dominated by *Adenostoma sparsifolium* that may be the sole shrub in the canopy. Other shrubs may include *Cercocarpus montanus* var. *glaber, Adenostoma fasciculatum, Ceanothus greggii, Rhamnus ilicifolia, Quercus cornelius-mulleri*, and *Garrya veatchii*. The herbaceous layer is sparse.

Comments:
In a study of the range of *Adenostoma sparsifolium,* Marion (1943) found monotypic stands of redshank in just 3% of its distribution; more often it intermixes with chamise.

Keeler-Wolf et al. 1998, Marion 1943, Reid et al. 1999, Sawyer and Keeler-Wolf 1995

Arctostaphylos glandulosa Shrubland Alliance

Eastwood Manzanita Shrubland Alliance

Mapping Code: 2550

Local Description

Summary:
This shrubland alliance occurs on somewhat steep to steep northwest-facing slopes at low to middle to high elevations between 557–878 m. It is dominated by *Arctostaphylos glandulosa* in the shrub layer and has an insignificant herbaceous layer in the mature stands. The emergent tree layer includes *Quercus agrifolia* in about one-third of the stand sampled.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 557–878 m, mean 755 m
Aspect: northwest
Slope: range 20–35 degrees, mean 27.6 degrees
Topography (micro; macro): undulating or concave; middle slope to ridge
Litter Cover: 75%
Small Rock Cover: range 5–13%, mean 9%
Large Rock Cover: range 3–15%, mean 9%
Bare Ground: range 2–10%, mean 6%
Parent Material: igneous or metamorphic
Soil Texture: medium to very fine loamy sand

Vegetation Description:
Stands of this shrubland alliance form an intermittent shrub layer (38–65%, mean 54.3%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is bare (<1%). Occasionally emergent trees are present (0–0.2% cover, mean 0.1%) with hardwoods from 0–10 m tall. Total vegetation cover is 38–65%, mean cover is 54.3%.

In this association, the shrub layer is dominated by *Arctostaphylos glandulosa*. *Heteromeles arbutifolia* and *Adenostoma fasciculatum* are also usually present but at much lower cover values. Other shrubs occasionally present include *Helianthemum scoparium, Ceanothus crassifolius, Lepechinia fragrans, Ceanothus oliganthus, Adenostoma sparsifolium, Quercus berberidifolia,* and *Ceanothus megacarpus. The* tree layer is emergent and open and may include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Marah macrocarpus* and *Zigadenus fremontii*.

Other Noteworthy Species:
Lepechinia fragrans was found in 2 of 3 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Leptodactylon californicum was found in 1of 3 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G5T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
None

Samples Used in Description: (n = 3)
rap0235, rap0790m, rap1533

Comments:
This alliance is only found at the upper elevations of the study area. It is much more widespread in the higher mountains of the transverse and peninsular ranges of southern California.

Phases:
None

COMMON NAME Eastwood Manzanita Alliance
SYNONYM Montane Manzanita Chaparral (Holland 1986)
PHYSIOGNOMIC CLASS III. Shrubland

PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.2. Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.2.N. Natural/Seminatural
FORMATION	III.A.2.N.c. Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Arctostaphylos glandulosa* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This alliance is found along California's outer north coast, outer central coast, and along the montane transverse and peninsular ranges. It may also occur in the northern portion of Baja California, Mexico.

Nations:
United States, Mexico

States or Provinces:
CA, Baja California Norte

Environmental Description:
The *Arctostaphylos glandulosa* Shrubland Alliance of California is found on north-facing slopes, outcrops, and ridges on shallow soils. Occurrences range in elevation from 300 to 2,200 m. This alliance often follows disturbance, growing on sites that have been burned, logged, or otherwise disturbed.

Vegetation Description:
This shrubland is characterized by a continuous canopy of sclerophyllous broad-leaved, evergreen shrubs less than 3 m in height. Emergent conifers may be present. The herbaceous layer is sparse or absent. *Arctostaphylos glandulosa* dominates this alliance. Six subspecies of *Arctostaphylos glandulosa* are recognized by the Jepson Manual (Hickman 1993), any of which may occur in this alliance. Other shrubs present often include *Arctostaphylos glauca, Adenostoma fasciculatum, Ceanothus leucodermis, Yucca whipplei, Baccharis pilularis, Quercus wislizeni, Quercus dumosa, Rhus ovata*, and *Heteromeles arbutifolia*. Emergent *Pinus coulteri* may be present.

Comments:
There are several subspecies of *A. glandulosa.* Most of them are montane and typically occur above 600 m elevation. All are resprouters with lignotubers.

Hickman 1993, Holland 1986, Sawyer and Keeler-Wolf 1995

Arctostaphylos glauca Shrubland Alliance

Big Berry Manzanita Shrubland Alliance

Mapping Code: 2540

Local Description

Summary:
This shrubland alliance occurs on somewhat steep northwest-facing slopes at low elevation (382 m). It is solely dominated by *Arctostaphylos glauca* in the shrub layer. No species were recorded for the herbaceous and tree layers.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: 382 m
Aspect: northwest
Slope: 15 degrees
Topography (micro; macro): flat; mid to upper slopes
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: igneous
Soil Texture: no data

Vegetation Description:
One stand of *Arctostaphylos glauca* Shrubland forms an intermittent shrub layer (55%). Shrubs occur in two different strata with low shrubs at 0.5–1 m tall and tall shrubs at 1–2 m tall. The herbaceous layer and emergent tree layer were not recorded for this stand. Total vegetation cover is 55%.

In this alliance, the shrub layer is intermittent and was solely dominated by *Arctostaphylos glauca*. *Adenostoma fasciculatum* occurred at low cover as did *Malosma laurina*. No species were recorded for the tree layer or herbaceous layer.

Arctostaphylos glauca Alliance

Layer	Code	Species Name	Con	Avg	Min	Max	A	C	N
Shrub									
	ARGL4	*Arctostaphylos glauca*	100	48.0	48.0	48.0	X	X

	MALA6	*Malosma laurina*	100	2.0	2.0	2.0		X	

Other Noteworthy Species:
None

Nonnative Species:
None

Samples Used in Description: (n = 1)
rap0411

Comments:
The one stand was assessed at a distance. Big berry manzanita stands are not common but local in the Simi Hills portion of the study area on northerly slopes.

Phases:
None

COMMON NAME	Big Berry Manzanita Shrubland Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.2. Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.2.N. Natural/Seminatural
FORMATION	III.A.2.N.c. Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Arctostaphylos glauca* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This alliance is known to occur in the central coast (including Santa Clara County south to Santa Barbara County), inner south coast, and montane transverse and peninsular ranges (including from southern San Bernardino Mountains, San Jacinto Mountains, and San Diego County western foothills) to Baja California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
Stands occur on moderate to steep slopes that are typically granitic or metamorphic parent material, though some are found on serpentine. Soils usually have a sandy loam or loam texture, most often shallow to moderately deep.

Vegetation Description:
Arctostaphylos glauca is primarily the dominant shrub in the overstory. *Adenostoma fasciculatum* is often present in relatively low cover. The herbaceous layer may be sparse to well developed including a variety of native species including *Camissonia* spp., *Galium* spp., *Marah macrocarpus, Melica* spp., and *Phacelia* spp.

Comments:
None

Artemisia californica Shrubland Association

California Sagebrush Shrubland Association
***Artemisia californica* Shrubland Alliance**
California Sagebrush Shrubland Alliance

Mapping Code: 8213

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 0–609 m. It is characterized by a dominance of *Artemisia californica* in the shrub layer, and a scattered, mostly nonnative herbaceous layer. The emergent tree layer infrequently includes *Quercus agrifolia, Juglans californica,* and *Schinus molle*.

Distribution:
This association is sampled in the Simi Hills Inland, Immediate Coast, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, Dry Inland Upper Elevation Santa Monica Mountains, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 0–609 m, mean 247.4 m
Aspect: variable
Slope: range 1–45 degrees, mean 21.5 degrees
Topography (micro; macro): convex, undulating, or flat; lower slope to ridgetop
Litter Cover: range 2–80%, mean 33.7%
Small Rock Cover: range 0–55%, mean 16.5%
Large Rock Cover: range 0–20%, mean 1.7%
Bare Ground: range 10–98%, mean 40%
Parent Material: sedimentary or igneous, occasional quaternary alluvium
Soil Texture: medium loam to moderately fine sandy clay loam

Vegetation Description:
Stands of *Artemisia californica* Shrubland form an open to intermittent shrub layer (5–49%, mean 29%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to intermittent (0–51%, mean 7.9%) at 0–2 m tall. Trees are occasionally emergent (0–8% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 14–65%, mean cover is 37.2%.

In this association, the shrub layer is characterized by *Artemisia californica. Malosma laurina* and *Salvia leucophylla* are usually present. *Baccharis pilularis* and *Salvia mellifera* are occasionally included in the shrub layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia, Juglans californica,* or *Schinus molle* at low cover. The herbaceous layer is diverse and sometimes includes *Bromus madritensis, Brassica nigra, Centaurea melitensis, Hirschfeldia incana, Leymus condensatus,* and *Bromus diandrus.*

Comments:
This is an abundant association in the SAMO study area. All stands are strongly dominated by *A. californica*. Many stands have low cover of *Baccharis pilularis,* and a smaller number of stands have *Lotus scoparius.* Both species are generally considered seral in the area, suggesting this association is also reflective of somewhat recent disturbance. This is also underscored by a low cover of several nonnative annual grasses and herbs in many of the plots. The phase with annual grass-herb understory suggests a degraded version or a postfire setting (see below).

Phases:
Artemisia californica-Malosma laurina (California Sagebrush-Laurel Sumac) Phase [3219]
Artemisia californica-Salvia leucophylla (California Sagebrush-Purple Sage) Phase [3211]
Artemisia californica/Annual Grass-Herb (California Sagebrush/Annual Grass-Herb) Phase [8213]

COMMON NAME	California Sagebrush Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic subdesert shrubland
ALLIANCE	*Artemisia californica* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains and San Diego County (Evens and San 2005). It is likely to occur in many other parts of California from the central coast ranges south to at least the Mexican border.

Nations:
United States

States or Provinces:
CA

Environmental Description: (Additional Information from Evens and San [2005])
Elevation: below 700 m
Aspect: mostly southwest, but occasionally northeast and rarely northwest

Slope: gentle to steep, mostly moderate
Topography: undulating, concave, flat, and convex; lower slope to ridgetop
Litter Cover: range 11.7–95%, mean 58.6%
Rock Cover: range 1.2–18%, mean 8.8%
Bare Ground: range 12–65%, mean 38%
Parent Material: often mesozoic granite, occasionally sandstone
Soil Texture: more often medium to very fine sandy loam; occasionally moderately fine sandy clay loam, moderately fine clay loam, medium sand, or fine sandy clay

Vegetation Description:
In the *Artemisia californica* Association, *Artemisia californica* is the sole dominant shrub in the understory, while herbaceous species may be abundant in the understory including *Nassella lepida, Bromus madritensis,* and *Centaurea melitensis.* Shrub species *Malosma laurina* and *Eriogonum fasciculatum* are often present but in relatively low cover.

Comments:
Although not described as an association beyond this study and the study of the San Dieguito River drainage by Evens and San (2005), this is likely to be a common association throughout much of the range of the *Artemisia californica* Alliance. Borchert et al. (2004) describe strongly dominated *A. californica* stands from the Los Padres National Forest of Monterey County south to Ventura County. Gordon and White (1994) describe this alliance in a similar setting to Borchert et al. White and Padley (1997) describe a California sagebrush series (alliance) in Riverside County that has a mean elevation of 1,350 ft.

Borchert et al. 2004, Evens and San 2005, Gordon and White 1994, White and Padley 1997

Artemisia californica/Leymus condensatus Shrubland Association

California Sagebrush/Giant Wild Rye Shrubland Association
***Artemisia californica* Shrubland Alliance**
California Sagebrush Shrubland Alliance

Mapping Code: 3216

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 38–432 m. It is characterized by *Artemisia californica* in the shrub layer and *Leymus condensatus* in the herbaceous layer. The emergent tree layer is usually absent but may include *Quercus agrifolia* and *Juglans californica*.

Distribution:
This association is sampled in the Immediate Coast, Western Fog Zone, Dry Inland, Simi Hills Inland, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 38–432 m, mean 272.5 m
Aspect: variable
Slope: range 2–35 degrees, mean 28.3 degrees
Topography (micro; macro): variable (all); lower to upper slope
Litter Cover: range 30–75%, mean 52.5%
Small Rock Cover: range 3–5%, mean 4.5%
Large Rock Cover: range 0–7%, mean 1.8%
Bare Ground: range 7–60%, mean 26%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Artemisia californica/Leymus condensatus* Shrubland form an open to intermittent shrub layer (14–52%, mean 29.9%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (2–39%, mean 16.2%) at 0.1–2 m tall. Trees are occasionally emergent (0–5% cover, mean 0.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 25–60%, mean cover is 47%.

In this association, the shrub layer is characterized by *Artemisia californica. Salvia leucophylla, Toxicodendron diversilobum,* and *Mimulus aurantiacus* are usually included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and is characterized by *Leymus condensatus.* Other herbs sometimes include *Brassica nigra, Malacothrix saxatilis, Bromus diandrus, Hirschfeldia incana,* and *Melica imperfecta*.

Other Noteworthy Species:
Baccharis plummerae was found in 1 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-1-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Eriogonum crocatum was found in 1of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.1 (CNPS 2005). Federal listing is Species of Concern, and state listing is Rare (SAMO 2004).

Juglans californica was found in 3 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Comments:
This association of the *A. californica* Alliance is characterized by a codominance of California sagebrush and giant wild rye. This condition tends to develop as a result of fire on relatively mesic slopes that may have formerly contained a mixture of *A. californica* with other species prior to the fire. Both *Leymus condensatus* and *Malacothamnus fasciculatus* (found in about 40% of the plots) tend to increase in cover following recent fire. However, the association may be more persistent in areas with seasonal seeps or natural ground disturbance.

Phases:
None

Artemisia californica-Eriogonum cinereum Shrubland Association

California Sagebrush-Ashy Buckwheat Shrubland Association
***Artemisia californica* Shrubland Alliance**
California Sagebrush Shrubland Alliance

Mapping Code: 3214

Local Description

Summary:
This shrubland association occurs on moderately steep to very steep slopes of variable aspect at low elevations between 0–460 m. It is characterized by *Artemisia californica* and *Eriogonum cinereum* in the shrub layer. The herbaceous layer is generally insignificant but does include several native species of grasses. The emergent tree layer is generally absent but may include *Quercus agrifolia* and *Juglans californica*.

Distribution:
This association is sampled in the Western Fog Zone, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Dry Inland Simi Hills, Inland Upper Elevation Santa Monica Mountains, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 0–460, mean 177 m
Aspect: variable but most often southwest or southeast
Slope: range 6–50 degrees, mean 30.7 degrees
Topography (micro; macro): flat or convex; lower slope to ridgetop
Litter Cover: range 15–45%, mean 21.8%
Small Rock Cover: range 0–60%, mean 21%
Large Rock Cover: range 0–15%, mean 2.8%
Bare Ground: range 0–80%, mean 35%
Parent Material: sedimentary or igneous
Soil Texture: medium loam to moderately fine sandy clay loam

Vegetation Description:
Stands of *Artemisia californica-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (12–48%, mean 31.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–30%, mean 6%) at 0–1 m tall. Trees are occasionally emergent (0–10% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 12–51%, mean cover is 36.9%.

In this association, the shrub layer is characterized by *Artemisia californica* and *Eriogonum cinereum. Malosma laurina, Yucca whipplei,* and *Salvia mellifera* are usually included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Leymus condensatus, Melica imperfecta,* and *Bromus madritensis.*

Comments:
This is a very common and largely endemic association to the more coastal portions of the Santa Monica Mountains. It occupies relatively steep slopes usually on southerly facing exposures. Two minor phases of this association have been identified. The one with *Melica imperfecta* may indicate slightly more mesic conditions.

Phases:
Artemisia californica-Eriogonum cinereum (California Sagebrush-Ashy Buckwheat-Black Sage) Phase [3214]
Artemisia californica-Eriogonum cinereum-Mimulus aurantiacus/Melica imperfecta (California Sagebrush-Ashy Buckwheat-Bush Monkey Flower) Phase [3218]

Artemisia californica-Mimulus aurantiacus Shrubland Association

California Sagebrush-Bush Monkey Flower Shrubland Association
***Artemisia californica* Shrubland Alliance**
California Sagebrush Shrubland Alliance

Mapping Code: 8214

Local Description

Summary:
This shrubland association occurs on moderately steep to steep southwest- to northeast-facing slopes at low elevations between 160–467 m. It is characterized by a codominance of *Artemisia californica* and *Mimulus aurantiacus* in the shrub layer. Although no individual species are strongly characteristic in the herbaceous layer, the native perennial grasses *Melica imperfecta* and *Leymus condensatus* occur in about half of the samples. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Western Fog Zone, Eastern Urban, Upper Elevation Santa Monica Mountains, Simi Hills Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 160–467 m, mean 327.8 m
Aspect: southwest to northeast
Slope: range 10–35 degrees, mean 27.3 degrees
Topography (micro; macro): flat or convex; middle to upper slope
Litter Cover: range 45–60%, mean 50%
Small Rock Cover: range 0–20%, mean 9.3%
Large Rock Cover: range 0–10%, mean 4%
Bare Ground: range 20–55%, mean 36.2%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Artemisia californica-Mimulus aurantiacus* Shrubland form an open to intermittent shrub layer (24–51%, mean 37%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–12%, mean 5.5%) at 01–1 m tall. Trees are occasionally emergent (0–7% cover, mean 0.9%) with conifers at 0–15 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 35–52%, mean cover is 43.5%.

In this association, the shrub layer is characterized by *Artemisia californica* and *Mimulus aurantiacus. Malosma laurina* is usually present. *Ribes malvaceum* and *Ceanothus megacarpus* are occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Melica imperfecta* and *Leymus condensatus.*

AA0885, rap0612, rap0951, rap1153, rap1375, rap1733, rap1768, rap1971, rap2487, rap2814

Comments:
In general, this association occurs in relatively steep coastal settings. It tends to occupy more mesic settings than the associations of the *Artemisia californica-Eriogonum fasciculatum* alliance.

Phases:
None

COMMON NAME	California Sagebrush-Bush Monkey Flower Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic subdesert shrubland
ALLIANCE	*Artemisia californica* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region, although this association is to be expected elsewhere in coastal central and southern California. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Traditionally in the shrublands with a codominance of *Artemisia californica* and other species (*Eriogonum fasciculatum, Salvia leucophylla*, etc.), California ecologists have erected mixed alliance names bases on the codominant species (e.g., Gordon and White 1994). This is the first case when a codominant *A. californica- Mimulus aurantiacus* Association has been described, so we have decided not to describe it as a new alliance but simply as an association within the broader view of the *Artemisia californica* Alliance. The proliferation of mixed alliances based on codominance is a philosophical dilemma that will continue to plague ecologists in California for some time to come.

Artemisia californica-Eriogonum fasciculatum/Annual Grass-Herb Shrubland Association

California Sagebrush-California Buckwheat/Annual Grass-Herb Shrubland Association
***Artemisia californica-Eriogonum fasciculatum* Shrubland Alliance**
California Sagebrush-California Buckwheat Shrubland Alliance

Mapping Code: 3371

Local Description

Summary:
This shrubland association occurs on gentle to steep southwest- and southeast-facing slopes at low elevations between 99–442 m. It is characterized by a codominance of *Artemisia californica* and *Eriogonum fasciculatum* in the shrub layer. There are a variety of native and nonnative species in the herbaceous layer, none particularly characteristic. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Western Fog Zone, Dry Inland, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 99–442 m, mean 277.2 m
Aspect: southwest and southeast
Slope: range 2–35 degrees, mean 22 degrees
Topography (micro; macro): flat or undulating; lower to upper slope
Litter Cover: range 25–30%, mean 27.5%
Small Rock Cover: range 2–27%, mean 14.8%
Large Rock Cover: range 2–50%, mean 16.8%
Bare Ground: range 3–45%, mean 22.5%
Parent Material: igneous or quaternary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Artemisia californica-Eriogonum fasciculatum*/Annual Grass-Herb Shrubland form an open to intermittent shrub layer (10–25%, mean 16.8%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (7–24%, mean 16.7%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.3%) with hardwoods at 0–10 m tall. Total vegetation cover is 26–42%, mean cover is 33.8%.

In this association, the shrub layer is characterized by *Artemisia californica* and *Eriogonum fasciculatum. Malosma laurina* is usually present. *Lotus scoparius* and *Salvia leucophylla* are sometimes included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and often includes *Centaurea melitensis,* while *Hemizonia fasciculata, Bromus diandrus,* and *Hirschfeldia incana* are sometimes present.

Other Noteworthy Species:
Dudleya blochmaniae was found in 1 of 9 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-3-2. Global rank is G2T2, and state rank is S2.1 (CNPS 2005). Federal listing is Species of Concern, and state listing is none (SAMO 2004).

Eriogonum crocatum was found in 1of 9 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.1 (CNPS 2005). Federal listing is Species of Concern, and state listing is Rare (SAMO 2004).

Nonnative Species:
Avena, Centaurea melitensis, Bromus diandrus, Hirschfeldia incana, Avena fatua, Bromus madritensis, Cortaderia, Brassica nigra, Piptatherum miliaceum, Carduus pycnocephalus, Foeniculum vulgare, Lactuca serriola, Lamarckia aurea

Samples Used in Description: (n = 9)
AA0014cc, AA0872, rap1957, rap1959, rap2115, rap2221, rap2258, rap2361, rap2395

Comments:
This association is scattered in stands from the immediate coast into the warmer inland areas of the study area. It often contains short-lived seral species such as *Lotus scoparius, Brickellia californica,* and *Malacothamnus fasciculatus* and tends to be a relatively open scrub of xeric exposures. Its seral relationship to certain chaparrals and coastal scrubs is suggested by the presence of *Salvia leucophylla, Encelia californica,* and *Ceanothus megacarpus* in some of the stands. The open nature of many of the stands is suggested by the relatively high constancy of shade-intolerant herbs such as *Hemizonia fasciculata and Avena* sp. This vegetation type appears to sometimes be related to anthropomorphic disturbance.

Phases:
None

COMMON NAME	California Sagebrush-California Buckwheat/Annual Grass-Herb Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland

ALLIANCE	*Artemisia californica-Eriogonum fasciculatum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is sampled in the California south coast (including Ventura to western Riverside and San Diego counties) and peninsular ranges (western Riverside County: Santa Ana Mountains, Perris Valley and Hills, and Fontana Plain and San Diego County: hills north of Ramona).

Nations:
United States

States or Provinces:
CA

Environmental Description:
The following information is derived from Evens and San (2005) and Klein and Evens (2005). Elevation ranges from 95 to 1,095 m with aspects variable (north to south). Slopes are gentle to steep, and topography is variable. Parent material is more often sedimentary or granite, less often gabbro, diorite, metavolcanic, or mixed granitic and metamorphic. Soil texture is more often sandy loam but varies from sand to clay loam.

Vegetation Description:
Stands of *Artemisia californica-Eriogonum fasciculatum* Shrubland form an open to continuous shrub layer (10–78%), where *Artemisia californica* usually codominates with *Eriogonum fasciculatum*. Shrubs sometimes occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0.2–60%,) at 0–1 m tall and includes a variety of native and nonnative species. Emergent trees occur infrequently (0.2–8% cover) at 5–15 m tall. Total vegetation cover is 26–88%. Occasional subdominant shrubs include *Salvia apiana*, *Lotus scoparius*, *Tetradymia comosa*, and *Lessingia filaginifolia*. The most common annuals in the herb understory include native *Amsinckia menziesii* and nonnatives *Bromus madritensis*, *Bromus diandrus*, *Bromus hordeaceus*, and *Avena fatua*.

Comments:
This is a widespread association in the central and south coastal areas of California. Similar stands have been seen as far north as San Benito County (Keeler-Wolf 2005 personal observation).

Artemisia californica-Eriogonum fasciculatum-Salvia leucophylla Shrubland Association

California Sagebrush-California Buckwheat-Purple Sage Shrubland Association
***Artemisia californica-Eriogonum fasciculatum* Shrubland Alliance**
California Sagebrush-California Buckwheat Shrubland Alliance

Mapping Code: 3372

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southeast- and southwest-facing slopes at low elevations between 231–527 m. It is characterized by the codominance of *Artemisia californica, Eriogonum fasciculatum*, and *Salvia leucophylla* in the shrub layer. The herbaceous layer is not well developed. The emergent tree layer is generally absent but can include *Quercus agrifolia*.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 231–527 m, mean 366 m
Aspect: southeast and southwest
Slope: range 17–35 degrees, mean 30.8 degrees
Topography (micro; macro): undulating, convex, or flat; lower slope to ridgetop
Litter Cover: range 8–30%, mean 19.5%
Small Rock Cover: range 18–35%, mean 25.8%
Large Rock Cover: range 2–15%, mean 6.3%
Bare Ground: range 25–50%, mean 40%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Artemisia californica-Eriogonum fasciculatum-Salvia leucophylla* Shrubland form an open to intermittent shrub layer (18–41%, mean 32.6%). Shrubs occur in two different strata with low shrubs at 0-1 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (1–13%, mean 4.1%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.3%) with hardwoods at 0–10 m tall. Total vegetation cover is 23–45%, mean cover is 37.1%.

In this association, the shrub layer is characterized by *Artemisia californica, Eriogonum fasciculatum, Salvia leucophylla,* and *Yucca whipplei. Malosma laurina* is often present, and *Salvia apiana* is occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and is characterized by *Centaurea melitensis*, while *Brassica nigra* is often included.

AA0189cc, AA0267cc, AA0536, rap2087, rap2244, rap2260, rap2603, rap2823

Comments:
This association differs from the *Artemisia californica-Eriogonum fasciculatum* Association by having a constant codominance of *Salvia leucophylla* along with the other two major shrubs. It is a relatively uncommon association in the study area and is usually found in the inland portions of the area on very dry, warm, steep south-facing slopes. It is likely to be endemic to the general area of the Ventura region of the coastal sage scrub zone (*sensu* Westman 1981)

Phases:
None

Artemisia californica-Eriogonum fasciculatum-Salvia mellifera Shrubland Association

California Sagebrush-California Buckwheat-Black Sage Shrubland Association
***Artemisia californica-Eriogonum fasciculatum* Shrubland Alliance**
California Sagebrush-California Buckwheat Shrubland Alliance

Mapping Code: 3373

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 0–588 m. It is characterized by a codominance of *Artemisia californica, Eriogonum fasciculatum*, and *Salvia mellifera* in the shrub layer. There is an insignificant herbaceous layer. The emergent tree layer is generally absent but may include *Quercus agrifolia*.

Distribution:
This association is sampled in the Eastern Urban, Upper Elevation Santa Monica Mountains, Western Fog Zone, Dry Inland, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 0–588 m, mean 326.7 m
Aspect: variable
Slope: range 0–35 degrees, mean 23.7 degrees
Topography (micro; macro): flat, undulating, or convex; lower slope to ridge
Litter Cover: range 15–35%, mean 21.9%
Small Rock Cover: range 8–45%, mean 18.7%
Large Rock Cover: range 0–15%, mean 5.5%
Bare Ground: range 25–65%, mean 46.4%
Parent Material: igneous or sedimentary
Soil Texture: medium to moderately fine sandy clay loam

Vegetation Description:
Stands of *Artemisia californica-Eriogonum fasciculatum-Salvia mellifera* Shrubland form an open to intermittent shrub layer (20–39%, mean 30.8%). Shrubs occur in two different strata, with low shrubs at 0–2 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–8%, mean 2.7%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 20–42%, mean cover is 33.7%.

In this association, the shrub layer is characterized by *Artemisia californica, Eriogonum fasciculatum,* and *Salvia mellifera. Malosma laurina* and *Encelia californica* are usually included in this layer. The tree layer is emergent and open and sometimes includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and is characterized by *Centaurea melitensis.* Other herbs sometimes include nonnative annual *Bromus* species.

Comments:
This association is found in the hotter and drier exposures of the study area but generally within the zone of morning summer fog. It is not so strongly restricted to south-facing slopes as the *A. californica-E. fasciculatum-S. leucophylla* Association. It probably ranges more widely than that association as well. It would be expected to occur in other parts of the central and south coastal areas of California.

Atriplex lentiformis Shrubland Alliance

Quail Bush Shrubland Alliance

Mapping Code: 2330

Local Description

Summary:
This shrubland alliance occurs on gentle to steep southeast- and southwest-facing slopes at low elevations between 0–171 m. It is dominated by *Atriplex lentiformis* in the shrub layer and by several nonnative herbs and forbs in the herbaceous layer.

Distribution:
This alliance is sampled in the Immediate Coast and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–171 m, mean 20.6 m
Aspect: southeast and southwest
Slope: range 0–35 degrees, mean 11.6 degrees
Topography (micro; macro): flat to undulating; lower and bottom slope
Litter Cover: range 45–95%, mean 70%
Small Rock Cover: range 0–25%, mean 10.2%
Large Rock Cover: range 0–2%, mean 0.2%
Bare Ground: range 0–80%, mean 41.2%
Parent Material: sedimentary and quaternary
Soil Texture: fine clay

Vegetation Description:
Stands of this shrubland alliance form an open to intermittent shrub layer (8–55%, mean 25.8%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0–34%, mean 13.3%) at 0–1 m tall. Trees are occasionally emergent (0–6% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 15–64%, mean cover is 39.4%.

In this association, the shrub layer is characterized by *Atriplex lentiformis. Baccharis pilularis* and *Myoporum laetum* are often present, while *Rhus integrifolia* and *Artemisia californica* are occasionally included in this layer. The tree layer is rare, emergen, and open. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Bromus madritensis, Carpobrotus edulis,* and *Malacothrix saxatilis.*

Comments:
The local stands of this alliance may have been largely the result of plantings by CalTrans and other agencies along the Highway 1 corridor. Several of these stands appear self-perpetuating now. The decision was made to make no further attempt to differentiate these stands into local associations as a result of their possible introduced nature and the general heterogeneity of the species composition. Note the extensive list of nonnative species associated with these stands, perhaps another indication of their nonnatural origins.

Phases:
None

COMMON NAME	Quail Bush Alliance
SYNONYM	*Atriplex (lentiformis, polycarpa)* Shrubland Alliance (NatureServe 2005), Mixed Saltbush Series (Sawyer and Keeler-Wolf 1995)
FORMATION CLASS	III. Shrubland
FORMATION SUBCLASS	III.A. Evergreen shrubland
FORMATION GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
FORMATION SUBGROUP	III.A.5.N. Natural/Seminatural extremely xeromorphic evergreen shrubland
FORMATION NAME	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic subdesert shrubland
ALLIANCE	*Atriplex lentiformis* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This alliance is also known from the western edge of the Sonoran Desert region in Anza-Borrego Desert State Park (Keeler-Wolf et al. 1998). Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This alliance has been recently segregated from the previously defined *Atriplex lentiformis-A. polycarpa* Alliance (Sawyer and Keeler-Wolf 1995). Based on recent plot data collected over the past 10 years, it is now apparent that both of these species tend to segregate and form their own alliances with frequently different environmental and species characteristics.

Baccharis pilularis/Annual Grass-Herb Shrubland Association

Coyote Brush/Annual Grass-Herb Shrubland Association
***Baccharis pilularis* Shrubland Alliance**
Coyote Brush Shrubland Alliance

Mapping Code: 2311

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes with flat to variable aspect at low elevations between 1–568 m. It is characterized by the dominance of *Baccharis pilularis* in the shrub layer and a variety of nonnative largely annual grasses and herbs in the herbaceous layer. The emergent tree layer includes occasional ruderal trees such as *Schinus molle, Eucalyptus* spp., and *Phoenix canariensis* as well as the native *Quercus agrifolia*.

Distribution:
This association is sampled in the Western Fog Zone, Eastern Urban, Dry Inland, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Upper Elevation Santa Monica Mountains of the study area.

Environmental Description:
Elevation: range 1–568 m, mean 179 m
Aspect: commonly none/flat, sometimes variable
Slope: range 0–35 degrees, mean 6.7 degrees
Topography (micro; macro): flat; bottom to mid slope
Litter Cover: range 45–60%, mean 51.3%
Small Rock Cover: range 0–10%, mean 3.6%
Large Rock Cover: range 0–2%, mean 0.3%
Bare Ground: range 5–55%, mean 25.1%
Parent Material: primarily quaternary, some sedimentary
Soil Texture: moderately fine clay loam to fine clay

Vegetation Description:
Stands of *Baccharis pilularis*/Annual Grass-Herb Shrubland form an open to intermittent shrub layer (6–55%, mean 27.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to continuous (1–71%, mean 17%) at 0–2 m tall. Trees are occasionally emergent (0–3% cover, mean 0.9%) with hardwoods at 0–15 m tall. Total vegetation cover is 9–80%, mean cover is 44.9%.

In this association, the shrub layer is characterized by an abundance of *Baccharis pilularis. Artemisia californica, Sambucus Mexicana,* and *Toxicodendron diversilobum* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia, Schinus molle, Eucalyptus, Juglans californica,* and *Phoenix canariensis* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra* and *Centaurea melitensis.* Other herbs present may include *Bromus diandrus, Phalaris aquatica, Foeniculum vulgare,* and *Erodium cicutarium*.

Comments:
This association is indicative of a disturbed seral stage that, in these mountains, typically comes following the reversion of cleared pastureland or nonnative grassland back to shrubland. *B. pilularis* behaves similarly in these mountains as it does in other areas of northern California (e.g., Bartolome 1989) where it often forms the first wave of woody species to recolonize cleared land. This association has been defined from northern coastal California (Keeler-Wolf et al. 2003), and it is likely to be widespread throughout the coast ranges from northern to southern California. The relatively xeric climate of the local study area compared to areas in northern California where this association has been reported is reflected in a low slope position and locally mesic setting of most of the stands. Stands in the northern part of the state may occur in many topographic settings.

Phases:
None

Baccharis pilularis-Artemisia californica Shrubland Association

Coyote Brush-California Sagebrush Shrubland Association
***Baccharis pilularis* Shrubland Alliance**
Coyote Brush Shrubland Alliance

Mapping Code: 2313

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of flat to variable aspect at low elevations between 2–547 m. It is characterized by a dominance of *Baccharis pilularis* and subdominance of *Artemisia californica* in the shrub layer. The herbaceous layer is more variable than the *B. pilularis*/Annual Grass-Herb Association and tends to have more cover by tall exotic herbs such as *Brassica nigra* and *Foeniculum vulgare.* The emergent tree layer is generally absent but can include exotic ruderals such as *Schinus molle* and *Eucalyptus* spp. as well as the native *Quercus lobata* and *Q. agrifolia*.

Distribution:
This association is sampled in the Western Fog Zone, Dry Inland, Immediate Coast, Simi Hills Inland, Eastern Urban, Lower Elevation Inland Santa Monica Mountains, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 2–547 m, mean 202.2 m
Aspect: flat to variable
Slope: range 0–35 degrees, mean 9.9 degrees
Topography (micro; macro): flat, undulating, or concave; bottom to middle slope
Litter Cover: range 5–85%, mean 46.7%
Small Rock Cover: range 0–70%, mean 12.7%
Large Rock Cover: range 0–15%, mean 1.4%
Bare Ground: range 0–74%, mean 30.4%
Parent Material: quaternary, igneous, or sedimentary
Soil Texture: moderately fine silty or sandy clay loam

Vegetation Description:
Stands of *Baccharis pilularis-Artemisia californica* Shrubland form an open to intermittent shrub layer (8–51%, mean 32.6%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0–45%, mean 8.6%) at 0–2 m tall. Trees are occasionally emergent (0–11% cover, mean 1.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 28–55%, mean cover is 41.9%.

In this association, the shrub layer is characterized by *Baccharis pilularis* and *Artemisia californica. Salvia leucophylla* is often present, while *Malosma laurina* is occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia, Eucalyptus, Schinus molle,* and *Quercus lobata* at low cover. The herbaceous layer is diverse and often includes *Brassica nigra*. *Leymus condensatus, Bromus madritensis, Foeniculum vulgare,* and *Centaurea melitensis* are occasionally present in this layer.

Comments:
This is the most common expression of the *Baccharis pilularis* Alliance locally. As with the *B. pilularis*/Annual Grass-Herb Association, this association is also indicative of seral conditions and is often found in relatively mesic low-lying settings. The large number of nonnative species is also indicative of the disturbed/seral nature of this association. In the La Jolla Valley area of the park, there are stands that appear to be colonizing annual grassland areas, especially in regions of flood disturbance or erosion. In many cases, die-off of the *Baccharis* was noted. Three phases are identified in this type exhibiting augmentation of stands with higher cover and frequency of *Malosma laurina* or *Salvia leucophylla*.

Phases:
Baccharis pilularis-Malosma laurina-Artemisia californica (Coyote Brush-Laurel Sumac-California Sagebrush) Phase [2314]
Baccharis pilularis-Artemisia californica (Coyote Brush-California Sagebrush) Phase [2313]
Baccharis pilularis-Artemisia californica-Salvia leucophylla (Coyote Brush-California Sagebrush-Purple Sage) Phase [2315]

COMMON NAME	Coyote Brush-California Sagebrush Shrubland Association

PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen Shrubland
PHYSIOGNOMIC GROUP	Microphyllous evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Lowland microphyllous evergreen shrubland
ALLIANCE	*Baccharis pilularis* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This association is well known from the Santa Monica Mountains. Similar associations with *Baccharis pilularis* and *Artemisia californica* as main components have been noted as far south as San Diego County (Heady et al. 1977, Kirkpatrick and Hutchinson 1977, Evens and San 2005) and as far north as the San Francisco Bay region (Keeler-Wolf et al. 2003, Evens and San 2004). Borchert et al. 2004 describes a series of 11 stands they call the *B. pilularis-A. californica* Alliance from the coastal portions of the Los Padres National Forest in Monterey County in which the two species codominate. In the Santa Monica Mountains, *B. pilularis* usually dominates, so the association is placed in the *B. pilularis* Alliance. In a few samples in the SAMO study area, *B. pilularis* codominates with *A. californica*; however, not enough samples are present to warrant an alliance designation.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Although similar associations have been described elsewhere, there are minor differences in some of these from the presently described association. There is some debate about whether to to place the associations into the *Baccharis pilularis* Alliance or maintain the mixed *Baccharis pilularis-Artemisia californica* Alliance to contain a range of associations characterized by the presence or codominance of these two species of shrubs. Currently Borchert et al. 2004 recognizes a mixed alliance. However, the samples of this association from Santa Monica Mountains are placed in the *Baccharis pilularis* Alliance since *B. pilularis* is generally dominant while *A. californica* is subdominant.

Borchert et al. 2004, Evens and San 2004, Evens and San 2005, Heady et al. 1977, Keeler-Wolf et al. 2003, Kirkpatrick and Hutchinson 1977

Baccharis salicifolia Riparian Shrubland Association

Mule Fat Riparian Shrubland Association
***Baccharis salicifolia* Shrubland Alliance**
Mule Fat Shrubland Alliance

Mapping Code: 2212

Local Description

Summary:
This shrubland association occurs on gentle to somewhat steep slopes of flat aspect at low elevations between 2–501 m. It is characterized by *Baccharis salicifolia* in the shrub layer and a variety of native and nonnative mesophytic species in the herbaceous layer, perhaps the most characteristic of which is *Artemisia douglasiana*. The emergent tree layer includes riparian species such as *Platanus racemosa*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, Western Fog Zone, Simi Hills Inland, Lower Elevation Inland Santa Monica Mountains, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 2–501 m, mean 200.9 m
Aspect: flat
Slope: range 0–15 degrees, mean 2.8 degrees
Topography (micro; macro): flat or concave; slope bottom
Litter Cover: range 2–80%, mean 41.9%
Small Rock Cover: range 2–70%, mean 21.7%
Large Rock Cover: range 0–75%, mean 10.7%
Bare Ground: range 2–70%, mean 22.9%
Parent Material: quaternary or sedimentary
Soil Texture: coarse to medium loamy sand

Vegetation Description:
Stands of *Baccharis salicifolia*-Riparian Shrubland form an open to intermittent shrub layer (4–48%, mean 27.3%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–28%, mean 8.4%) at 0–2 m tall. Trees are occasionally emergent (0–15% cover, mean 3.1%) with hardwoods at 0–15 m tall. Total vegetation cover is 10–65%, mean cover is 38.5%.

In this association, the shrub layer is characterized by *Baccharis salicifolia. Baccharis pilularis*, *Salix lasiolepis, Nicotiana glauca, Artemisia californica,* and *Malosma laurina* are occasionally included in this layer. The tree layer is emergent and open and may include *Platanus racemosa, Salix laevigata, or Quercus agrifolia* at low cover. The herbaceous layer is diverse and often includes *Artemisia douglasiana,* while *Piptatherum miliaceum* and *Brassica nigra* are sometimes present.

Comments:
This is a common riparian scrub association in the study area, reflecting either intermittent flooding or regular disturbance (by scouring) conditions. It is very similar, if not identical, to many other stands dominated by *Baccharis salicifolia* in the south coastal area of California. As with

many riparian vegetation types, these stands are inherently variable and, hence, this treatment is relatively broad.

ALLIANCE	*Baccharis salicifolia* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. In the broad sense, these types of *B. salicifolia* stands range widely from northern Sacramento Valley and south into Baja California, Mexico.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
A similar *Baccharis salicifolia-Sambucus mexicana* Association has been described from western Riverside County (Klein and Evens 2005). Very similar stands occur at least as far north as Shasta County in the Sacramento Valley of California (Keeler-Wolf personal observation 2004). Because of the inherent variability of these riparian scrublands, it remains to be seen if these associations should stay separate.

Klein and Evens 2005

Ceanothus crassifolius Shrubland Association

Hoary Leaf Ceanothus Shrubland Association
***Ceanothus crassifolius* Shrubland Alliance**
Hoary leaf Ceanothus Shrubland Alliance

Mapping Code: 2063

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes at low elevations between 312 and 640 m. It is solely dominated by *Ceanothus crassifolius* in the shrub layer. Trees and herbs are relatively low in cover and constancy.

Distribution:
This association is sampled in the Simi Hills Inland, Upper Elevation Santa Monica Mountains, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 312–640 m, mean 491.1 m
Aspect: variable, but more often northeast
Slope: range 23–35 degrees, mean 33.7 degrees
Topography (micro; macro): variable but more often undulating; lower to middle slopes
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: no data
Soil Texture: no data

Vegetation Description:
Stands of *Ceanothus crassifolius* Shrubland form an intermittent shrub layer (45–60%, mean 53.7%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is sparse (0–3%, mean 0.6%) at 0–1 m tall. Trees rarely occur as emergent (0–0% cover, mean 0%) with hardwoods at 0–5 m tall. Total vegetation cover is 45–60%, mean cover is 54.3%.

In this association, the shrub layer is solely dominated by *Ceanothus crassifolius. Heteromeles arbutifolia* and *Malosma laurina* are frequently included in this layer at relatively low cover. The tree and herbaceous layers are sparse in cover and low in constancy, though they may include *Platanus racemosa, Quercus agrifolia, Marah macrocarpus,* and *Leymus condensatus.*

AA0034cc, AA0291cc, AA0336, AA0651, AA1210, rap1677m, rap2041, rap2331, rap2824

Comments:
These *Ceanothus crassifolius* Association stands typically occur in relatively inland, continental settings locally and are not found close to the coast within the summer fog zone. Most local stands with *Ceanothus crassifolius* have been placed within the mixed *Adenostoma fasciculatum-Ceanothus crassifolius* Alliance.

Phases:
None

COMMON NAME	Hoary Leaf Ceanothus Shrubland Association

ALLIANCE	*Ceanothus crassifolius* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. It is likely to occur somewhat further north and south in south coastal California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This additional information from Borchert et al. 2004 probably largely applies to the *C. crassifolius* Association within the Santa Ynez Mountains of Santa Barbara County. The hoary leaf ceanothus alliance occupies the middle and upper slopes of east- and souht-facing aspects between elevations of 2,000 and 3,600 feet.

Vegetation Description:
Based on 16 plots sampled in the Santa Ynez Mountains of Santa Barbara County, Borchert et al. 2004 add this information to the local description above: Hoary leaf ceanothus has an average cover of 70%. Chamise and sugar bush have relatively high constancies (88% and 71% respectively) but low (< 10%) averge covers.

Comments:
See local description.

References:
Borchert et al. 2004

Ceanothus crassifolius-Malosma laurina Shrubland Association

Hoary Leaf Ceanothus-Laurel Sumac Shrubland Association
***Ceanothus crassifolius* Shrubland Alliance**
Hoary Leaf Ceanothus Shrubland Alliance

Mapping Code: 2065

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes of variable aspect at low elevations between 337–675 m. It is characterized by a dominance of *Ceanothus crassifolius* and subdominance of *Malosma laurina* in the shrub layer and an insignificant herbaceous layer. The emergent tree layer includes occasional *Quercus agrifolia*.

Distribution:
This association is sampled in the Simi Hills Inland, Upper Elevation Santa Monica Mountains, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 337–675 m, mean 475.5 m
Aspect: variable
Slope: range 15–35 degrees, mean 28.5 degrees
Topography (micro; macro): flat or undulating; lower to upper slope
Litter Cover: range 8–8%, mean 8%
Small Rock Cover: range 6–20%, mean 13.3%
Large Rock Cover: range 0–10%, mean 5%
Bare Ground: range 10–61%, mean 33.7%
Parent Material: sedimentary
Soil Texture: medium loam

Vegetation Description:
Stands of *Ceanothus crassifolius-Malosma laurina* Shrubland form an open to intermittent shrub layer (31–60%, mean 49.1%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–10%, mean 2.1%) at 0–1 m tall. Trees are infrequently present. Total vegetation cover is 41–60%, mean cover is 51.1%.

In this association, the shrub layer is characterized by *Malosma laurina* and *Ceanothus crassifolius. Rhus ovata, Heteromeles arbutifolia, Adenostoma fasciculatum, Salvia mellifera,* and *Eriogonum fasciculatum* are usually included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia* at low cover. The herbaceous layer is simple and may include *Marah macrocarpus, Phacelia parryi, Chaenactis artemisiifolia,* and *Gnaphalium bicolor.*

CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains and western Riverside County regions. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
A larger number of samples (n = 23) of this association were taken from a recent study of the vegetation of western Riverside County (Klein and Evens 2005). Below is a summary of the environmental setting:
Elevation: low, range 228–889 m, mean 524 m
Aspect: all aspects (except flat)
Slope: moderate to steep, range 12–45 degrees, mean 29.1 degrees
Topography: undulating or convex, lower to top slopes
Litter Cover: range 4–90%, mean 52.4%
Rock Cover: range 1–45%, mean 19.6%
Bare ground: range 2–85%, mean 24.3%
Parent Material: often metavolcanic, less often gabbro and diorite, sedimentary, mesozoic granite
Soil Texture: often medium to very fine sandy loam, but varies from coarse loamy sand to moderately fine silty clay loam

Vegetation Description:
To supplement the above local description, the following information from Klein and Evens 2005 may be added: *Ceanothus crassifolius* dominates in the shrub layer while *Malosma laurina* and *Adenostoma fasciculatum* are subdominant to codominant. *Salvia mellifera* and *Heteromeles arbutifolia* are characteristically present at low cover.

Comments:
This association is likely to be found in other parts of south coastal California at least as far south as the Mexican border.

Klein and Evens 2005

Ceanothus cuneatus-Quercus berberidifolia Shrubland Association

Wedge Leaf Ceanothus-Scrub Oak Shrubland Association
***Ceanothus cuneatus* Shrubland Alliance**
Wedge Leaf Ceanothus Shrubland Alliance

Mapping Code: 2521

Local Description

Summary:
This shrubland association occurs on somewhat steep northeast- and southeast-facing slopes at low elevations between 226–408 m. It is characterized by *Ceanothus cuneatus* as the dominant shrub with about half as much cover provided by *Quercus berberidifolia*. As with many chaparral association, the herbaceous layer is relatively insignificant in mature stands. The emergent tree layer includes *Quercus agrifolia* and occasional small trees of *Fraxinus dipetala*.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 226–408 m, mean 267 m
Aspect: northeast and southeast
Slope: range 15–35 degrees, mean 24.7 degrees
Topography (micro; macro): flat, undulating, or convex; lower slope to ridgetop
Litter Cover: range 50–50%, mean 50%
Small Rock Cover: range 1–15%, mean 8%
Large Rock Cover: range 0–3%, mean 1.5%
Bare Ground: range 2–25%, mean 13.5%
Parent Material: igneous
Soil Texture: fine clay

Vegetation Description:
Stands of *Ceanothus cuneatus-Quercus berberidifolia* Shrubland form an open to intermittent shrub layer (26–60%, mean 48.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–18%, mean 3.2%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 41–61%, mean cover is 52%.

In this association, the shrub layer is characterized by *Ceanothus cuneatus, Quercus berberidifolia, Adenostoma fasciculatum, Cercocarpus betuloides,* and *Rhus ovata. Heteromeles arbutifolia* is often included in this layer, while *Sambucus mexicana* is occasionally present. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Marah macrocarpus, Hemizonia fasciculate, Hirschfeldia incana, Centaurea melitensis,* and *Avena fatua*.

Comments:
A similarly named and potentially synonymous association, *Quercus berberidifolia-Ceanothus cuneatus* tentatively placed in the *Quercus berberidifolia* Alliance (Gordon and White 1994), has been described from the western transverse ranges of southern California. Gordon and White's brief provisional description suggests that both *Q. berberidifolia* and *C. cuneatus* codominate the stands. In the local Santa Monica Mountains setting, *Ceanothus cuneatus* typically dominates, but occasionally *Q. berberidifolia* codominates. It may be that the Santa Monica Mountains represent the lower elevation coastward expression of this broader association that may also occur in the San Gabriel and other mountains of the transverse ranges at somewhat higher elevations.

Phases:
None

Ceanothus megacarpus Shrubland Association

Big Pod Ceanothus Shrubland Association
***Ceanothus megacarpus* Shrubland Alliance**
Big Pod Ceanothus Shrubland Alliance

Mapping Code: 2081

Local Description

Summary:
This shrubland association occurs on moderate to steep slopes of variable aspect at low elevations between 53–730 m. It is characterized by a strong dominance of *Ceanothus megacarpus* in the shrub layer and an uncharacteristic and insignificant herbaceous layer. The emergent tree layer may include *Quercus agrifolia, Umbellularia californica,* and *Juglans californica*

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, Western Fog Zone, Eastern Urban, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 53–730 m, mean 361.9 m
Aspect: variable
Slope: range 8–45 degrees, mean 28.8 degrees
Topography (micro; macro): convex, flat, or undulating; lower slope to ridgetop
Litter Cover: range 15-50%, mean 33.8%
Small Rock Cover: range 1–50%, mean 15.3%
Large Rock Cover: range 0–15%, mean 1.9%
Bare Ground: range 0–50%, mean 21.6%
Parent Material: igneous or sedimentary
Soil Texture: medium loam to fine clay loam

Vegetation Description:
Stands of *Ceanothus megacarpus* Shrubland form an open to continuous shrub layer (16–75%, mean 53.3%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–8%, mean 0.6%) at 0–2 m tall. Trees are occasionally emergent (0–7% cover, mean 0.3%) with hardwoods at 0–10 m tall. Total vegetation cover is 19–75%, mean cover is 54.1%.

In this association, the shrub layer is dominated by *Ceanothus megacarpus. Malosma laurin*a is also characteristic but at much lower cover. *Adenostoma fasciculatum* and *Salvia mellifera* are usually included in this layer. The tree layer is emergent and open and can infrequently include *Quercus agrifolia* or *Umbellularia californica* at low cover. The herbaceous layer is diverse and sometimes includes *Marah macrocarpus, Bromus madritensis, Melica imperfecta, Centaurea melitensis, Bromus diandrus,* and *Brassica nigra*.

Comments:
In some ways this association forms the ecological core of the chaparral zone in the Santa Monica Mountains. *Ceanothus megacarpus* has its center of distribution in these mountains, and it commonly occurs in dense stands from low to moderate elevations throughout the region. This association is the relatively pure expression of the alliance where on the average *C. megacarpus* provides about 10 times the cover of all other shrub species in these stands. There is little variation in these stands and, hence, no phases have been identified.

Phases:
None

CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. It is likely to occur somewhat further north and south in south coastal California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This additional information from Borchert et al. 2004 probably largely applies to the *C. megacarpus* Association: The big pod ceanothus alliance is the dominant vegetation type on ocean-facing (south-facing) slopes of the Santa Ynez Mountains. Stands mostly occupy south-

and east-facing, upper and middle slopes between elevations of 482 and 1,023 m. Slopes generally are > 45%.

Vegetation Description:
Based on 14 plots sampled in the Santa Ynez Mountains of Santa Barbara County, Borchert et al. 2004 add this information to the local description above: Big pod ceanothus dominates this alliance with an average cover of 73%. Chamise and holly leaf cherry have constancies > 50% but their average covers are < 10%.

Comments:
See local description.

Ceanothus megacarpus-Adenostoma fasciculatum Shrubland Association

Big Pod Ceanothus-Chamise Shrubland Association
***Ceanothus megacarpus* Shrubland Alliance**
Big Pod Ceanothus Shrubland Alliance

Mapping Code: 2083

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes of variable aspect at low elevations between 0–688 m. It is characterized by the dominance of *Ceanothus megacarpus* and subdominance (averaging about half as much cover) of *Adenostoma fasciculatum* in the shrub layer. The herbaceous layer is insignificant. The emergent tree layer may infrequently include *Quercus agrifolia*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–688 m, mean 372.9 m
Aspect: variable
Slope: range 15–35 degrees, mean 26 degrees
Topography (micro; macro): undulating, convex, or flat; middle to upper slope
Litter Cover: range 10–65%, mean 41%
Small Rock Cover: range 1–50%, mean 15.5%
Large Rock Cover: range 0–8%, mean 2.8%
Bare Ground: range 10–65%, mean 24.5%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus megacarpus-Adenostoma fasciculatum* Shrubland form an open to continuous shrub layer (15–70%, mean 46.1%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–16%, mean 1.4%) at 0–1 m tall. Trees are occasionally emergent (1–5% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 20–70%, mean cover is 47.3%.

In this association, the shrub layer is characterized by *Ceanothus megacarpus, Adenostoma fasciculatum,* and *Salvia mellifera. Malosma laurina* and *Heteromeles arbutifolia* are usually included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Bromus madritensis, Piptatherum miliaceum, Centaurea melitensis, Bromus diandrus,* and *Leymus condensatus.*

Other Noteworthy Species:
Juglans californica was found in 1 of 31 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Lepechinia fragrans was found in 2 of 31 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Leptodactylon californicum was found in 1 of 31 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G5T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Piptatherum miliaceum, Bromus madritensis, Bromus diandrus, Centaurea melitensis, Avena, Brassica nigra, Carduus pycnocephalus, Euphorbia terracina, Lactuca canadensis, Nerium oleander, Brassica, Erodium, Hirschfeldia incana, Melilotus indicus

Samples Used in Description: (n = 31)

Comments:
The combination of *C. megacarpus* and *Adenostoma fasciculatum* is a common occurrence in these mountains. Two phases have been identified—one with higher cover and frequency of *Salvia mellifera*.

Phases:
Ceanothus megacarpus-Adenostoma fasciculatum (Big Pod Ceanothus-Chamise) Phase [2083]
Ceanothus megacarpus-Adenostoma fasciculatum-Salvia mellifera (Big Pod Ceanothus-Chamise-Black Sage) Phase [7083]

COMMON NAME	Big Pod Ceanothus-Chamise Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland

ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Historically, the balance between the *Adenostoma fasciculatum* (and related *Adenostoma fasciculatum* codominant alliances such as *A. fasciculatum-Salvia mellifera*) and the *Ceanothus megacarpus* Alliance may have been different. Early mapping by the U.S. Forest Service VTM crews (John Tiszler, Robert Taylor personal communication 2003) suggest that in the 1930s the predominant chaparral stands were dominated or codominated by *Adenostoma fasciculatum*. However, currently, Franklin 1998 and current mapping for this project suggest that *C. megacarpus* dominated chaparral has taken over as the principal cover. The interface of these two main dominance types occurs in associations such as this one. Thus, monitoring plots within such stands may afford a more complete understanding of overall trends of vegetation dominance within the area.

Franklin 1998

Ceanothus megacarpus-Adenostoma sparsifolium Shrubland Association

Big Pod Ceanothus-Redshank Shrubland Association
***Ceanothus megacarpus* Shrubland Alliance**
Big Pod Ceanothus Shrubland Alliance

Mapping Code: 2082

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes of variable aspect at low to mid elevations between 383–847 m. It is characterized by a dominance of *Ceanothus megacarpus* and a subdominance of *Adenostoma sparsifolium* in the shrub layer. The herbaceous layer is insignificant. The emergent tree layer is generally absent but may include *Quercus agrifolia* and *Umbellularia californica*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 383–847 m, mean 640 m
Aspect: variable
Slope: range 15–42 degrees, mean 30.6 degrees
Topography (micro; macro): undulating, convex, or flat; middle slope to ridgetop
Litter Cover: no data
Small Rock Cover: range 5–40%, mean 20%
Large Rock Cover: range 1–18%, mean 6.8%
Bare Ground: range 5–35%, mean 20.6%
Parent Material: igneous
Soil Texture: medium loam

Vegetation Description:
Stands of *Ceanothus megacarpus-Adenostoma sparsifolium* Shrubland form an open to intermittent shrub layer (31–65%, mean 48.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–4%, mean 0.7%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.3%) with hardwoods at 0–15 m tall. Total vegetation cover is 35–65%, mean cover is 49.1%.

In this association, the shrub layer is characterized by *Ceanothus megacarpus, Adenostoma sparsifolium, Malosma laurina,* and *Adenostoma fasciculatum*. *Salvia mellifera* is often present, and *Rhus ovata* is occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* and *Umbellularia californica* at low cover. The herbaceous layer is simple and sometimes includes *Bromus madritensis, Bromus hordeaceus, Centaurea melitensis, Bromus diandrus*, *Avena barbata,* and *Marah macrocarpus.*

Comments:
This association is likely to be largely endemic to the Santa Monica Mountains. Elsewhere, *A. sparsifolium* typically occurs at either more inland localities or at elevations greater than the range of *Ceanothus megacarpus.* Most of these stands occur on northerly facing steep slopes above 600 m. Mature stands tend to have a two-layered canopy with the *A. sparsifolium* projecting 1–3 m above the subcanopy of *C. megacarpus.* More recently burned stands tend to have a relatively even canopy.

Phases:
None

Ceanothus megacarpus-Cercocarpus betuloides Shrubland Association

Big Pod Ceanothus-Birch Leaf Mountain Mahogany Shrubland Association
***Ceanothus megacarpus* Shrubland Alliance**
Big Pod Ceanothus Shrubland Alliance

Mapping Code: 2084

Local Description

Summary:
This shrubland association occurs on gentle to steep northwest- and northeast-facing slopes at low elevations between 110–701 m. It is characterized by a dominance of *Ceanothus megacarpus* and a subdominance of *Cercocarpus betuloides* in the shrub layer. The herbaceous layer is generally insignificant in mature stands. The emergent tree layer is generally absent but may contain both introduced and native species.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 110–701 m, mean 370.8 m
Aspect: northwest and northeast
Slope: range 2–40 degrees, mean 25.1 degrees
Topography (micro; macro): undulating; lower to upper slope
Litter Cover: range 25–55%, mean 40%
Small Rock Cover: range 5–30%, mean 15.4%
Large Rock Cover: range 0–2%, mean 0.6%
Bare Ground: range 5–35%, mean 20.3%
Parent Material: igneous
Soil Texture: medium to moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus megacarpus-Cercocarpus betuloides* Shrubland form an open to dense shrub layer (39–65%, mean 51.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–5%, mean 0.7%) at 0–1 m tall. Trees are occasionally emergent (0–16% cover, mean 1.2%) with conifers at 0–10 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 39–65%, mean cover is 53.1%.

In this association, the shrub layer is characterized by *Ceanothus megacarpus, Cercocarpus betuloides, Adenostoma fasciculatum,* and *Heteromeles arbutifolia. Malosma laurina* and *Ceanothus spinosus* are often included in this layer. The tree layer is emergent and open and may infrequently include *Umbellularia californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and may include *Leymus condensatus, Bromus madritensis,* and *Avena* sp.

Ceanothus megacarpus-Malosma laurina Shrubland Association

Big Pod Ceanothus-Laurel Sumac Shrubland Association
***Ceanothus megacarpus* Shrubland Alliance**
Big Pod Ceanothus Shrubland Alliance

Mapping Code: 2087

Local Description

Summary:
This shrubland association occurs on gentle to very steep slopes of variable aspect at low to mid elevations between 42–780 m. It is characterized by a dominance of *Ceanothus megacarpus* and a subdominance of *Malosma laurina* in the shrub layer. The herbaceous layer is insignificant in older stands. The emergent tree layer is generally absent but can include *Quercus agrifolia*, *Umbellularia californica, Juglans californica, Pinus* sp., and *Eucalyptus* sp.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Lower Elevation Inland Santa Monica Mountains, Western Fog Zone, Immediate Coast, Simi Hills Inland, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 42–780 m, mean 395.8 m
Aspect: variable
Slope: range 2–50 degrees, mean 29.2 degrees
Topography (micro; macro): undulating; lower to upper slope
Litter Cover: range 15–60%, mean 30%
Small Rock Cover: range 2–55%, mean 19.1%
Large Rock Cover: range 0–15%, mean 2.5%
Bare Ground: range 5–65%, mean 24.6%
Parent Material: sedimentary or igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus megacarpus-Malosma laurina* Shrubland form an open to intermittent shrub layer (23–65%, mean 47.1%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0.5–10 m tall. The herbaceous layer is open (0–25%, mean 1.6%) at 0–1 m tall. Trees are occasionally emergent (0–9% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 35–65%, mean cover is 49%.

In this association, the shrub layer is characterized by *Ceanothus megacarpus* and *Malosma laurina*. *Adenostoma fasciculatum* and *Heteromeles arbutifolia* are often present, and *Salvia mellifera* is sometimes included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Marah macrocarpus, Centaurea melitensis*, *Brassica nigra, Melica imperfecta,* and *Bromus madritensis.*

Comments:
This is one of the most well sampled and most common associations in the mapping area. It is essentially a mix of two of the most abundant and characteristic shrub species of the study area. It may be broken up into several phases (see below). These are generally based on the degree of codominance or subdominance of other species such as *Adenostoma fasciculatum* with *M. laurina* and *C. megacarpus*.

Phases:
Ceanothus megacarpus-Malosma laurina (Big Pod Ceanothus-Laurel Sumac) Phase [2087]
Ceanothus megacarpus-Malosma laurina-Adenostoma fasciculatum Mixed Chaparral (Big Pod Ceanothus-Laurel Sumac-Chamise Mixed Chaparral) Phase [7081]

COMMON NAME	Big Pod Ceanothus-Laurel Sumac Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUB GROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Ceanothus megacarpus* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. It is likely to be restricted to the western transverse ranges of southern California.

Nations:
United States

States or Provinces:
CA

Ceanothus megacarpus-Salvia mellifera Shrubland Association

Big Pod Ceanothus-Black Sage Shrubland Association
***Ceanothus megacarpus* Shrubland Alliance**
Big Pod Ceanothus Shrubland Alliance

Mapping Code: 7085

Local Description

Summary:
This shrubland association occurs on gentle to very steep southwest- and southeast-facing slopes at low elevations between 49–636 m. It is characterized by *Ceanothus megacarpus* as a dominant and *Salvia mellifera* as a subdominant in the shrub layer. The herbaceous layer is insignificant. The emergent tree layer is largely absent in most stands.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Western Fog Zone, Simi Hills Inland, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 49–636 m, mean 322.7 m
Aspect: southwest and southeast
Slope: range 2–55 degrees, mean 31.3 degrees
Topography (micro; macro): variable (all); middle slope to ridgetop
Litter Cover: range 10–55%, mean 26.7%
Small Rock Cover: range 0–75%, mean 25.8%
Large Rock Cover: range 0–15%, mean 3.5%
Bare Ground: range 0–70%, mean 22.8%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus megacarpus-Salvia mellifera* Shrubland form an open to intermittent shrub layer (21–62%, mean 38.9%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–15%, mean 2.9%) at 0–1 m tall. Trees are occasionally emergent (0–5% cover, mean 0.3%) with hardwoods at 0–15 m tall. Total vegetation cover is 25–65%, mean cover is 42.2%.

In this association, the shrub layer is characterized by *Ceanothus megacarpus, Malosma laurina,* and *Salvia mellifera. Eriogonum fasciculatum, Eriogonum cinereum, Yucca whipplei,* and *Adenostoma fasciculatum* are often included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Centaurea melitensis, Bromus madritensis, Melica imperfecta, Leymus condensatus,* and *Brassica nigra*.

Other Noteworthy Species:
Juglans californica was found in 5 of 58 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Bromus madritensis, Brassica nigra, Bromus diandrus, Avena barbata, Avena, Hirschfeldia incana, Avena fatua, Piptatherum miliaceum, Bromus hordeaceus, Nicotiana glauca, Erodium cicutarium, Foeniculum vulgare, Marrubium vulgare, Schinus molle, Ageratina adenophora, Brassica, Galium aparine, Lobularia maritima, Pennisetum setaceum, Stellaria media

Samples Used in Description: (n = 58)

Ceanothus oliganthus Shrubland Association

Hairy Leaf Ceanothus Shrubland Association
***Ceanothus oliganthus* Shrubland Alliance**
Hairy Leaf Ceanothus Shrubland Alliance

Mapping Code: 2072

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low to mid elevations between 498–847 m. It is characterized by a strong dominance of *Ceanothus oliganthus* in the shrub layer, although a variety of other shrubs may occur occasionally at low cover. The emergent tree layer occasionally includes *Quercus agrifolia* and *Umbellularia californica*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 498–847 m, mean 719.8 m
Aspect: variable
Slope: range 3–35 degrees, mean 22.8 degrees
Topography (micro; macro): flat, concave, or undulating; lower to upper slope
Litter Cover: no data
Small Rock Cover: range 3–30%, mean 15.3%
Large Rock Cover: range 0–20%, mean 7.7%
Bare Ground: range 10–32%, mean 18.7%
Parent Material: igneous
Soil Texture: moderately fine silty clay loam

Vegetation Description:
Stands of *Ceanothus oliganthus* Shrubland form an intermittent to continuous shrub layer (36–65%, mean 55.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 2–5 m tall. The herbaceous layer is bare. Trees are occasionally emergent (0–12% cover, mean 3.3%) with hardwoods at 0–10 m tall. Total vegetation cover is 48–65%, mean cover is 58.8%.

In this association, the shrub layer is dominated by *Ceanothus oliganthus. Heteromeles arbutifolia* is also characteristic, but at lower cover. *Adenostoma sparsifolium* and *Quercus berberidifolia* are often present, and *Ceanothus megacarpus* is sometimes included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia and Umbellularia californica* at low cover. The herbaceous layer is simple and occasionally includes *Avena barbata, Bromus diandrus,* and *Bromus hordeaceus.*

Other Noteworthy Species:
Lepechinia fragrans was found in 3 of 10 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis

Samples Used in Description: (n = 10)
AA0056cc, AA0819, rap0265, rap0778m, rap0779m, rap0783, rap0787m, rap0789m, rap0796m, rap2382

Comments:
Ceanothus oliganthus in southern California tends to be a montane species. In the study area, it may be considered as an upper-elevation analog to *Ceanothus spinosus*, replacing it largely above 700 m. It is an obligate seeder and tends to senesce after about three to four decades (Borchert et al. 2004). This association is more common at lower elevations in the Simi Hills than in the main portion of the Santa Monica Mountains.

Phases:
None

COMMON NAME	Hairy Leaf Ceanothus Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural

ALLIANCE	*Ceanothus oliganthus* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. It is likely to occur in a number of areas from Monterey County to San Diego County but has not been adequately treated at the association level to determine its full extent.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Klein and Evens 2005, Evens and San 2005, and Borchert et al. 2004 have reported on stands of *Ceanothus oliganthus* that resemble these relatively pure stands in the SAMO study area. However, they have not had the sufficient number of stands to further differentiate their examples at the association level. Recent sampling in the peninsular ranges of San Diego County (Keeler-Wolf personal observation 2005) suggests there are other early seral postfire *Ceanothus oliganthus* associations, which may occur in mixed coniferous forests up to 1,800 m in association with emergent *Quercus chrysolepis* and *Pinus coulteri*.

Borchert et al. 2004, Evens and San 2005, Klein and Evens 2005

Ceanothus oliganthus-Adenostoma sparsifolium Shrubland Association

Hairy Leaf Ceanothus-Redshank Shrubland Association
***Ceanothus oliganthus* Shrubland Alliance**
Hairy Leaf Ceanothus Shrubland Alliance

Mapping Code: 2078

Local Description

Summary:
This shrubland association occurs on moderate to steep northwest- to southeast-facing slopes at low to mid elevations between 621–879 m. It is characterized by a codominance of *Ceanothus oliganthus* and *Adenostoma sparsifolium* in the shrub layer. The herbaceous layer is insignificant. The emergent tree layer includes *Quercus agrifolia.*

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 621–879 m, mean 744.8 m
Aspect: northwest to southeast
Slope: range 7–35 degrees, mean 22.5 degrees
Topography (micro; macro): variable (all); middle slope to ridgetop
Litter Cover: range 25–75%, mean 48.8%
Small Rock Cover: range 4–45%, mean 18.2%
Large Rock Cover: range 0–15%, mean 4.2%
Bare Ground: range 10–45%, mean 20.6%
Parent Material: igneous
Soil Texture: medium loam

Vegetation Description:
Stands of *Ceanothus oliganthus-Adenostoma sparsifolium* Shrubland form an intermittent shrub layer (38–65%, mean 50.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–2%, mean 0.4%) at 0–1 m tall. Trees are occasionally emergent (0–7% cover, mean 1.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 38–65%, mean cover is 51.9%.

In this association, the shrub layer is characterized by *Adenostoma sparsifolium* and *Ceanothus oliganthus. Adenostoma fasciculatum* are usually present, while *Ceanothus megacarpus, Quercus berberidifolia,* and *Lepechinia fragrans* are occasionally included in this layer. The tree layer is emergent and open and may occasionally include *Quercus agrifolia* and *Umbellularia californica* at low cover. The herbaceous layer is diverse and sometimes includes *Centaurea melitensis, Marah macrocarpus, Bromus madritensis*, *Melica imperfecta,* and *Leymus condensatus.*

Lepechinia fragrans was found in 11 of 23 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Bromus madritensis, Piptatherum miliaceum, Brassica nigra, Bromus hordeaceus, Bromus diandrus

Samples Used in Description: (n = 23)
AA0205cc, AA0915, AA1199, rap0262, rap0309m, rap0540, rap0616, rap0773, rap0774, rap0780, rap0788m, rap0797, rap0798, rap1491, rap1536, rap1773, rap1780, rap1783, rap1820, rap2400, rap2424, rap2800, rap2935

Comments:
Although both *A. sparsifolium* and *C. oliganthus* codominate in these stands, the ecological relationships borne out in the cluster analysis suggest this association should be classified within the *Ceanothus oliganthus* Alliance and not the *Adenostoma sparsifolium* Alliance. This is likely to be an endemic association to the Santa Monica Mountains. No other reports of this type have been alluded to in other studies of southern California chaparral. The Boney Ridge area of the high west-central portion of the study area appears to be the stronghold for this association. This is generally the only portion of the study area where elevations are high enough to support both of the characteristic species of this association. At lower elevation, *Ceanothus oliganthus* can be replaced by *Ceanothus spinosus*.

Phases:
None

Ceanothus oliganthus-Heteromeles arbutifolia-Rhus ovata Shrubland Association

Hairy Leaf Ceanothus-Toyon Shrubland Association
***Ceanothus oliganthus* Shrubland Alliance**
Hairy Leaf Ceanothus Shrubland Alliance

Mapping Code: 2076

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northeast- and northwest-facing slopes at low elevations between 336–677 m. It is characterized by the dominance of *Ceanothus oliganthus* and subdominance of *Heteromeles arbutifolia* in the shrub layer. The herbaceous layer is generally sparse. The emergent tree layer includes occasional *Juglans californica* and *Quercus agrifolia*.

Distribution:
This association is sampled in the Simi Hills, Inland Upper Elevation Santa Monica Mountains, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 336–677 m, mean 506 m
Aspect: northeast and northwest
Slope: range 15–35 degrees, mean 30.7 degrees
Topography (micro; macro): undulating or concave; lower to upper slope
Litter Cover: no data
Small Rock Cover: 5%
Large Rock Cover: no data
Bare Ground: 10%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus oliganthus-Heteromeles arbutifolia-Rhus ovata* Shrubland form an intermittent shrub layer (38–60%, mean 51.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–20%, mean 2.9%) at 0–1 m tall. Trees are occasionally emergent (0–12% cover, mean 2.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 45–63%, mean cover is 57%.

In this association, the shrub layer is characterized by *Ceanothus oliganthus*, *Heteromeles arbutifolia, Adenostoma fasciculatum,* and *Rhus ovata. Malosma laurina* and *Ceanothus crassifolius* are often included in this layer. The tree layer is emergent and open and may occasionally include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is simple and sometimes includes *Leymus condensatus, Marah macrocarpus*, *Delphinium cardinale,* and *Bromus madritensis.*

Other Noteworthy Species:
Juglans californica was found in 4 of 14 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Ailanthus altissima, Bromus madritensis, Centaurea melitensis, Robinia

Samples Used in Description: (n = 14)
AA0033cc, AA0294cc, rap0246, rap1452, rap2056, rap2093m, rap2094, rap2175m, rap2228m, rap2335, rap2356, rap2405, rap2406, rap2649

Comments:
This is the most widespread of the *Ceanothus oliganthus* associations in the study area. It is more common in the Simi Hills region but also occurs at upper elevations in the main portion of the Santa Monica Mountains. It can be considered as the mesic expression of this alliance between the relatively xeric *C. oliganthus-A. sparsifolium* and the more mesophytic *C. oliganthus-Quercus berberidifolia* associations in moisture relations.

Phases:
None

COMMON NAME	Hairy Leaf Ceanothus-Toyon Shrubland Association

Ceanothus oliganthus-Quercus berberidifolia Shrubland Association

Hairy Leaf Ceanothus-Scrub Oak Shrubland Association
***Ceanothus oliganthus* Shrubland Alliance**
Hairy Leaf Ceanothus Shrubland Alliance

Mapping Code: 2077

Local Description

Summary:
This shrubland association occurs on gentle to steep northeast- and northwest-facing slopes at low elevations between 332–729 m. It is characterized by a codominance of *Ceanothus oliganthus* and *Quercus berberidifolia* in the shrub layer. The herbaceous layer is sparse and insignificant. The emergent tree layer occasionally includes *Quercus agrifolia.*

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 332–729 m, mean 663.5 m
Aspect: northeast and northwest
Slope: range 4–35 degrees, mean 18.3 degrees
Topography (micro; macro): convex or flat; bottom to middle slope
Litter Cover: range 2–80%, mean 50.5%
Small Rock Cover: range 2–10%, mean 5.1%
Large Rock Cover: range 0–85%, mean 12.8%
Bare Ground: range 2–35%, mean 17%
Parent Material: quaternary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus oliganthus-Quercus berberidifolia* Shrubland form an open to intermittent shrub layer (10–65%, mean 49.3%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–5%, mean 0.8%) at 0–1 m tall. Trees are occasionally emergent (0–5% cover, mean 1.2%) with hardwoods at 0–15 m tall. Total vegetation cover is 12–65%, mean cover is 50.3%.

In this association, the shrub layer is characterized by *Ceanothus oliganthus. Quercus berberidifolia, Adenostoma fasciculatum, Arctostaphylos glandulosa,* and *Heteromeles arbutifolia* are often present, and *Cercocarpus betuloides* and *Ceanothus megacarpus* are occasionally included in this layer. The tree layer is emergent and open and may occasionally include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Bromus diandrus, Piptatherum miliaceum*, and *Centaurea melitensis.*

Ceanothus spinosus Shrubland Association

Greenbark Ceanothus Shrubland Association
***Ceanothus spinosus* Shrubland Alliance**
Greenbark Ceanothus Shrubland Alliance

Mapping Code: 2092

Local Description

Summary:
This shrubland association occurs on moderately steep to very steep northeast- and northwest-facing slopes at low elevations between 0–692 m. It is characterized by a strong dominance of *Ceanothus spinosus* in the shrub layer and may include a wide variety of mesophytic species in the herbaceous layer, none apparently in high constancy. The emergent tree layer includes *Quercus agrifolia* and *Juglans californica.*

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–692 m, mean 385.5 m
Aspect: northeast and northwest
Slope: range 10–48 degrees, mean 29.8 degrees
Topography (micro; macro): concave, convex, or flat; lower to upper slope
Litter Cover: range 25–70%, mean 51.4%
Small Rock Cover: range 0–35%, mean 9.9%
Large Rock Cover: range 0–15%, mean 1.6%
Bare Ground: range 0–75%, mean 18.2%
Parent Material: sedimentary or igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus spinosus* Shrubland form an open to continuous shrub layer (10–68%, mean 53.6%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–10 m tall. The herbaceous layer is open to intermittent (0–57%, mean 3.4%) at 0–2 m tall. Trees are occasionally emergent (0–45% cover, mean 2%) with conifers at 0–10 m tall and hardwoods at 0–15 m tall. Total vegetation cover is 38–70%, mean cover is 58.1%.

In this association, the shrub layer is dominated by *Ceanothus spinosus. Heteromeles arbutifolia* is also characteristic but at lower cover. *Malosma laurina* and *Ceanothus megacarpus* are often present, while *Rhus ovata* is occasionally included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia, Juglans californica,* and *Umbellularia californica* at low cover. The herbaceous layer is diverse and sometimes includes *Leymus condensatus, Marah macrocarpus, Melica imperfecta,* and *Bromus diandrus.*

***Ceanothus spinosus* Association**

Comments:
This is an abundant association in the study area. Although typical of concave north-facing slopes at mid and lower elevations, it may also occur on drier exposures closer to the coast where summer fog may ameliorate evapotranspiration. This relatively tall, arborescent chaparral association often occurs adjacent to stands of *Quercus agrifolia, Juglans californica*, or even riparian woodlands, suggesting a relatively high moisture regime. Three phases have been identified that suggests relatively more (*Ceanothus spinosus-Heteromeles arbutifolia-Prunus ilicifolia)* or less *(Ceanothus spinosus-Malosma laurina*) mesic settings. The association with *Malosma laurina* may also indicate increased fire frequency.

Phases:
Ceanothus spinosus (Greenbark Ceanothus) Phase [2092]
Ceanothus spinosus-Heteromeles arbutifolia-Prunus ilicifolia (Greenbark Ceanothus-Toyon-Holly Leaf Cherry) Phase [2094]
Ceanothus spinosus-Malosma laurina (Greenbark Ceanothus-Laurel Sumac) Phase [2097]

COMMON NAME	Greenbark Ceanothus Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Ceanothus spinosus* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
Based on the similarities of this association with the alliance description in Borchert et al. 2004, we can extrapolate the following from their general description and state: The greenbark ceanothus alliance is prominent on north-facing slopes, although it also occurs on ocean-facing slopes. Most stands occupy mesic (solar insolation < 200), moderately steep (> 50%) slopes on a variety of exposures, although north-facing aspects are most common.

Vegetation Description:
The following information has been excerpted from Borchert et al. 2004 in their description of the alliance in the Santa Ynez Mountains: Although greenbark ceanothus clearly dominates this alliance, holly leaf cherry *(Prunus ilicifolia)* and toyon *(Heteromeles arbutifolia)* are almost always associated with it, indicating that these species form a plant association within the greenbark ceanothus alliance. Co-occurring species in this alliance may be different on ocean-facing slopes of the Santa Ynez Mountains.

Comments:
Based on the comments of Borchert et al. 2004, it is likely that this association is the principal one found in the Santa Monica Mountains and in the Santa Ynez Mountains to the north and west of this study area. Although *Heteromeles arbutifolia* is a common associate of this association, it was not found to be a strong enough indicator to warrant an entire association. A *Ceanothus spinosus-Heteromeles arbutifolia-Prunus ilicifolia* phase of this association has been identified, which is analogous to the situation described by Borchert et al. 2004 above.

Borchert et al. 2004

Ceanothus spinosus-Ceanothus megacarpus Shrubland Association

Greenbark Ceanothus-Big Pod Ceanothus Shrubland Association
***Ceanothus spinosus* Shrubland Alliance**
Greenbark Ceanothus Shrubland Alliance

Mapping Code: 2091

Local Description

Summary:
This shrubland association occurs on moderately steep to steep northeast- and northwest-facing slopes at low elevations between 0–749 m. It is characterized by a codominance of *Ceanothus spinosus* and *C. megacarpus* in the shrub layer. The herbaceous layer is diverse but has no constant indicators and generally provides little cover. The emergent tree layer includes occasional *Quercus agrifolia* and *Juglans californica.*

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Lower Elevation Inland Santa Monica Mountains, Immediate Coast, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–749 m, mean 395 m
Aspect: northeast and northwest
Slope: range 10–40 degrees, mean 32.9 degrees
Topography (micro; macro): undulating; lower to upper slope
Litter Cover: range 25–60%, mean 48.3%
Small Rock Cover: range 5–45%, mean 14.9%
Large Rock Cover: range 0–7%, mean 2.2%
Bare Ground: range 7–45%, mean 21%
Parent Material: igneous or sedimentary
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Ceanothus spinosus-Ceanothus megacarpus* Shrubland form an open to continuous shrub layer (32–66%, mean 53.3%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–25%, mean 1.7%) at 0–2 m tall. Trees are occasionally emergent (0–11% cover, mean 1.5%) with conifers at 0–15 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 40–67%, mean cover is 56.2%.

In this association, the shrub layer is characterized by *Ceanothus spinosus, Ceanothus megacarpus,* and *Malosma laurina*. *Heteromeles arbutifolia* is often present, and *Rhus ovata* is occasionally included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Melica imperfecta, Leymus condensatus, Brassica nigra, Marah macrocarpus,* and *Bromus madritensis.*

Comments:
In this association, the two principal members of the two main chaparral alliances endemic to the western transverse ranges comingle. Because *C. megacarpus* is typical of relatively xeric settings and *C. spinosus* is conversely typical of mesic settings, it stands to reason that this mixing of the two species falls in between. Thus, although the stands of this association tend to occur on northerly facing slopes, they usually occur on the upper slopes, toward the ridges and on minor convexities. Either species of *Ceanothus* may dominate with more than twice the cover of the other, although *C. spinosus* is more frequently dominant.

Phases:
None

Cercocarpus betuloides Shrubland Association

Birch Leaf Mountain Mahogany Shrubland Association
***Cercocarpus betuloides* Shrubland Alliance**
Birch Leaf Mountain Mahogany Shrubland Alliance

Mapping Code: 2114

Local Description

Summary:
This shrubland association occurs on moderately steep to steep northeast- and northwest-facing slopes at low elevations between 10–661 m. It is characterized by a dominance of *Cercocarpus betuloides* in the shrub layer. The herbaceous layer has no characteristic species. The emergent tree layer may include infrequent *Quercus agrifolia, Juglans californica, Platanus racemosa,* and *Umbellularia californica*.

Distribution:
This association is sampled in the Immediate Coast, Western Fog Zone, Eastern Urban, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 10–661 m, mean 233.5 m
Aspect: northeast and northwest
Slope: range 8–8 degrees, mean 31.3 degrees
Topography (micro; macro): variable (all); lower to upper slope
Litter Cover: range 55–65%, mean 59.3%
Small Rock Cover: range 0–15%, mean 8.8%
Large Rock Cover: range 0–12%, mean 3.4%
Bare Ground: range 0–55%, mean 19.7%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Cercocarpus betuloides* Shrubland form an open to continuous shrub layer (16–68%, mean 46.7%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–28%, mean 4%) at 0–2 m tall. Trees are occasionally emergent (0–7% cover, mean 0.8%) with hardwoods at 0–10 m tall. Total vegetation cover is 37–70%, mean cover is 51.1%.

In this association, the shrub layer is dominated by *Cercocarpus betuloides. Heteromeles arbutifolia* is also characteristic but at lower cover. *Malosma laurina* is often present, while *Ceanothus spinosus* and *Ceanothus megacarpus* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Leymus condensatus, Melica imperfecta, Marah macrocarpus, Phacelia* sp., *Nassella* sp., and *Bromus diandrus.*

Other Noteworthy Species:
Calochortus plummerae was found in 1 of 42 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 5 of 42 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Lepechinia fragrans was found in 1 of 42 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Woodwardia fimbriata was found in 2 of 42 surveys of this plant community. Regionally, the park considers this species as Locally Rare. CNPS ranks this species as none, CNPS R-E-D Code is 0-0-0. Global rank is none, and state rank is none (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Bromus diandrus, Bromus hordeaceus, Centaurea melitensis, Avena fatua, Bromus madritensis, Piptatherum miliaceum, Hirschfeldia incana, Avena barbata, Capsella bursa-pastoris, Carduus pycnocephalus, Erodium, Malva parviflora, Nicotiana glauca, Ricinus communis, Stellaria media, Ageratina adenophora, Bromus tectorum, Cistus, Galium aparine, Marrubium vulgare

Samples Used in Description: (n = 42)

Comments:
This is the most widespread of the four associations of *Cercocarpus betuloides* in the study area. It is often found on steep, usually upper northerly facing slopes.

Phases:
None

COMMON NAME	Birch Leaf Mountain Mahogany Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Cercocarpus betuloides* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains and western Riverside County (Klein and Evens 2005). Information about its global distribution is not available without additional inventory; however, it is likely to occur more widely throughout California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
Cercocarpus betuloides is usually the dominant species in the shrub overstory. A variety of shrubs consistently intermix as subdominants including *Heteromeles arbutifolia*, *Ceanothus crassifolius*, *Rhamnus ilicifolia*, *Prunus ilicifolia*, and *Salvia mellifera*. Other species that commonly occur at low cover include the shrub *Adenostoma fasciculatum* and herb *Dudleya pulverulenta* (in western Riverside County).

Comments:
This association appears to be widespread throughout coastal California and may also range into the foothills of the Sierra Nevada (Keeler-Wolf, personal observation).

Klein and Evens 2005

Cercocarpus betuloides-Adenostoma fasciculatum Shrubland Association

Birch Leaf Mountain Mahogany-Chamise Shrubland Association
***Cercocarpus betuloides* Shrubland Alliance**
Birch Leaf Mountain Mahogany Shrubland Alliance

Mapping Code: 2115

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northwest-facing slopes at low elevations between 154–618 m. It is characterized by a codominance of *Cercocarpus betuloides* and *Adenostoma fasciculatum* in the shrub layer. *Melica imperfecta* occurs regularly in many of the stands at low cover in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia*.

Distribution:
This association is sampled in the Eastern Urban, Upper Elevation Santa Monica Mountains, Simi Hills Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 154–618 m, mean 315.5 m
Aspect: northwest
Slope: range 15–40 degrees, mean 32.5 degrees
Topography (micro; macro): variable (all); middle to upper slope
Litter Cover: range 8–55%, mean 31.5%
Small Rock Cover: range 8–35%, mean 20.6%
Large Rock Cover: range 0–15%, mean 4.2%
Bare Ground: range 15–32%, mean 22.4%
Parent Material: igneous
Soil Texture: medium to moderately fine clay loam

Vegetation Description:
Stands of *Cercocarpus betuloides-Adenostoma fasciculatum* Shrubland form an intermittent shrub layer (35–52%, mean 43.7%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–20%, mean 4.9%) at 0–2 m tall. Trees are occasionally emergent (0–4% cover, mean 0.9%) with hardwoods at 0–10 m tall. Total vegetation cover is 35–60%, mean cover is 49.8%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum, Cercocarpus betuloides, Heteromeles arbutifolia,* and *Malosma laurina*. *Salvia mellifera* is often present and *Quercus berberidifolia* is occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and may include *Melica imperfecta, Phacelia* sp., *Brassica nigra, Bromus madritensis, Bromus diandrus, Marah macrocarpus,* and *Centaurea melitensis.*

Comments:
This association occurs often at the head of small ravines and canyons on northerly exposures where there is an intermediate set of moisture conditions between convex and concave topography that allows a blending of the two dominant shrubs.

Phases:
None

COMMON NAME	Birch Leaf Mountain Mahogany-Chamise Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Cercocarpus betuloides* Shrubland Alliance

CLASSIFICATION CONFIDENCE LEVEL 1

ECOLOGICAL REGIONS 261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains

CONSERVATION STATUS RANK G4S4

Global Description

Distribution:
This association is also known from other regions of southern California including western San Gabriel and San Bernardino mountains, the San Jacinto Mountains, and the southern peninsular ranges as well as the Santa Monica Mountains.

Nations:
United States

States or Provinces:
CA

Environmental Description:
Elsewhere it occurs on low to moderately high elevations on moderately steep to steep, southeast- to northeast-facing slopes. Geologic substrate is usually granitic and the soil group is usually alfisols.

Vegetation Description:
Elsewhere it is similar to above local description. The two main species of the association are regularly codominant, and there is usually some *Eriogonum fasciculatum* present (Gordon and White 1994).

Comments:
Interestingly, two recent studies of the vegetation of western Riverside County (Klein and Evens 2005) and San Dieguito River watershed (Evens and San 2005) failed to find this particular association.

References:
Evens and San 2005, Gordon and White 1994, Klein and Evens 2005

Cercocarpus betuloides-Ceanothus spinosus Shrubland Association

Birch Leaf Mountain Mahogany-Greenbark Ceanothus Shrubland Association
***Cercocarpus betuloides* Shrubland Alliance**
Birch Leaf Mountain Mahogany Shrubland Alliance

Mapping Code: 2113

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northwest-facing slopes at low elevations between 64–526 m. It is characterized by a codominance of *Cercocarpus betuloides* and *Ceanothus spinosus* in the shrub layer and an insignificant herbaceous layer with occasional *Leymus condensatus.* The emergent tree layer includes occasional *Quercus agrifolia* and rarely *Juglans californica* and *Platanus racemosa*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 64–526 m, mean 317 m
Aspect: northwest
Slope: range 15–45 degrees, mean 31.3 degrees
Topography (micro; macro): undulating or flat; middle to upper slope
Litter Cover: range 50–70%, mean 60%
Small Rock Cover: range 2–18%, mean 8.3%
Large Rock Cover: range 0–8%, mean 2%
Bare Ground: range 12–42%, mean 22.8%
Parent Material: igneous or sedimentary
Soil Texture: medium loam

Vegetation Description:
Stands of *Cercocarpus betuloides-Ceanothus spinosus* Shrubland form an open to intermittent shrub layer (29–60%, mean 52.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 2–5 m tall. The herbaceous layer is open (0–7%, mean 1.9%) at 0–1 m tall. Trees are occasionally emergent (0–21% cover, mean 2.1%) with hardwoods at 0–15 m tall. Total vegetation cover is 47–65%, mean cover is 55.3%.

In this association, the shrub layer is characterized by *Ceanothus spinosus, Cercocarpus betuloides,* and *Prunus ilicifolia. Heteromeles arbutifolia, Malosma laurina, Ceanothus megacarpus,* and *Adenostoma fasciculatum* are usually included in this layer. The tree layer is emergent and open and may occasionally include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Leymus condensatus*, *Bromus diandrus,* and *Melica imperfecta.*

Comments:
This is the local mesic version of the *Cercocarpus betuloides* Alliance. Its environmental position is typically on concave slopes adjacent to the more mesic *Ceanothus spinosus* Alliance stands but typically at higher-slope positions. It represents a more mesic setting than the *C. betuloides* Association and is significantly more mesic than the *C. betuloides-Adenostoma fasciculatum* Association. All the local *Cercocarpus betuloides* Associations in the SAMO study area tend to occur in small stands in intermediate positions between other more widespread alliances such as *Ceanothus megacarpus, C. spinosus,* or *Adenostoma fasciculatum* Alliance stands.

Further detailed description of the understory of this and other steep mesophytic stands of chaparral would likely reveal more species of shared herbs and grasses such as *Melica imperfecta*.

Phases:
None

Cercocarpus betuloides-Malosma laurina-Artemisia californica Shrubland Association

Birch Leaf Mountain Mahogany-Laurel Sumac-California Sagebrush Shrubland Association
***Cercocarpus betuloides* Shrubland Alliance**
Birch Leaf Mountain Mahogany Shrubland Alliance

Mapping Code: 2117

Local Description

Summary:
This shrubland association occurs on moderately steep to very steep northeast-facing slopes at low elevations between 33–743 m. It is characterized by dominance of *Cercocarpus betuloides* and subdominance to codominance of *Malosma laurina* in the shrub layer. *Melica imperfecta* and scattered other native and nonnative species are present in the herbaceous layer. The emergent tree layer includes infrequent *Quercus agrifolia* and *Umbellularia californica*.

Distribution:
This association is sampled in the Immediate Coast, Eastern Urban, Upper Elevation Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 33–743 m, mean 177.5 m
Aspect: northeast
Slope: range 12–48 degrees, mean 34.1 degrees
Topography (micro; macro): flat or convex; lower to upper slope
Litter Cover: no data
Small Rock Cover: range 3–55%, mean 18.3%
Large Rock Cover: range 0–85%, mean 12.4%
Bare Ground: range 2–40%, mean 23.1%
Parent Material: sedimentary or quaternary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Cercocarpus betuloides-Malosma laurina-Artemisia californica* Shrubland form an open to intermittent shrub layer (17–51%, mean 37.3%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–19%, mean 6.1%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 17–55%, mean cover is 42.8%.

In this association, the shrub layer is characterized by *Cercocarpus betuloides, Malosma laurina*, *Heteromeles arbutifolia,* and *Artemisia californica. Salvia mellifera* and *Eriogonum cinereum* are often present, while *Mimulus aurantiacus* is occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Umbellularia californica* at low cover. The herbaceous layer is diverse and sometimes includes *Melica imperfecta, Leymus condensatus, Bromus madritensis, Avena fatua, Foeniculum vulgare, Brassica nigra,* and *Marah macrocarpus.*

	LECO12	*Leymus condensatus*	33	1.0	1.0	8.0			
	POACXX	*Poaceae*	20	0.9	0.2	8.0			
	BRMA3	*Bromus madritensis*	20	0.3	0.2	4.0		X	

Other Noteworthy Species:
Juglans californica was found in 1 of 15 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Bromus madritensis, Avena, Avena fatua, Brassica nigra, Foeniculum vulgare, Senecio mikanioides, Schinus molle, Nerium oleander, Conium maculatum, Hirschfeldia incana, Ailanthus altissima, Centaurea melitensis, Erodium, Euphorbia terracina, Nicotiana glauca, Pennisetum setaceum, Piptatherum miliaceum

Samples Used in Description: (n = 15)
AA0010cc, AA0185cc, AA0926, rap0163, rap0166, rap0273, rap0919, rap0928, rap1052, rap1116, rap1181m, rap1192m, rap1865m, rap2167m, rap2644

Comments:
This is a low elevation, largely coastal association that likely does not range much beyond the SAMO study area and the western transverse ranges. It typically occurs on northerly facing slopes immediately adjacent to coastal scrub alliances such as the *Artemisia californica* Alliance. These stands are usually well within the coastal summer fog zone. Two phases have been defined, one with relatively more *Malosma laurina* and the other with relatively more *A. californica*.

Phases:
Cercocarpus betuloides-Malosma laurina-Artemisia californica (Birch Leaf Mountain Mahogany-Laurel Sumac) Phase [2117]
Cercocarpus betuloides-Artemisia californica/Melica imperfecta (Birch Leaf Mountain Mahogany-California Sagebrush [Provisional]) Phase [2111]

COMMON NAME	Birch Leaf Mountain Mahogany-Laurel Sumac-California Sagebrush Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Cercocarpus betuloides* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Coreopsis gigantea-Artemisia californica-Eriogonum cinereum Shrubland Association

Giant Coreopsis-California Sagebrush-Ashy Buckwheat Shrubland Association
***Coreopsis gigantea* Shrubland Alliance**
Giant Coreopsis Shrubland Alliance

Mapping Code: 3345

Local Description

Summary:
This shrubland association occurs on flat to very steep southwest- to northeast-facing slopes at low elevations between 1–407 m. It is characterized by a dominance of *Coreopsis gigantea* with a co- or subdominance of *Artemisia californica* and *Eriogonum cinereum* in the shrub layer. The herbaceous layer may have low cover of *Leymus condensatus*, *Melica imperfecta,* and scattered nonnative species. The emergent tree layer is typically absent but may include nonnative species.

Distribution:
This association is sampled in the Immediate Coast and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 1–407 m, mean 51.1 m
Aspect: southwest to northeast
Slope: range 0–60 degrees, mean 34.4 degrees
Topography (micro; macro): undulating or flat; bottom to middle slope
Litter Cover: range 5–15%, mean 10%
Small Rock Cover: range 10–50%, mean 28.5%
Large Rock Cover: range 0–30%, mean 6%
Bare Ground: range 8–50%, mean 32.8%
Parent Material: quaternary or igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Coreopsis gigantea-Artemisia californica-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (14–48%, mean 28.3%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–30%, mean 8.4%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.1%) with conifers at 0–15 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 23–55%, mean cover is 36.4%.

In this association, the shrub layer is characterized by *Coreopsis gigantea, Artemisia californica, Rhus integrifolia,* and *Eriogonum cinereum*. *Yucca whipplei, Encelia californica, Malosma laurina,* and *Isomeris arborea* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Eucalyptus* sp. and *Pinus* sp. at low cover. The herbaceous layer is diverse and may include *Leymus condensatus, Melica imperfecta, Foeniculum vulgare, Bromus madritensis*, *Carpobrotus edulis,* and *Brassica nigra.*

Other Noteworthy Species:
Erysimum insulare was found in 1 of 21 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Foeniculum vulgare, Bromus madritensis, Carpobrotus edulis, Brassica nigra, Pennisetum setaceum, Carpobrotus chilensis, Salsola tragus, Nicotiana glauca, Cortaderia, Malva parviflora, Mesembryanthemum crystallinum, Bromus diandrus, Eucalyptus, Medicago polymorpha, Melilotus indicus, Myoporum laetum, Brassica, Cakile maritima, Erodium cicutarium, Hirschfeldia incana, Marrubium vulgare, Oxalis pes-caprae, Raphanus sativus, Sonchus oleraceus

Samples Used in Description: (n = 21)
AA0869, AA1058, AA1059, AA1062, AA1063, rap0520, rap0639, rap0645, rap0666, rap0903, rap0907, rap0938, rap1045, rap1156, rap1201, rap1273, rap1276, rap2818, rap2887rlv, rap2888rlv, rap2889rlv

Comments:
This is an association restricted to the immediate coast, usually on steep bluffs or stable slopes within a kilometer of the ocean. The dominant species is a drought-deciduous soft woody shrub, which is very frost sensitive. *Coreopsis gigantea* is an indicator and may not always be a dominant. Due to the withering nature of *C. gigantea* in the later summer and fall months, these stands appear to have much higher relative cover of the codominant shrubs.

Phases:
None

COMMON NAME Giant Coreopsis-California Sagebrush-Ashy Buckwheat Shrubland Association

Coreopsis gigantea-Ericameria ericoides-Encelia californica Shrubland Association

Giant Coreopsis-Dune Goldenbush-California Encelia Shrubland Association
***Coreopsis gigantea* Shrubland Alliance**
Giant Coreopsis Shrubland Alliance

Mapping Code: 3342

Local Description

Summary:
This shrubland association occurs on gentle to steep northeast-facing slopes at low elevations between 0–40 m. It is characterized by a codominance of *Coreopsis gigantea* and *Ericameria ericoides* in the shrub layer and a variety of psammophytic coastal species in the herbaceous layer. The emergent tree layer is absent.

Distribution:
This association is sampled in the Immediate Coast and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–40 m, mean 21.3 m
Aspect: northeast or flat
Slope: range 0–35 degrees, mean 9.5 degrees
Topography (micro; macro): flat or undulating; lower slope to ridgetop
Litter Cover: range 35–60%, mean 47.5%
Small Rock Cover: range 0–10%, mean 3.7%
Large Rock Cover: range 0–5%, mean 0.6%
Bare Ground: range 20–80%, mean 48.4%
Parent Material: quaternary
Soil Texture: coarse to medium loamy sand

Vegetation Description:
Stands of *Coreopsis gigantea-Ericameria ericoides-Encelia californica* Shrubland form an open to intermittent shrub layer (2–60%, mean 24.2%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–2 m tall. The herbaceous layer is open to intermittent (0–41%, mean 10.6%) at 0–1 m tall. Trees are not present. Total vegetation cover is 17–60%, mean cover is 34.9%.

In this association, the shrub layer is characterized by *Coreopsis gigantea, Encelia californica,* and *Ericameria ericoides. Opuntia littoralis* is often present and *Rhus integrifolia* is occasionally included in this layer. The tree layer is absent. The herbaceous layer is diverse and occasionally includes *Croton californicus, Eschscholzia californica, Carpobrotus edulis,* and *Marah macrocarpus.*

Comments:
This is a rare and local vegetation type known mostly from the Point Dume area and scattered bluffs westward to Point Mugu. The scattered bluffs, however, do not have *Ericameria ericoides.* Similar stands may exist as far north as San Luis Obispo County at places such as the Nipomo Dunes, although they have not been confirmed elsewhere. Recent removal of *Carpobrotus edulis* for the Point Dume stands should be monitored to ensure protection from reinvasion and human trampling.

Dendromecon rigida Shrubland Alliance

Bush Poppy Shrubland Alliance

Mapping Code: 3350

Local Description

Summary:
This shrubland alliance occurs on moderately steep to steep northwest- or southeast-facing slopes at low elevations between 0–673 m. It is dominated by *Dendromecon rigida* in the shrub layer. All Santa Monica Mountains stands so far have a constant low cover of *Heteromeles arbutifolia,* and *Adenostoma fasciculatum* is also found in more than 80% of the stands. The emergent tree layer includes occasional *Quercus agrifolia*.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 0–673 m, mean 385.2 m
Aspect: northwest and southeast
Slope: range 12–35 degrees, mean 25 degrees
Topography (micro; macro): flat to undulating; mid to upper slope
Litter Cover: no data
Small Rock Cover: range 4–15%, mean 9.5%
Large Rock Cover: range 1–2%, mean 1.5%
Bare Ground: range 15–20%, mean 17.5%
Parent Material: sedimentary or quaternary
Soil Texture: moderately fine silty clay loam

Vegetation Description:
Stands of this shrubland alliance form an open to intermittent shrub layer (32–57%, mean 40.2%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–1%, mean 0.2%) at 0–1 m tall. Trees are occasionally emergent (0–15% cover, mean 3%) with hardwoods at 0–10 m tall. Total vegetation cover is 32–58%, mean cover is 42.5%.

In this association, the shrub layer is characterized by *Dendromecon rigida, Heteromeles arbutifolia*, and *Adenostoma fasciculatum*. *Malosma laurina, Rhus ovata, Quercus berberidifolia*, *Ceanothus spinosus,* and *Prunus ilicifolia* are occasionally included in this layer. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and is characterized by *Poaceae* sp.

Nonnative Species:
Eucalyptus

Samples Used in Description: (n = 6)
AA0334, rap0252, rap0263m, rap2665, rap2761, rap2919

Comments:
This is a typically ephemeral, postfire vegetation alliance. It has not been sampled extensively except in this study. It forms short-lived stands in burned chaparral that appear to exist about 10 years or less. The seeds are long lived. Over a period of several years, *Dendromecon* is replaced by resprouting shrubs of *Adenostoma* sp., *Heteromeles arbutifolia, Malosma laurina, Rhus ovata*, and seedlings of other species of longer-lived shrubs such as *Ceanothus megacarpus*.

Phases:
None

COMMON NAME	Bush Poppy Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland

PHYSIOGNOMIC SUBGROUP	III.A.2.N. Natural/Seminatural
FORMATION	III.A.2.N.a. Temperate broad-leaved evergreen shrubland
ALLIANCE	*Dendromecon rigida* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. However, it is likely that with widespread sampling throughout its California range, the *D. rigida* Alliance will be found throughout California from Shasta County to San Diego County.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Stands with *Dendromecon rigida* occur in many chaparral types following fire. In Yosemite National Park (Keeler-Wolf et al. 2003), stands with *D. rigida* were considered an association of the *Adenostoma fasciculatum* Alliance. It remains to be seen if analogs to the strongly dominated *D. rigida* stands in the Santa Monica Mountains will be found elsewhere in California.

References:
Keeler-Wolf et al. 2003

Encelia californica Shrubland Association

California Encelia Shrubland Association
***Encelia californica* Shrubland Alliance**
California Encelia Shrubland Alliance

Mapping Code: 3222

Local Description

Summary:
This shrubland association occurs on gentle to steep southwest- and southeast-facing slopes at low elevations between 2–496 m. It is characterized by strong dominance of *Encelia californica* in the shrub layer and a scattering of mostly nonnative species in the herbaceous layer. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Immediate Coast, Dry Inland, Western Fog Zone, Upper Elevation Santa Monica Mountains, Eastern Urban, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 2–496 m, mean 205.8 m
Aspect: southwest and southeast
Slope: range 0–38 degrees, mean 24.4 degrees
Topography (micro; macro): undulating, flat, or convex; lower to upper slope
Litter Cover: range 10–75%, mean 38.9%
Small Rock Cover: range 0–65%, mean 16%
Large Rock Cover: range 0–10%, mean 0.9%
Bare Ground: range 0–55%, mean 31.4%
Parent Material: sedimentary
Soil Texture: moderately fine to fine clay loam

Vegetation Description:
Stands of *Encelia californica* Shrubland form an open to continuous shrub layer (12–69%, mean 34.8%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–31%, mean 4.7%) at 0–1 m tall. Trees are occasionally emergent (0–12% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 24–70%, mean cover is 39.8%.

In this association, the shrub layer is characterized by abundant *Encelia californica*. *Artemisia californica* and *Malosma laurina* are usually present, while *Salvia mellifera* and *Yucca whipplei* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and often includes *Brassica nigra*. *Bromus madritensis, Leymus condensatus,* and *Centaurea melitensis* are sometimes present.

AA0372cc, AA0373cc, AA0497, AA0615, AA0976, AA0995, AA1097, AA1111, rap0036, rap0330, rap0334, rap0623, rap0657, rap0915, rap0923, rap0926, rap0934, rap0972, rap0981, rap1047, rap1063, rap1269, rap1420, rap1421m, rap1463, rap1525, rap1596, rap1598, rap1638, rap1745, rap1794, rap1830, rap1837, rap1851, rap1963, rap2046, rap2051, rap2514, rap2755, rap2816, rap2869rlv, rap2905rlv

Comments:
This is the standard version of the *Encelia californica* Alliance in the study area. As with other examples of this alliance defined elsewhere, it typically contains a relatively large nonnative herbaceous component with evidence of recent disturbance from fire or clearing. *E. californica* seems to require disturbance of this type to maintain stands over time. Otherwise, it may succeed to more stable versions of coastal scrub such as associations in the *Artemisia californica, Salvia leucophylla, Salvia mellifera,* or *Eriogonum cinereum* Alliances. Two phases

have been identified, one with essentially pure dominance of *E. californica* and the other with a mixture of *Eriogonum fasciculatum* and *Encelia californica*.

Phases:
Encelia californica (California Encelia) Phase [3222]

ALLIANCE	*Encelia californica* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Other studies of this alliance (Klein and Evens 2005, Evens and San 2005) have not defined this association. They do describe similar associations but with a mixture of *Encelia californica* and *Artemisia californica*.

Evens and San 2005, Klein and Evens 2005

Encelia californica-Artemisia californica Shrubland Association

California Encelia-California Sagebrush Shrubland Association
***Encelia californica* Shrubland Alliance**
California Encelia Shrubland Alliance

Mapping Code: 3227

Local Description

Summary:
This shrubland association occurs on gentle to very steep southwest-and southeast-facing slopes at low elevations between 3–423 m. It is characterized by a codominance of *Encelia californica* and *Artemisia californica* in the shrub layer and a largely nonnative herbaceous layer characterized by *Brassica nigra*. The emergent tree layer includes *Juglans californica* and *Sambucus mexicana*.

Distribution:
This association is sampled in the Eastern Urban, Immediate Coast, Dry Inland, Lower Elevation Inland Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 3–423 m, mean 211 m
Aspect: southwest and southeast
Slope: range 2–50 degrees, mean 27.1 degrees
Topography (micro; macro): variable (all); middle to upper slope
Litter Cover: range 35–55%, mean 45%
Small Rock Cover: range 5–40%, mean 20.7%
Large Rock Cover: range 0–15%, mean 1.9%
Bare Ground: range 10–65%, mean 33.5%
Parent Material: sedimentary or quaternary
Soil Texture: moderately fine to fine silty or sandy clay loam

Vegetation Description:
Stands of *Encelia californica-Artemisia californica* Shrubland form an open to intermittent shrub layer (5–47%, mean 28.9%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (1–25%, mean 10.5%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 15–52%, mean cover is 39.6%.

In this association, the shrub layer is characterized by *Encelia californica* and *Artemisia californica. Malosma laurina* and *Salvia mellifera* are often present, while *Sambucus mexicana* and *Baccharis pilularis* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is diverse and is characterized by *Brassica nigra*. Other herbs sometimes include *Marah macrocarpus, Marrubium vulgare, Bromus diandrus,* and *Leymus condensatus.*

Other Noteworthy Species:
Stanleya pinnata was found in 1 of 14 surveys of this plant community. Regionally, the park considers this species as Locally Rare. This species is not listed by CNPs. Global rank is none, and state rank is none (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 3 of 14 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Brassica nigra, Bromus diandrus, Marrubium vulgare, Bromus madritensis, Erodium, Nicotiana glauca, Medicago polymorpha, Hirschfeldia incana, Centaurea melitensis, Foeniculum vulgare, Melilotus indicus, Myoporum laetum, Euphorbia terracina, Carpobrotus chilensis, Arundo donax, Cakile maritima, Carpobrotus edulis, Galium aparine, Malva parviflora, Pennisetum setaceum, Salsola tragus, Schinus molle, Brassica, Conium maculatum, Erodium cicutarium, Ricinus communis

Samples Used in Description: (n = 14)

Comments:
This association is less common than the *Encelia californica* Association. It is generally only differentiated from the former association by the codominance of *A. californica* and *E. californica*. This association tends to reflect more stable conditions with less recent disturbance than the former type.

Phases:
None

COMMON NAME	California Encelia-California Sagebrush Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland

ALLIANCE	*Encelia californica* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains as well as other parts of south coastal California including western Riverside and San Diego counties. Malanson 1984 also describes this association from southern California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
In western Riverside County and San Diego County, stands are found on gentle to somewhat steep slopes at low elevations (below 1,000 m). The ground typically has a moderate to high amount of rock cover and bare exposed soil. Parent material is often granite, less often sedimentary. Soil texture is usually sandy loam.

Vegetation Description:
In western Riverside County (Klein and Evens 2005), *Artemisia californica* is either codominant or subdominant. Other shrubs may intermix at low cover, the most common species being

Eriogonum fasciculatum, *Opuntia parryi*, and *Lessingia filaginifolia*. A variety of native and nonnative forbs and grasses occupies the herb understory. In San Diego County (Evens and San 2005), *Encelia californica* and *Artemisia californica* are codominant in the shrub layer. *Hirschfeldia incana* or *Bromus madritensis* may dominate the herbaceous layer.

Comments:
None

Encelia californica-Eriogonum cinereum Shrubland Association

California Encelia-Ashy Buckwheat Shrubland Association
***Encelia californica* Shrubland Alliance**
California Encelia Shrubland Alliance

Mapping Code: 3225

Local Description

Summary:
This shrubland association occurs on somewhat steep to very steep southeast- and southwest-facing slopes at low elevations between 0–259 m. It is characterized by a codominance of *Encelia californica* and *Eriogonum cinereum* in the shrub layer. As with other associations of this alliance, the herbaceous layer tends to have relatively high frequencies of *Brassica nigra* and other nonnatives. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Western Fog Zone and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 0–259 m, mean 102.9 m
Aspect: southeast and southwest
Slope: range 15–55 degrees, mean 27.2 degrees
Topography (micro; macro): undulating, convex, or flat; lower slope to ridgetop
Litter Cover: range 15–35%, mean 27.5%
Small Rock Cover: range 0–40%, mean 15.8%
Large Rock Cover: range 0–30%, mean 3.9%
Bare Ground: range 20–55%, mean 42.7%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine sandy or silty clay loams

Vegetation Description:
Stands of *Encelia californica-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (18–40%, mean 27.1%). Shrubs occur in two different strata, with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (2–15%, mean 6.7%) at 0–1 m tall. Trees are infrequently present. Total vegetation cover is 25–43%, mean cover is 33.5%.

In this association, the shrub layer is characterized by *Encelia californica, Eriogonum cinereum,* and *Artemisia californica. Malosma laurina, Yucca whipplei,* and *Salvia leucophylla* are often present, while *Salvia mellifera* and *Rhus integrifolia* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and often includes *Brassica nigra* and *Bromus madritensis.*

Encelia californica-Malosma laurina-Salvia mellifera Shrubland Association

California Encelia-Laurel Sumac-Black Sage Shrubland Association
***Encelia californica* Shrubland Alliance**
California Encelia Shrubland Alliance

Mapping Code: 3221

Local Description

Summary:
This shrubland association occurs on gentle to very steep southeast- and southwest-facing slopes at low elevations between 5–457 m. It is characterized by a codominance of *Encelia californica, Salvia mellifera,* and *Malosma laurina* in the shrub layer. The herbaceous layer is diverse and dominated by nonnative grasses and herbs. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Eastern Urban, Dry Inland, Immediate Coast, Western Fog Zone, Upper Elevation Santa Monica Mountains, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 5–457 m, mean 248.8 m
Aspect: southeast and southwest
Slope: range 1–48 degrees, mean 29.3 degrees
Topography (micro; macro): undulating; lower to upper slope
Litter Cover: range 15–45%, mean 28.8%
Small Rock Cover: range 4–35%, mean 17.8%
Large Rock Cover: range 0–8%, mean 2.5%
Bare Ground: range 5–50%, mean 30%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Encelia californica-Malosma laurina-Salvia mellifera* Shrubland form an open to intermittent shrub layer (5–55%, mean 35.3%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–10 m tall. The herbaceous layer is open to intermittent (0–40%, mean 3.8%) at 0-1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.3%) with conifers at 0–10 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 29–60%, mean cover is 39.4%.

In this association, the shrub layer is characterized by *Encelia californica, Salvia mellifera*, *Malosma laurina,* and *Yucca whipplei. Artemisia californica* is often present, while *Eriogonum fasciculatum, Eriogonum cinereum,* and *Ceanothus megacarpus* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Leymus condensatus, Marah macrocarpus, Bromus madritensis*, *Pennisetum setaceum,* and *Medicago polymorpha*.

Comments:
This association is distinctive from others in the *Encelia californica* Alliance by having a codominance of three shrubs. One of them, *Malosma laurina,* is an evergreen broadleaf species that contrasts with the other two codominants by being typically both taller and broader. *Salvia mellifera* and *Encelia californica* may look similar from a distance, especially during the summer when their leaves are drier and may be mostly absent.

Encelia californica-Rhus integrifolia Shrubland Association

California Encelia-Lemonade Berry Shrubland Association
***Encelia californica* Shrubland Alliance**
California Encelia Shrubland Alliance

Mapping Code: 3226

Local Description

Summary:
This shrubland association occurs on somewhat steep to abrupt southeast-facing slopes at low elevations between 2–625 m. It is characterized by a codominance of *Encelia californica* and *Rhus integrifolia* in the shrub. The herbaceous layer is generally insignificant and composed of nonnative species. The emergent tree layer is usually not present.

Distribution:
This association is sampled in the Western Fog Zone, Immediate Coast, Dry Inland, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 2–625 m, mean 148.8 m
Aspect: southeast
Slope: range 15–75 degrees, mean 37.4 degrees
Topography (micro; macro): undulating; lower to upper slope
Litter Cover: range 5–15%, mean 10%
Small Rock Cover: range 10–50%, mean 26.3%
Large Rock Cover: range 0–8%, mean 3.3%
Bare Ground: range 5–60%, mean 29.6%
Parent Material: igneous
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Encelia californica-Rhus integrifolia* Shrubland form an open to intermittent shrub layer (10–51%, mean 32.7%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–11%, mean 2.2%) at 0-1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 12–51%, mean cover is 35%.

In this association, the shrub layer is characterized by *Encelia californica, Rhus integrifolia,* and *Eriogonum cinereum. Salvia mellifera* and *Yucca whipplei* are frequently included in this layer. The tree layer is emergent and open and may infrequently include *Schinus molle* and *Pinus* sp. at low cover. The herbaceous layer is simple and sometimes includes *Dichelostemma capitatum, Bromus madritensis, Nassella lepida, Avena fatua,* and *Pennisetum setaceum*.

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 15 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Pennisetum setaceum, Avena fatua, Bromus madritensis, Myoporum laetum, Erodium cicutarium, Brassica nigra, Bromus hordeaceus, Nicotiana glauca, Foeniculum vulgare, Bromus diandrus, Hirschfeldia incana, Schinus molle, Sonchus oleraceus

Samples Used in Description: (n = 15)
AA1007, AA1009, AA1010, rap0659, rap0661, rap0884, rap0932, rap1297, rap1465, rap1602, rap1821, rap1836, rap2113, rap2610, rap2804

Comments:
This association differs from the other *Encelia californica* associations by the codominance of the low sprawling evergreen shrub *Rhus integrifolia*. This may resemble the *E. californica-Salvia mellifera-Malosma laurina* Association in structure. It differs from that type by being typically restricted to low elevation and steep slopes, usually relatively close to the ocean. This is a common vegetation type on bluffs facing the immediate coast along Pacific Coast Highway.

Phases:
None

COMMON NAME	California Encelia-Lemonade Berry Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Encelia californica* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This association may also occur elsewhere close to the ocean in southern California (Sawyer and Keeler-Wolf 1995). Due to development along the coast, it is likely to be relatively rare with few high-quality examples remaining out of protected areas.

Sawyer and Keeler-Wolf 1995

Eriogonum cinereum Shrubland Association

Ashy Buckwheat Shrubland Association
***Eriogonum cinereum* Shrubland Alliance**
Ashy Buckwheat Shrubland Alliance

Mapping Code: 3257

Local Description

Summary:
This shrubland association occurs on moderate to abrupt southwest-facing slopes at low elevations between 0–500 m. It is characterized by a dominance of *Eriogonum cinereum* in the shrub layer. The herbaceous layer has no characteristic species. The emergent tree layer is generally absent but can include *Quercus agrifolia* and *Umbellularia californica.*

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Western Fog Zone, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 0–500 m, mean 289.5 m
Aspect: southwest
Slope: range 9–80 degrees, mean 35.6 degrees
Topography (micro; macro): undulating, flat, or convex; lower to upper slope
Litter Cover: range 10–35%, mean 16.7%
Small Rock Cover: range 3–46%, mean 23.1%
Large Rock Cover: range 0–85%, mean 17.1%
Bare Ground: range 0–65%, mean 27.8%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (3–37%, mean 18.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–33%, mean 10.7%) at 0–2 m tall. Trees are occasionally emergent (0–2% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 6–47%, mean cover is 29.2%.

In this association, the shrub layer is characterized by *Eriogonum cinereum. Artemisia californica* is usually present. *Yucca whipplei, Salvia mellifera, Malosma laurina,* and *Lotus scoparius* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Centaurea melitensis, Bromus madritensis, Leymus condensatus, Bromus diandrus,* and *Hirschfeldia incana.*

Comments:
This is an endemic alliance and association to the Ventura region of California and probably has most of its area represented within the SAMO study area. It is characteristic of steep usually southerly facing slopes below 600 m elevation and is often found on rocky or eroded cliffs. An early seral (postfire) phase has been identified with a higher cover of *Malacothamnus fasciculatus* and *Leymus condensatus*.

Phases:
Eriogonum cinereum (Ashy Buckwheat/Annual Grass-Herb) Phase [3257]
Eriogonum cinereum-Malacothamnus fasciculatus/Leymus condensatus (Ashy Buckwheat-Bush Mallow/Giant Wild Rye) Phase [3259]

Eriogonum fasciculatum Shrubland Association

California Buckwheat Shrubland Association
***Eriogonum fasciculatum* Shrubland Alliance**
California Buckwheat Shrubland Alliance

Mapping Code: 3241

Local Description

Summary:
This shrubland association occurs on gentle to very steep slopes of variable aspect at low elevations between 5–563 m. It is characterized by the dominance of *Eriogonum fasciculatum* in the shrub layer. The herbaceous layer is largely a sparse mix of nonnative species. The emergent tree layer is largely absent.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Eastern Urban Simi Hills Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 5–563 m, mean 389.5 m
Aspect: variable
Slope: range 2–55 degrees, mean 24.2 degrees
Topography (micro; macro): undulating, flat, or convex; lower slope to ridgetop
Litter Cover: range 10–40%, mean 21.7%
Small Rock Cover: range 10–65%, mean 33.4%
Large Rock Cover: range 0–48%, mean 4.7%
Bare Ground: range 8–70%, mean 32.2%
Parent Material: sedimentary or igneous
Soil Texture: coarse loamy sand to moderately fine clay loam

Vegetation Description:
Stands of *Eriogonum fasciculatum* Shrubland form an open to intermittent shrub layer (5–48%, mean 23.3%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–25%, mean 6%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.1%) with hardwoods at 0–2 m tall. Total vegetation cover is 6–49%, mean cover is 29.3%.

In this association, the shrub layer is characterized by *Eriogonum fasciculatum. Lotus scoparius*, *Artemisia californica, Malosma laurina,* and infrequently includes *Quercus agrifolia*. The herbaceous layer is diverse and sometimes includes *Bromus madritensis, Bromus diandrus*, *Brassica nigra,* and *Centaurea melitensis.*

Other Noteworthy Species:
Leptodactylon californicum was found in 1 of 31 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G5T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Stanleya pinnata was found in 1 of 31 surveys of this plant community. Regionally, the park considers this species as Locally Rare. This species is not listed by CNPs. Global rank is none, and state rank is none (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Bromus madritensis, Bromus diandrus, Brassica nigra, Centaurea melitensis, Avena, Hirschfeldia incana, Nicotiana glauca, Erodium cicutarium, Spartium junceum, Melilotus indicus, Piptatherum miliaceum, Erodium botrys, Avena fatua, Pennisetum setaceum, Foeniculum vulgare, Cistus, Ricinus communis, Medicago polymorpha, Rosmarinus officinalis, Acacia redolens, Avena barbata, Bromus hordeaceus, Cortaderia, Melilotus officinalis, Mesembryanthemum crystallinum

Samples Used in Description: (n = 31)
AA0233cc, AA0274cc, AA0653, AA0798, AA0969, AA1114, AA1126, rap0225m, rap0304, rap0357, rap0391, rap0731, rap0757, rap1275, rap1283, rap1447m, rap1457, rap1458, rap1849, rap1886, rap2131, rap2325, rap2359, rap2362, rap2407, rap2440, rap2469rlv, rap2476, rap2642rlv, rap2657, rap2864rlv

Comments:
This is a common disturbance-related association. It is often found on road cuts and other nonnatural clearings such as fuel breaks and abandoned house pads. It also may occur after fire in chaparral and some drier coastal scrubs. The most common postfire phase is the *Eriogonum fasciculatum-Lotus scoparius* phase.

Phases:
Eriogonum fasciculatum (California Buckwheat) Phase [3241]
Eriogonum fasciculatum-Lotus scoparius (California Buckwheat-Deerweed) Phase [3249]

COMMON NAME	California Buckwheat Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Eriogonum fasciculatum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This association is known from the Santa Monica Mountains as well as San Diego and western Riverside counties. It probably is widespread throughout much of central and south coastal California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
The *Eriogonum fasciculatum* Association usually occurs on alluvial/depositional, lower to upper slopes that are undulating or convex. Parent material is usually granitic or sedimentary. Many stands denote recent disturbance from invasive annual species, grazing, erosion, foot traffic, and so forth.

Vegetation Description:
In the *Eriogonum fasciculatum* Association, *E. fasciculatum* is consistently present at low to high cover. A wide variety of chaparral, coastal sage, and disturbance shrub species (e.g., *Artemisia californica*, *Lotus scoparius, Lessingia filaginifolia*, *Rhus ovata*, *Salvia apiana*, *Adenostoma fasciculatum*) may be present at low cover. Diverse annual herbs compose the herb understory, the most common being natives *Cryptantha* spp. and nonnatives such as *Hirschfeldia incana, Erodium* spp., *Bromus* spp., and *Avena* spp.

Comments:
The colonization abilities of *Eriogonum fasciculatum* are prodigious in southern California; however, they may be helped in some areas by artificial seeding programs along road cuts and so forth.

Eriogonum fasciculatum-Salvia mellifera-Malosma laurina Shrubland Association

California Buckwheat-Black Sage-Laurel Sumac Shrubland Association
***Eriogonum fasciculatum* Shrubland Alliance**
California Buckwheat Shrubland Alliance

Mapping Code: 3248

Local Description

Summary:
This shrubland association occurs on somewhat steep to very steep southwest- and southeast-facing slopes at low elevations between 0–681 m. It is characterized by a codominance of *Eriogonum fasciculatum, Salvia mellifera,* and *Malosma laurina* in the shrub layer. The herbaceous layer is generally insignificant and composed of scattered nonnative species. The emergent tree layer includes, on occasion, *Quercus agrifolia* and *Q. lobata*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Simi Hills Inland, Dry Inland, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 0–681 m, mean 408.9 m
Aspect: southwest and southeast
Slope: range 15–50 degrees, mean 31.3 degrees
Topography (micro; macro): undulating, convex, or flat; lower to upper slope
Litter Cover: range 2–40%, mean 24.6%
Small Rock Cover: range 2–50%, mean 23.2%
Large Rock Cover: range 0–50%, mean 5.9%
Bare Ground: range 10–80%, mean 36.4%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Eriogonum fasciculatum-Salvia mellifera-Malosma laurina* Shrubland form an open to intermittent shrub layer (11–48%, mean 31%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–25%, mean 3.8%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 15–50%, mean cover is 34.9%.

In this association, the shrub layer is characterized by *Eriogonum fasciculatum, Salvia mellifera, Malosma laurina,* and *Adenostoma fasciculatum. Yucca whipplei* and *Rhus ovata* are often included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Quercus lobata* at low cover. The herbaceous layer is diverse and sometimes includes *Centaurea melitensis. Bromus madritensis, Cuscuta californica, Brassica nigra,* and *Hirschfeldia incana* may be present.

Eriogonum fasciculatum-Salvia apiana Shrubland Alliance

California Buckwheat-White Sage Shrubland Alliance

Mapping Code: 3410

Local Description

Summary:
This shrubland alliance occurs on somewhat steep to very steep southeast- or southwest-facing slopes at low elevations between 202–262 m. It is codominated by *Salvia apiana* and *Eriogonum fasciculatum* in the shrub layer and has a variety of native and nonnative herbs, all at low cover in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia* in 80% of the sampled stands.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 202–262 m, mean 232.4 m
Aspect: southeast and southwest
Slope: range 15–50 degrees, mean 34 degrees
Topography (micro; macro): undulating; lower to middle slope
Litter Cover: 15%
Small Rock Cover: range 5–45%, mean 25%
Large Rock Cover: range 1–2%, mean 1.5%
Bare Ground: range 20–45%, mean 32.5%
Parent Material: sedimentary, quaternary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of this shrubland alliance form an open shrub layer (10–29%, mean 18.8%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (3–30%, mean 13%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 1%) with hardwoods at 0–10 m tall. Total vegetation cover is 23–45%, mean cover is 32.6%.

In this alliance, the shrub layer is characterized by *Salvia apiana* and *Eriogonum fasciculatum*. *Yucca whipplei* is also characteristic but at very low cover values. *Artemisia californica* is occasionally included in this layer as are *Malosma laurina, Brickellia californica, Eriogonum cinereum, Salvia leucophylla,* and *Adenostoma fasciculatum*. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and is characterized by low cover of *Avena* sp. Other herbs sometimes include *Centaurea melitensis, Brassica nigra, Hirschfeldia incana,* and *Dudleya pulverulenta*.

Other Noteworthy Species:
Erysimum insulare was found in 1 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and

state listing is none (SAMO 2004).

Nonnative Species:
Avena, Centaurea melitensis, Brassica nigra, Hirschfeldia incana, Silybum marianum, Bromus madritensis, Bromus diandrus

Samples Used in Description: (n = 5)
AA1135, rap2305, rap2432, rap2436, rap2910

Comments:
This alliance is characteristic of the inland portions of the Los Angeles Basin and San Diego County. It is less frequent in the Coastal Fog Zone of southern California; hence, it is a relative rarity locally. The local stands appear to be restricted to the inland side of the crest of the Santa Monica Mountains in relatively xeric settings.

Phases:
None

COMMON NAME	California Buckwheat-White Sage Shrubland Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic subdesert shrubland
ALLIANCE	*Eriogonum fasciculatum-Salvia apiana* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This alliance occurs within the portions of southern California and Baja California, Mexico, bounded by the San Bernardino Mountains to the north and the Peninsular Ranges to the east.

Nations:
United States, Mexico

States or Provinces:
CA, Baja California Norte

Environmental Description:
Stands of this shrubland alliance of southern California and Baja California occur on south-facing slopes from 500 to 1,500 m elevation. Mean annual precipitation ranges from 35 cm in the northern end of the range (Los Angeles Basin) to 20 cm in the southern (Baja California) portion.

The most favorable habitat is uplands with shallow soils and boulders. Stands intergrade with other chaparral alliances and with other "coastal sage scrub" vegetation types.

Vegetation Description:
This mid elevation variety of southern California sage scrub is characterized by codominance of *Salvia apiana* and *Eriogonum fasciculatum*, each attaining about 20% cover. Other components of this sclerophyllous evergreen alliance often include *Adenostoma fasciculatum, Yucca whipplei, Ceanothus leucodermis, Ceanothus greggii, Lotus scoparius*, and *Quercus berberidifolia*. Emergent individuals of *Quercus agrifolia* may be present. The herbaceous layer is variable and may be composed of graminoid species.

Comments:
This alliance is known to be very common in the western granitic foothills (subsection M262Bn) of western Riverside County (Klein and Evens 2005) and San Diego County (Evens and San 2005).

Hazardia squarrosa/Nassella pulchra-Hemizonia fasciculata Shrubland Association

Sawtooth Goldenbush/Purple Needlegrass-Clustered Tar Plant Shrubland Association
***Hazardia squarrosa* Shrubland Alliance**
Sawtooth Goldenbush Shrubland Alliance

Mapping Code: 3263

Local Description

Summary:
This shrubland association occurs on gentle to somewhat steep northeast-facing slopes at low elevations between 6–486 m. It is characterized by the dominance of *Hazardia squarrosa* in the shrub layer and *Nassella pulchra and Hemizonia fasciculata* in the herbaceous layer.

Distribution:
This association is sampled in the Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, Dry Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 6–486 m, mean 225 m
Aspect: northeast
Slope: range 5–25 degrees, mean 14.3 degrees
Topography (micro; macro): flat or undulating; lower to upper slope
Litter Cover: range 20–85%, mean 39.2%
Small Rock Cover: range 0–10%, mean 4%
Large Rock Cover: range 0–2%, mean 0.4%
Bare Ground: range 6–55%, mean 24.8%
Parent Material: sedimentary
Soil Texture: moderately fine to fine clay

Vegetation Description:
Stands of *Hazardia squarrosa/Nassella pulchra-Hemizonia fasciculata* Shrubland form an open to intermittent shrub layer (7–48%, mean 22.2%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–2 m tall. The herbaceous layer is open to intermittent 9–37%, mean 22.5%) at 0–1 m tall. Trees are not present. Total vegetation cover is 30–72%, mean cover is 44.4%.

In this association, the shrub layer is characterized by *Hazardia squarrosa* and *Salvia leucophylla. Artemisia californica* is frequently included in this layer. Other shrubs sometimes include *Baccharis pilularis, Eriogonum cinereum, Yucca whipplei,* and *Eriophyllum confertiflorum*. The tree layer is absent. The herbaceous layer is simple and is characterized by *Hemizonia fasciculata* with *Nassella pulchra* often present. Other herbs sometimes include *Centaurea melitensis, Sisyrinchium bellum, Brassica nigra,* and *Bromus madritensis.*

Other Noteworthy Species:
Calochortus catalinae was found in 2 of 11 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Dichondra occidentalis was found in 1 of 11 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G4?, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Brassica nigra, Bromus madritensis, Bromus hordeaceus, Erodium cicutarium, Avena, Anagallis arvensis, Lactuca serriola, Bromus diandrus, Hirschfeldia incana, Stellaria media, Avena fatua, Erodium, Melilotus indicus, Nicotiana glauca, Phalaris aquatica, Sonchus

Samples Used in Description: (n = 11)
AA0122cc, AA1164, rap0987, rap0994, rap2162, rap2196m, rap2309, rap2633, rap2634, rap2805, rap2872rlv

Comments:
This association is indicative of a transitional state between herb-dominated grassland where presumably *Nassella pulchra* and *Hemizonia fasciculata* were among the principal species and various shrublands in the *Artemisia californica* and *Salvia leucophylla* alliances. *Hazardia squarrosa* is a common, early seral species that does well following mechanical disturbance or fire. The stability of these stands is something that should be investigated. They tend to have a higher native herbaceous component than many other shrublands in the study area. In some cases, these stands may be transitioning into denser coastal scrub; however, the stands that are in heavy clay appear to be stable.

Hazardia squarrosa-Artemisia californica Shrubland Association

Sawtooth Goldenbush-California Sagebrush Shrubland Association
***Hazardia squarrosa* Shrubland Alliance**
Sawtooth Goldenbush Shrubland Alliance

Mapping Code: 3262

Local Description

Summary:
This shrubland association occurs on moderately steep to steep northwest- and northeast-facing slopes at low elevations between 30–542 m. It is characterized by a dominance of *Hazardia squarrosa* and a subdominance of *Artemisia californica* in the shrub layer. In the herbaceous layer, there is a mixture of several native and nonnative species, none of which are particularly characteristic. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Dry Inland, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 30–542 m, mean 335.5 m
Aspect: northwest and northeast
Slope: range 8–35 degrees, mean 23.2 degrees
Topography (micro; macro): flat, convex, or undulating; lower to upper slope
Litter Cover: range 10–65%, mean 28.8%
Small Rock Cover: range 0–35%, mean 10.6%
Large Rock Cover: range 0–4%, mean 0.4%
Bare Ground: range 3–79%, mean 44.5%
Parent Material: sedimentary
Soil Texture: fine clay

Vegetation Description:
Stands of *Hazardia squarrosa-Artemisia californica* Shrubland form an open to intermittent shrub layer (6–50%, mean 27.8%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to intermittent (1–42%, mean 13.8%) at 0–1 m tall. Trees are occasionally emergent (0–7% cover, mean 0.7%) with conifers at 0–1 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 23–60%, mean cover is 42.2%.

In this association, the shrub layer is characterized by *Hazardia squarrosa. Artemisia californica* and *Salvia leucophylla* are frequently included in this layer. Other shrubs sometimes include *Baccharis pilularis, Mimulus aurantiacus,* and *Eriogonum cinereum*. The tree layer is emergent and open and infrequently includes *Quercus lobata* and *Juglans californica* at low cover. The herbaceous layer is diverse and often includes *Leymus condensatus* and *Brassica nigra*. Other herbs sometimes include *Avena fatua, Hirschfeldia incana, Bromus diandrus, Centaurea melitensis,* and *Bromus hordeaceus.*

Comments:
In contrast with the previous association of the *Hazardia squarrosa* Alliance, this type does not usually contain high cover of native perennial bunch grasses. It tends to be "weedier" with a higher percentage of nonnative species and higher cover of other shrubs such as *Artemisia californica* and *Salvia leucophylla*. However, in some cases, *Artemisia* cover will be rather low,

and the stand will be dominated by only *Hazardia* and nonnative herbs. These characteristics suggest either a stronger transition toward longer-persisting shrublands of the *Artemisia californica* Alliance or a successional stage developing from a more heavily disturbed annual grassland. These two trends are reflected in the two phases mentioned below.

Phases:
Hazardia squarrosa/Annual Grass-Herb (Sawtooth Goldenbush/Annual Grass-Herb) Phase [3261]
Hazardia squarrosa-Artemisia californica/Leymus condensatus (Sawtooth Goldenbush–California Sagebrush/Giant Wild Rye) Phase [3262]

Heteromeles arbutifolia-Malosma laurina Shrubland Association

Toyon-Laurel Sumac Shrubland Association
***Heteromeles arbutifolia* Shrubland Alliance**
Toyon Shrubland Alliance

Mapping Code: 2138

Local Description

Summary:
This shrubland association occurs on somewhat steep to very steep northeast- and northwest-facing slopes at low elevations between 50–584 m. It is characterized by a dominance of *Heteromeles arbutifolia* with a subdominance of *Malosma laurina* and several other species of lower average cover in the shrub layer. The herbaceous layer is not well characterized. The emergent tree layer occasionally includes both *Quercus agrifolia* and *Juglans californica*.

Distribution:
This association is sampled in the Eastern Urban, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, Immediate Coast, Dry Inland, Western Fog Zone, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 50–584 m, mean 298.5 m
Aspect: northeast and northwest
Slope: range 15–55 degrees, mean 31.8 degrees
Topography (micro; macro): variable (all); lower to upper
Litter Cover: range 25–65%, mean 41.9%
Small Rock Cover: range 0–35%, mean 13.7%
Large Rock Cover: range 0–10%, mean 1.9%
Bare Ground: range 10–53%, mean 31%
Parent Material: sedimentary or igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Heteromeles arbutifolia-Malosma laurina* Shrubland form an open to intermittent shrub layer (14–63%, mean 42.2%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0.5–10 m tall. The herbaceous layer is open (0–26%, mean 4.7%) at 0–2 m tall. Trees are occasionally emergent (0–42% cover, mean 3.7%) with conifers at 0–20 m tall and hardwoods at 0–15 m tall. Total vegetation cover is 30–65%, mean cover is 50%.

In this association, the shrub layer is characterized by *Heteromeles arbutifolia* and *Malosma laurina. Rhus ovata, Ceanothus spinosus, Cercocarpus betuloides,* and *Sambucus mexicana* are often included in this layer. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Leymus condensatus, Marah macrocarpus,* and *Marrubium vulgare.*

Comments:
This is a heterogeneous, generally mesic chaparral association dominated by toyon (*Heteromeles arbutifolia*). Its heterogeneity is indicated by the distinguishing of five phases (see below). All of these phases tend to occur on northerly facing steep slopes and share a number of species. The differences between them appear to be mostly related to site history (largely time since last fire

and frequency of fires) and proximity to different adjacent alliances, which may contribute to the higher or lower cover of associated species. In many cases, these stands were seen on small fragments of open space in highly developed areas where fires are rare but human disturbance is high.

Phases:
Heteromeles arbutifolia (Toyon-Coast Live Oak) Phase [2137]
Heteromeles arbutifolia-Salvia mellifera (Toyon-Black Sage Sumac) Phase [2133]
Heteromeles arbutifolia-Cercocarpus betuloides (Toyon-Birch Leaf Mountain Mahogany) Phase [2136]
Heteromeles arbutifolia-Malosma laurina (Toyon-Laurel Sumac) Phase [2138]
Heteromeles arbutifolia-Artemisia californica-Mimulus aurantiacus (Toyon-California Sagebrush-Bush Monkey Flower) Phase [2135]

COMMON NAME	Toyon-Laurel Sumac Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Heteromeles arbutifolia* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. It is likely to occur throughout much of cismontane central and southern California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Two other associations of the *Heteromeles arbutifolia* Alliance have been described from western Riverside County (Klein and Evens 2005). They are the *Heteromeles arbutifolia-Artemisia*

californica Association, where *Artemisia californica* codominates with *Heteromeles arbutifolia* in the shrub overstory, and the *Heteromeles arbutifolia-Quercus berberidifolia-Cercocarpus betuloides-Fraxinus dipetala* Association, where *Quercus berberidifolia*, *Fraxinus dipetala*, and *Cercocarpus betuloides* are characteristically present as codominant or subdominant shrubs. Borchert et al. 2004 describe a *Heteromeles arbutifolia-Prunus ilicifolia* Alliance from the Los Padres National Forest of southern and central coastal California. It has similarities with this association but has much higher average cover of *Prunus ilicifolia*.

References:
Borchert et al. 2004, Klein and Evens 2005

Lepidospartum squamatum Shrubland Alliance

Scale Broom Shrubland Alliance

Mapping Code: 2220

Local Description

Summary:
One example of this shrubland alliance occurs on a gentle slope at 311 m elevation. It is dominated by *Lepidospartum squamatum* in the shrub layer and has a variety of native and nonnative species at low cover in the herbaceous layer. The emergent tree layer includes *Platanus racemosa*.

Distribution:
This alliance is sampled in the Simi Hills Inland region of the study area.

Environmental Description:
Elevation: 311 m
Aspect: flat
Slope: 2 degrees
Topography (micro; macro): flat; bottom slope
Litter Cover: no data
Small Rock Cover: 30%
Large Rock Cover: 10%
Bare Ground: 40%
Parent Material: sedimentary
Soil Texture: coarse loamy sand

Vegetation Description:
One stand of this shrubland alliance forms an open shrub layer (18%). Shrubs occur in two different strata with low shrubs at 0–0.5 m tall and tall shrubs at 0.5–1 m tall. The herbaceous layer is open (5%) at 0.1–0.5 m tall. Trees are occasionally emergent (< 1%) with hardwoods at 1–10 m tall. Total vegetation cover is 23%.

In this alliance, the shrub layer is characterized by *Lepidospartum squamatum*. *Eriogonum fasciculatum* and *Baccharis salicifolia* are also included in this layer. The tree layer is emergent and open and includes *Platanus racemosa* at low cover. The herbaceous layer is simple, and the nonnative *Hirschfeldia incana* is the most abundant. Other herbs include *Centaurea melitensis* and *Artemisia douglasiana*.

Other Noteworthy Species:
None

Nonnative Species:
Hirschfeldia incana, Centaurea melitensis

Samples Used in Description: (n = 1)
rap2680

Comments: This alliance is represented in the study area only in a few alluvial settings. It is more common inland from the study area in the Los Angeles Basin and other south coastal drainages.

Phases:
None

COMMON NAME	Scale Broom Alliance
SYNONYM	Riverdisian Alluvial Fan Sage Scrub (in part) Holland (1986)
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.2. Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.2.N. Natural/Seminatural
FORMATION	III.A.4.N.b. Intermittently flooded microphyllous shrubland
ALLIANCE	*Lepidospartum squamatum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	The alliance is considered a G4S4, but several associations are ranked as Rare.

Global Description

Distribution:
The alliance ranges from central coastal California (western Stanislaus County) south through the California coast ranges and the far southern Sierra Nevada foothills to the western Mojave Desert and south to coastal Baja California, Mexico.

Nations:
United States, Mexico

States or Provinces:
CA, Baja California Norte

Environmental Description:
This shrubland alliance of the arid southwest is found on rarely flooded, low-gradient deposits along streams. Substrates are usually rocky with little soil. Elevations range from sea level to 1,800 m. Annual precipitation is quite variable and episodic but rarely exceeds 30 cm. Summer temperatures are very hot, and some areas in the Mojave may exceed 30 degrees Celsius for many days in the summer.

Vegetation Description:
Stands of this desert streamside shrubland contain *Lepidospartum squamatum* as a dominant or important species in the shrub layer. Other shrubs present may include *Rhus trilobata, Artemisia tridentata, Artemisia californica, Acacia greggii, Cercocarpus montanus* var. *glaber, Isomeris arboreus, Encelia farinosa, Eriogonum fasciculatum, Hymenoclea salsola, Yucca whipplei, Lotus scoparius, Eriodictyon crassifolium, Baccharis salicifolia, Toxicodendron diversilobum, Opuntia* spp., and *Rhus ovata*. Emergent individuals of *Juniperus californica, Platanus racemosa, Juglans californica* var. *californica, Populus fremontii, Malosma laurina, Rhus integrifolia,* and *Sambucus mexicana* may be present. Two rare forbs, *Dodecahema leptocerus* and *Eriastrum densifolium* subsp. *sanctorum,* are often associated with stands of this alliance in the eastern Los Angeles Basin.

Comments:
Cycles of drought and flood shape this alliance. Periodic disturbances such as floods and fires remove shrubs and trees. If stands are not disturbed for a long period of time, emergent trees gradually take over this shrubland. This alliance is much reduced in extent in the southern portion of its range by flood control projects and other development.

Lotus scoparius Shrubland Association

Deerweed Shrubland Association
***Lotus scoparius* Shrubland Alliance**
Deerweed Shrubland Alliance

Mapping Code: 3270

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 24–539 m. It is characterized by the dominance of *Lotus scoparius* in the shrub layer and a variety of mostly nonnative herbs, none particularly characteristic, in the herbaceous layer. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, Dry Inland, Immediate Coast, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 24–539 m, mean 336.8 m
Aspect: variable
Slope: range 2–38 degrees, mean 24.5 degrees
Topography (micro; macro): undulating, convex, or flat; middle to upper slope
Litter Cover: range 20–65%, mean 37%
Small Rock Cover: range 1–60%, mean 23.6%
Large Rock Cover: range 0–25%, mean 3.8%
Bare Ground: range 5–60%, mean 28.4%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Lotus scoparius* Shrubland form an open to intermittent shrub layer (4–50%, mean 26.7%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to intermittent (0–42%, mean 8.4%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.2%) with hardwoods at 0–5 m tall. Total vegetation cover is 13–68%, mean cover is 35.2%.

In this association, the shrub layer is characterized by *Lotus scoparius. Salvia mellifera*, *Eriogonum fasciculatum, Artemisia californica, Malosma laurina,* and *Adenostoma fasciculatum* are often included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and may include *Centaurea melitensis, Hirschfeldia incana, Brassica nigra,* and *Bromus madritensis.*

Comments:
This is one of the classic seral shrub associations throughout much of central and southern California. It is characteristic of postfire chaparral and coastal sage scrub. There seems to be no

strong reason to further subdivide this association based on short-term differences in subdominant species. The main characteristic of this association is that it reflects a short-term, postfire condition. It has a variety of weakly distinguishable phases that reflects the original prefire vegetation. In general, the phases reflect either a chaparral (e.g., *Adenostoma fasciculatum*) prefire setting or a coastal sage (e.g., *Artemisia californica*) prefire setting.

Phases:
Lotus scoparius-Artemisia californica/Annual Grass-Herb (Deerweed-California Sagebrush/Annual Grass-Herb) Phase [3273]
Lotus scoparius-Malacothamnus fasciculatus-Adenostoma fasciculatum-Salvia mellifera (Deerweed-Bush Mallow-Chamise-Black Sage) Phase [3272]

Malacothamnus fasciculatus Shrubland Association

Bush Mallow Shrubland Association
***Malacothamnus fasciculatus* Shrubland Alliance**
Bush Mallow Shrubland Alliance

Mapping Code: 3287

Local Description

Summary:
This shrubland association occurs on gentle to steep southwest- and southeast-facing slopes at low elevations between 0–483 m. It is characterized by a strong dominance of *Malacothamnus fasciculatus* in the shrub layer. The herbaceous layer is generally insignificant and composed of mostly fire-following natives or widespread nonnative weedy species. The emergent tree layer is generally absent but may include *Quercus agrifolia, Juglans californica,* and *Platanus racemosa*.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 0–483 m, mean 304 m
Aspect: southwest and southeast
Slope: range 2–35 degrees, mean 23.5 degrees
Topography (micro; macro): variable (all); bottom to ridgetop
Litter Cover: range 20–50%, mean 35%
Small Rock Cover: range 10–45%, mean 21.4%
Large Rock Cover: range 0–1%, mean 0.6%
Bare Ground: range 14–60%, mean 32.7%
Parent Material: sedimentary and igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Malacothamnus fasciculatus* Shrubland form an open to intermittent shrub layer (12–54%, mean 34.8%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–22%, mean 5.3%) at 0–1 m tall. Trees are occasionally emergent (0–5% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 26–55%, mean cover is 40.4%.

In this association, the shrub layer is characterized by *Malacothamnus fasciculatus*, with *Salvia mellifera* often present. *Artemisia californica, Malosma laurina, Encelia californica,* and *Ceanothus megacarpus* are sometimes included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia, Juglans californica,* and *Platanus racemosa* at low cover. The herbaceous layer is simple and may include *Centaurea melitensis, Brassica nigra, Bromus diandrus, Hirschfeldia incana,* and *Hemizonia fasciculata.*

Comments:
This is the first project in which this alliance has been defined. It is a seral, postfire alliance distinguished by the dominance or codominance of the short-lived tall shrub *Malacothamnus fasciculatus.* The diversity of associations defined in the SAMO study area is indicative of the diversity of recent postfire settings in chaparral and coastal sage scrub in these mountains. This association is the most pure expression of the alliance. In this association, the variety of associated shrub species is almost equally derived from chaparral and coastal sage scrub vegetation (though none are strongly represented at high frequency or cover). Thus, this association may be the result of fire having burned through a stand of chaparral or coastal sage scrub without a large component of resprouting shrubs or where the obligate seeding species other than *M. fasciculatus* had less than favorable postfire germination.

Malacothamnus fasciculatus-Ceanothus megacarpus Shrubland Association

Bush Mallow-Big Pod Ceanothus Shrubland Association
***Malacothamnus fasciculatus* Shrubland Alliance**
Bush Mallow Shrubland Alliance

Mapping Code: 3288

Local Description

Summary:
This shrubland association occurs on moderate to very steep slopes of variable aspect at low elevations between 139–467 m. It is characterized by a codominance of *Malacothamnus fasciculatus* and *Ceanothus megacarpus* in the shrub layer. The simple herbaceous layer is not distinctive. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, Immediate Coast, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 139–467 m, mean 309.9 m
Aspect: variable
Slope: range 12–48 degrees, mean 28.3 degrees
Topography (micro; macro): variable (all); bottom to middle slope
Litter Cover: range 15–50%, mean 32.5%
Small Rock Cover: range 10–20%, mean 13.3%
Large Rock Cover: range 0–3%, mean 1%
Bare Ground: range 40–57%, mean 49%
Parent Material: igneous
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Malacothamnus fasciculatus-Ceanothus megacarpus* Shrubland form an open to intermittent shrub layer (30–57%, mean 45.2%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–20%, mean 4%) at 0–1 m tall. Trees are not present. Total vegetation cover is 38–57%, mean cover is 49.2%.

In this association, the shrub layer is characterized by *Ceanothus megacarpus, Malacothamnus fasciculatus, Malosma laurina,* and *Salvia mellifera. Adenostoma fasciculatum* and *Cercocarpus betuloides* are often included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Centaurea melitensis, Brassica nigra, Bromus diandrus,* and *Bromus madritensis*.

Comments:
In keeping with the discussion under the local comments of the *Malacothamnus fasciculatus* Association of this alliance (above), this particular association is reflective of the recent postfire settings where *Ceanothus megacarpus* is the principal reseeding native shrub. Most

Malacothamnus fasciculatus individuals in these stands will be crowded out and shade suppressed by the longer-lived and more broadly spreading *C. megacarpus* within a decade of the fire event.

The general decision was made in the classification of this alliance to include codominant shrub species of either the respective chaparral or coastal sage scrub analog alliances (e.g., *Ceanothus megacarpus, C. spinosus, Malosma laurina*, or *Salvia leucophylla*) within the seral *Malacothamnus fasciculatus* Alliance. This was because these situations are all typically short-lived and reflective first of the postfire condition and then of the overall environmental conditions (temperature, moisture, and perhaps soil fertility).

Phases:
None

Malacothamnus fasciculatus-Ceanothus spinosus Shrubland Association

Bush Mallow-Greenbark Ceanothus Shrubland Association
***Malacothamnus fasciculatus* Shrubland Alliance**
Bush Mallow Shrubland Alliance

Mapping Code: 3289

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 179–648 m. It is characterized by codominance of *Malacothamnus fasciculatus* and *Ceanothus spinosus* in the shrub layer. The simple herbaceous layer is not distinctive. The emergent tree layer includes occasional *Quercus agrifolia*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 179–648 m, mean 434.5 m
Aspect: variable
Slope: range 2–35 degrees, mean 20.6 degrees
Topography (micro; macro): concave or undulating; bottom to upper slope
Litter Cover: range 45–60%, mean 52.5%
Small Rock Cover: range 15–50%, mean 27%
Large Rock Cover: range 2–15%, mean 7%
Bare Ground: range 10–35%, mean 21.7%
Parent Material: sedimentary
Soil Texture: no data

Vegetation Description:
Stands of *Malacothamnus fasciculatus-Ceanothus spinosus* Shrubland form an open to intermittent shrub layer (38–60%, mean 49.2%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–2%, mean 0.5%) at 0–1 m tall. Trees are occasionally emergent (0–6% cover, mean 0.9%) with hardwoods at 0–10 m tall. Total vegetation cover is 41–60%, mean cover is 50.2%.

In this association, the shrub layer is characterized by *Ceanothus spinosus* and *Malacothamnus fasciculatus. Malosma laurina, Heteromeles arbutifolia, Adenostoma fasciculatum,* and *Cercocarpus betuloides* are often included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Umbellularia californica* at low cover. The herbaceous layer is simple, and *Leymus condensatus, Marah macrocarpus,* and *Bromus madritensis* are sometimes present.

FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Malacothamnus fasciculatus* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Since *Ceanothus spinosus* is a facultative resprouter (i.e., it both resprouts and germinates from seed following fires, per Borchert et al. 2004), it would be expected to overtop and shade out *M. fasciculatus* relatively rapidly following fire events. Thus, this association is likely to be even shorter lived than other associations in this alliance.

Borchert et al. 2004

Malacothamnus fasciculatus-Malosma laurina Shrubland Association

Bush Mallow-Laurel Sumac Shrubland Association
***Malacothamnus fasciculatus* Shrubland Alliance**
Bush Mallow Shrubland Alliance

Mapping Code: 3286

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 18–366 m. It is characterized by a codominance of *Malacothamnus fasciculatus* and *Malosma laurina* in the shrub layer. The herbaceous layer often has low cover of *Leymus condensatus.* The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Immediate Coast, Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 18–366 m, mean 153.3 m
Aspect: variable
Slope: range 2–40 degrees, mean 16.2 degrees
Topography (micro; macro): variable (all); bottom to middle slope
Litter Cover: range 40–80%, mean 62%
Small Rock Cover: range 0–30%, mean 10.7%
Large Rock Cover: range 0–5%, mean 0.8%
Bare Ground: range 0–35%, mean 16.8%
Parent Material: sedimentary
Soil Texture: moderately fine to fine clay loam

Vegetation Description:
Stands of *Malacothamnus fasciculatus-Malosma laurina* Shrubland form an open to intermittent shrub layer (28–59%, mean 42.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–22%, mean 5.5%) at 0–1 m tall. Trees are occasionally emergent (0–4% cover, mean 0.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 30–65%, mean cover is 47.7%.

In this association, the shrub layer is characterized by *Malacothamnus fasciculatus* and *Malosma laurina. Salvia leucophylla* and *Artemisia californica* are usually included in this layer. Other shrubs sometimes include *Encelia californica, Baccharis pilularis, Salvia mellifera, Hazardia squarrosa,* and *Eriogonum cinereum*. The tree layer is emergent and open and sometimes includes *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is simple and often includes *Leymus condensatus.* Other herbs may include *Bromus madritensis, Brassica nigra, Nassella lepida,* and *Marah macrocarpus.*

Comments:
This association of the *M. fasciculatus* Alliance is usually found in lower elevation settings where prefire conditions were likely to support stands of *Artemisia californica, Salvia leucophylla,* or

Malosma laurina Alliance stands. The general vegetation environment of this association can be considered coastal sage scrub, rather than chaparral. Occasional *Ceanothus spinosus* within these stands suggests that at least some stands are mesic, but most are probably relatively dry sites within the zone of summer fog. See comments on the related *M. fasciculatus-Salvia leucophylla* Association for the similarities between these two associations.

Malacothamnus fasciculatus-Salvia leucophylla Shrubland Association

Bush Mallow-Purple Sage Shrubland Association
***Malacothamnus fasciculatus* Shrubland Alliance**
Bush Mallow Shrubland Alliance

Mapping Code: 3281

Local Description

Summary:
This shrubland association occurs on moderate to steep northwest facing slopes at low elevations between 5–576 m. It is characterized by a dominance of *Malosma fasciculatum* and a subdominance of *Salvia leucophylla* in the shrub layer and *Leymus condensatus* in the herbaceous layer. The emergent tree layer infrequently includes *Quercus agrifolia* and *Juglans californica*.

Distribution:
This association is sampled in the Dry Inland, Immediate Coast, Upper Elevation Santa Monica Mountains, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 5–576 m, mean 337.7 m
Aspect: northwest
Slope: range 2–45 degrees, mean 26.2 degrees
Topography (micro; macro): flat, convex, or undulating; lower slope to ridgetop
Litter Cover: range 15–65%, mean 33.8%
Small Rock Cover: range 10–50%, mean 24%
Large Rock Cover: range 0–2%, mean 0.4%
Bare Ground: range 2–55%, mean 29%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Malacothamnus fasciculatus-Salvia leucophylla* Shrubland form an open to intermittent shrub layer (18–58%, mean 39.7%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to intermittent (0–36%, mean 5.7%) at 0–2 m tall. Trees are occasionally emergent (0–5% cover, mean 0.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 32–60%, mean cover is 46%.

In this association, the shrub layer is characterized by *Malacothamnus fasciculatus, Salvia leucophylla,* and *Artemisia californica*. *Malosma laurina, Rhus ovata, Lotus scoparius,* and *Encelia californica* are sometimes included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Leymus condensatus, Centaurea melitensis,* and *Bromus madritensis.*

Comments:
This association of the *Malacothamnus fasciculatus* Alliance can be considered another seral stage in the general vegetation realm of the coastal sage scrub. In this association the major associate of the bush mallow is *Salvia leucophylla*. Although both *Malosma laurina* and *Artemisia californica* are present in more than half the stands, their cover is substantially lower than their average cover in the *M. fasciculatus-Malosma laurina* Association. Conversely, *Salvia leucophylla* is in higher cover than in that association. However, in many ways this association

and the previous *M. fasciculatus-Malosma laurina* Association are very similar and their distinction at the association level is somewhat questionable. There may be a rationale, with further analysis, to consider both as phases of a larger, more broadly encompassing association.

Malacothamnus fasciculatus-Salvia mellifera Shrubland Association

Bush Mallow-Black Sage Shrubland Association
***Malacothamnus fasciculatus* Shrubland Alliance**
Bush Mallow Shrubland Alliance

Mapping Code: 3282

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 152–477 m. It is characterized by a codominance of *Malacothamnus fasciculatus* and *Salvia mellifera* in the shrub layer. The herbaceous layer is indistinct. The emergent tree layer includes occasional *Juglans californica* and *Quercus agrifolia*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Dry Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 152–477 m, mean 318 m
Aspect: variable
Slope: range 2–35 degrees, mean 23.5 degrees
Topography (micro; macro): undulating or concave; bottom to upper slope
Litter Cover: range 30–45%, mean 33.8%
Small Rock Cover: range 5–45%, mean 20%
Large Rock Cover: range 0–5%, mean 1.7%
Bare Ground: range 15–50%, mean 33.3%
Parent Material: igneous or sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Malacothamnus fasciculatus-Salvia mellifera* Shrubland form an open to intermittent shrub layer (24–50%, mean 35.1%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–17%, mean 4.1%) at 0–1 m tall. Trees are occasionally emergent (0–7% cover, mean 1.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 27–55%, mean cover is 40.3%.

In this association, the shrub layer is characterized by *Salvia mellifera* and *Malacothamnus fasciculatus. Malosma laurina, Artemisia californica, Yucca whipplei,* and *Adenostoma fasciculatum* are usually included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Centaurea melitensis, Brassica nigra, Bromus madritensis,* and *Bromus diandrus.*

Other Noteworthy Species:
Delphinium parryi was found in 1 of 12 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 3-2-3. Global rank is G4T2, and state rank is S2.2 (CNPS 2005). Federal listing is Species of Concern, and state listing is none (SAMO 2004).

Juglans californica was found in 3 of 12 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Brassica nigra, Bromus madritensis, Bromus diandrus, Avena fatua, Marrubium vulgare, Anagallis arvensis, Erodium, Erodium cicutarium, Medicago polymorpha, Melilotus indicus

Samples Used in Description: (n = 12)

Comments:
This association of the *Malacothamnus fasciculatus* Alliance bridges the gap between chaparral and coastal sage scrub based on the derivation of its prefire species pool. There is a fairly even mix of typical coastal sage species (*Encelia californica, Artemisia californica*) and chaparral species (*Adenostoma fasciculatum, Ceanothus megacarpus*) along with species such as *Salvia mellifera, Eriogonum fasciculatum,* and *Malosma laurina*, which may be found in either.

Phases:
None

COMMON NAME	Bush Mallow-Black Sage Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Malacothamnus fasciculatus* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Malosma laurina Shrubland Association

Laurel Sumac Shrubland Association
***Malosma laurina* Shrubland Alliance**
Laurel Sumac Shrubland Alliance

Mapping Code: 7142

Local Description

Summary:
This shrubland association occurs on gentle to very steep southeast- to northwest-facing slopes at low elevations between 0–528 m. It is characterized by a dominance of *Malosma laurina* in the shrub layer and a relatively nondescript herbaceous layer. The emergent tree layer includes *Quercus agrifolia* in about 20% of the stands.

Distribution:
This association is sampled in the Eastern Urban, Immediate Coast, Simi Hills Inland, Western Fog Zone, Upper Elevation Santa Monica Mountains, Dry Inland, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 0–528 m, mean 235.7 m
Aspect: southeast to northwest
Slope: range 2–65 degrees, mean 23.4 degrees
Topography (micro; macro): variable (all); bottom to ridgetop
Litter Cover: range 25–85%, mean 57.5%
Small Rock Cover: range 0–50%, mean 16.4%
Large Rock Cover: range 0–60%, mean 4.5%
Bare Ground: range 0–60%, mean 19.8%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Malosma laurina* Shrubland form an open to intermittent shrub layer (7–64%, mean 31.7%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–10 m tall. The herbaceous layer is open to intermittent (0–-45%, mean 10%) at 0–1 m tall. Trees are occasionally emergent (0–17% cover, mean 1.4%) with conifers at 0–10 m tall and hardwoods at 0–15 m tall. Total vegetation cover is 21–68%, mean cover is 42.8%.

In this association, the shrub layer is characterized by *Malosma laurina. Artemisia californica, Eriogonum fasciculatum, Salvia mellifera, Heteromeles arbutifolia,* and *Ceanothus megacarpus* are sometimes included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia, Juglans californica, Platanus racemosa,* and *Schinus molle* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Leymus condensatus*, *Bromus diandrus, Centaurea melitensis,* and *Hirschfeldia incana*.

Comments:
The Santa Monica Mountains hold the dubious distinction of being the center for diversity of the *Malosma laurina* Alliance in the known world—dubious because of the apparent fact that *M. laurina* has increased its presence throughout its range in the historic past (Taylor 2004 and Stephen Davis personal communication 2003). The dominant species in this alliance resprouts prodigiously from the base following fire and with higher fire frequencies may tend to dominate stands that were once composed of a higher diversity of shrub species. This is the basic association of this locally diverse alliance where *M. laurina* is by far the most dominant species with little else to distinguish it. Two phases have been defined—a phase with a relatively dense overstory of *M. laurina* and a more open phase with scattered annual grasses and herbs in the understory.

Phases:
Malosma laurina (Laurel Sumac) Phase [7142]
Malosma laurina/Annual Grass-Herb (Laurel Sumac/Annual Grass-Herb) Phase [2145]

COMMON NAME	Laurel Sumac Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Malosma laurina* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. The alliance is known from San Diego County and from western Riverside County as well (Evens and San 2005 and Klein and Evens 2005).

Nations:
United States

States or Provinces:
CA

Malosma laurina-Artemisia californica Shrubland Association

Laurel Sumac-California Sagebrush Shrubland Association
***Malosma laurina* Shrubland Alliance**
Laurel Sumac Shrubland Alliance

Mapping Code: 7148

Local Description

Summary:
This shrubland association occurs on gentle to steep northeast- and northwest-facing slopes at low elevations between 2–611 m. It is characterized by a dominance of *Malosma laurina* and a subdominance of *Artemisia californica;* in many cases, *Salvia leucophylla* in the shrub layer; and typically a minor presence of the grass *Leymus condensatus* in the herbaceous layer. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Immediate Coast, Western Fog Zone, Simi Hills Inland, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, Dry Inland, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 2–611 m, mean 227.6 m
Aspect: northeast and northwest
Slope: range 2–40 degrees, mean 25.4 degrees
Topography (micro; macro): undulating, convex, or flat; lower to upper slope
Litter Cover: range 50–50%, mean 50%
Small Rock Cover: range 0–35%, mean 10.1%
Large Rock Cover: range 0–4%, mean 0.5%
Bare Ground: range 5–55%, mean 27.1%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam to fine clay

Vegetation Description:
Stands of *Malosma laurina-Artemisia californica* Shrubland form an open to intermittent shrub layer (10–63%, mean 40.2%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0–36%, mean 5.9%) at 0–2 m tall. Trees are occasionally emergent (0–11% cover, mean 0.8%) with hardwoods at 0–10 m tall. Total vegetation cover is 26–65%, mean cover is 46.8%.

In this association, the shrub layer is characterized by *Malosma laurina* and *Artemisia californica*. *Salvia leucophylla* is often present. *Malacothamnus fasciculatus, Eriogonum cinereum, Mimulus aurantiacus, Salvia mellifera, Baccharis pilularis,* and *Sambucus mexicana* are sometimes included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and often includes *Leymus condensatus.* Other herbs may include *Nassella lepida, Centaurea melitensis, Brassica nigra,* and *Marah macrocarpus.*

Other Noteworthy Species:
Baccharis plummerae was found in 1 of 48 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-1-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Calochortus catalinae was found in 1 of 48 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 9 of 48 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Brassica nigra, Hirschfeldia incana, Bromus madritensis, Phalaris aquatica, Euphorbia terracina, Nicotiana glauca, Bromus hordeaceus, Erodium, Acacia redolens, Melilotus indicus, Myoporum laetum, Senecio mikanioides, Anagallis arvensis, Avena barbata, Avena fatua, Bromus diandrus, Erodium cicutarium, Eucalyptus, Foeniculum vulgare, Marrubium vulgare

Samples Used in Description: (n = 48)
AA0273cc, AA0437, AA0570, AA0700, AA0722, AA0763, AA0767, AA0793, AA0797, AA0800, AA0849, AA0882, AA0935, AA1004, AA1150, AA1151, rap0025m, rap0059, rap0067, rap0074, rap0088, rap0214, rap0656m, rap0683, rap0685, rap0989, rap0995m, rap0997, rap1007, rap1066, rap1089m, rap1091, rap1194, rap1245m, rap1416, rap1417, rap1453, rap1503, rap1538, rap1617, rap1766m, rap2037, rap2069, rap2302, rap2477, rap2732, rap2741, rap2763

Comments:
This association of the *Malosma laurina* Alliance is distinguished by the subdominance of the coastal sage scrub species, especially *Artemisia californica* and often *S. leucophylla*. The current model of how this association has arisen as a common type is that higher than historic fire frequencies and perhaps other disturbance, such as brush clearing, has afforded the resprouter

Malosma laurina the opportunity to dominate over what otherwise may have previously been stands historically dominated by *Artemisia californica* and/or *Salvia leucophylla*. Two phases of this association have been identified based on either the singular presence of *Artemisia californica* or a mixture of it and *Salvia leucophylla* associated with the dominant species.

Phases:
Malosma laurina-Artemisia californica (Laurel Sumac-California Sagebrush) Phase [7148]
Malosma laurina-Artemisia californica-Salvia leucophylla (Laurel Sumac-California Sagebrush-Purple Sage) Phase [2142]

COMMON NAME	Laurel Sumac-California Sagebrush Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Malosma laurina* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is likely present in low elevation slopes of southern California from the peninsular to transverse ranges from San Diego County north to Ventura County.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This association is similarly described in western Riverside and San Diego counties. However, it is within the *Artemisia californica* Alliance as the *Artemisia californica-Malosma laurina* Association where *Malosma laurina* is consistently present as a codominant or subdominant shrub. Shrubs *Salvia apiana, Mimulus aurantiacus,* and *Eriogonum fasciculatum* are often present at low cover.

Evens and San 2005, Klein and Evens 2005

Malosma laurina-Eriogonum cinereum Shrubland Association

Laurel Sumac-Ashy Buckwheat Shrubland Association
***Malosma laurina* Shrubland Alliance**
Laurel Sumac Shrubland Alliance

Mapping Code: 2141

Local Description

Summary:
This shrubland association occurs on gentle to abrupt southwest- and southeast-facing slopes at low elevations between 0–550 m. It is characterized by a dominance of *Malosma laurina* and a subdominance of *Eriogonum cinereum* in the shrub layer. The herbaceous layer is relatively insignificant with no apparent indicator species. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Immediate Coast, Western Fog Zone, Upper Elevation Santa Monica Mountains, Eastern Urban, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 0–550 m, mean 153.3 m
Aspect: southwest and southeast
Slope: range 2–70 degrees, mean 31.7 degrees
Topography (micro; macro): variable (all); bottom to ridgetop
Litter Cover: range 8–75%, mean 32.6%
Small Rock Cover: range 0–60%, mean 26%
Large Rock Cover: range 0–70%, mean 6.7%
Bare Ground: range 0–75%, mean 24.7%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Malosma laurina-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (10–52%, mean 33.7%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0–34%, mean 4.1%) at 0–2 m tall. Trees are occasionally emergent (0–5% cover, mean 0.2%) with hardwoods at 0–10 m tall. Total vegetation cover is 10–58%, mean cover is 37.9%.

In this association, the shrub layer is characterized by *Malosma laurina, Eriogonum cinereum,* and *Salvia mellifera. Artemisia californica, Yucca whipplei,* and *Encelia californica* are frequently included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is diverse and may include *Leymus condensatus, Brassica nigra, Bromus madritensis,* and *Nassella lepida.*

Comments:
This is a common and likely largely endemic association to the study area. It is common on steep southerly facing slopes, mostly close to the coast. The variety of associated species can be seen by scanning the list of minor phases that have been identified in the area. In general, variation is increased by seral stage (mostly time since fire influencing the presence of such species as *Lotus scoparius* and *Malacothamnus fasciculatus*) and local site conditions (slightly hotter and better drained slopes may have more *Salvia mellifera* while more coastal foggy slopes may have more *Rhus integrifolia* and *Artemisia californica*). However, the degree of overlap between these phases in species cover and composition was too great to warrant further separation into distinct associations.

Phases:
Malosma laurina-Eriogonum cinereum (Laurel Sumac-Ashy Buckwheat) Phase [2141]
Malosma laurina-Rhus integrifolia-Eriogonum cinereum-Artemisia californica (Laurel Sumac-Lemonade Berry-Ashy Buckwheat-California Sagebrush) Phase [21413]
Malosma laurina-Malacothamnus fasciculatus-Eriogonum cinereum-Salvia mellifera (Laurel Sumac-Bush Mallow-Ashy Buckwheat-Black Sage) Phase [7146]
Malosma laurina-Eriogonum cinereum-Lotus scoparius (Laurel Sumac-Ashy Buckwheat-Deerweed) Phase [7144]
Malosma laurina-Eriogonum cinereum-Salvia mellifera (Laurel Sumac-Ashy Buckwheat-Black Sage) Phase [7141]

Malosma laurina-Eriogonum fasciculatum Shrubland Association

Laurel Sumac-California Buckwheat Shrubland Association
***Malosma laurina* Shrubland Alliance**
Laurel Sumac Shrubland Alliance

Mapping Code: 21423

Local Description

Summary:
This shrubland association occurs on somewhat steep to abrupt southwest- and southeast-facing slopes at low elevations between 0–602 m. It is characterized by a codominance of *Malosma laurina* and *Eriogonum fasciculatum* in the shrub layer. The herbaceous layer is insignificant. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, Immediate Coast, Dry Inland, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 0–602, mean 413.7 m
Aspect: southwest and southeast
Slope: range 15–75 degrees, mean 35.1 degrees
Topography (micro; macro): variable (all); middle to upper slope
Litter Cover: range 2–35%, mean 16.8%
Small Rock Cover: range 2–65%, mean 29.7%
Large Rock Cover: range 0–85%, mean 7.6%
Bare Ground: range 2–45%, mean 21.2%
Parent Material: metamorphic, sedimentary, or igneous
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Malosma laurina-Eriogonum fasciculatum* Shrubland form an open to intermittent shrub layer (4–54%, mean 31.1%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–16%, mean 3.4%) at 0–1 m tall. Trees are occasionally emergent (0–4% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 4–55%, mean cover is 34.4%.

In this association, the shrub layer is characterized by *Eriogonum fasciculatum* and *Malosma laurina. Ceanothus megacarpus, Salvia mellifera, Heteromeles arbutifolia, Rhus ovata,* and *Adenostoma fasciculatum* are frequently included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is simple and may include *Brassica nigra, Melica imperfecta, Centaurea melitensis, Gnaphalium* sp., and *Bromus diandrus.*

Other Noteworthy Species:
Eriogonum crocatum was found in 1 of 58 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.1 (CNPS 2005). Federal listing is Species of Concern, and state listing is Rare (SAMO 2004).

Juglans californica was found in 1 of 58 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Brassica nigra, Centaurea melitensis, Avena, Bromus diandrus, Bromus madritensis, Avena barbata, Hirschfeldia incana, Nicotiana glauca, Brassica, Pennisetum setaceum, Acacia redolens, Avena fatua, Eucalyptus, Marrubium vulgare, Piptatherum miliaceum, Ricinus communis

Samples Used in Description: (n = 58)
AA0057cc, AA0095cc, AA0127cc, AA0167cc, AA0248cc, AA0249cc, AA0343, AA0347, AA0548, AA0584, AA0665, AA0703, AA0773, AA0833, AA0835, AA0840, AA0940, AA0985, AA1169, AA1170, AA1217, rap0162m, rap0234m, rap0238, rap0240m, rap0301, rap0311, rap0314, rap0319, rap0320, rap0322m, rap0323, rap0326, rap0327, rap0362, rap0381, rap0393, rap0394, rap0396, rap0430, rap0431, rap0451, rap0452m, rap0453, rap0479, rap0769, rap0770, rap0857, rap1143, rap1159, rap1183, rap1186, rap1630m, rap1763, rap2170, rap2293, rap2480, rap2674

Comments:
This association occurs fairly commonly on hot, dry southerly facing slopes. It is widespread throughout the study area in most of the subregions. It is perhaps most common in the upper elevation regions of the mountains where it tends to be restricted to very steep south-facing slopes**.**

Phases:
Malosma laurina-Eriogonum fasciculatum (Laurel Sumac-California Buckwheat) Phase [21423]
Malosma laurina-Eriogonum fasciculatum-Artemisia californica/Annual Grass-Herb (Laurel Sumac-California Buckwheat-California Sagebrush/Annual Grass-Herb) Phase [3382]

Malosma laurina-Eriogonum fasciculatum-Heteromeles arbutifolia-Ceanothus megacarpus (Laurel Sumac-California Buckwheat-Toyon-Big Pod Ceanothus) Phase [3383]

COMMON NAME	Laurel Sumac-California Buckwheat Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Malosma laurina* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains and from San Diego (Evens and San 2005) and western Riverside counties (Klein and Evens 2005). Information about its global distribution is not available without additional inventory, although it is likely to occur elsewhere in southern California below about 1,000 m.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
In the *Malosma laurina-Eriogonum fasciculatum* Association, both species are codominant in the shrub overstory. *Salvia apiana*, *Ceanothus leucodermis*, *Heteromeles arbutifolia*, *Baccharis pilularis*, and *Baccharis salicifolia* are examples of species that may occur as shrubs at low cover. The understory herbaceous layer is variable and usually dominated by nonnative species such as *Bromus madritensis, Avena fatua, Centaurea melitensis,* and *Hirschfeldia incana.*

Comments:
This association appears to have fairly constant environmental and species characteristics in all places it has been sampled in southern California.

Evens and San 2005, Klein and Evens 2005

Malosma laurina-Rhus ovata-Ceanothus megacarpus Shrubland Association

Laurel Sumac-Sugar Bush-Big Pod Ceanothus Shrubland Association
***Malosma laurina* Shrubland Alliance**
Laurel Sumac Shrubland Alliance

Mapping Code: 21415

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep, usually south-facing slopes at low elevations between 156–694 m. It is dominated by *Malosma laurina,* and *Rhus ovata* and *Ceanothus megacarpus* are subdominant or sometimes codominant with *Malosma*. The herbaceous layer is relatively simple and infrequent with species such as *Brassica nigra*, *Bromus, Marah macrocarpus,* and/or *Melica imperfecta.* The tree layer is also sometimes present and includes *Quercus agrifolia*.

Distribution:
This association is sampled in the Eastern Urban, Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 156–694 m, mean 306 m
Aspect: most often southwest and southeast, sometimes variable, and rarely northwest
Slope: range 15–38 degrees, mean 33.0 degrees
Topography (micro; macro): often undulating or flat, sometimes convex or concave; lower to upper slopes, rarely bottom or ridgetop
Litter Cover: 55% (one sample)
Small Rock Cover: range 5–30%, mean 17.5%
Large Rock Cover: range 0–5%, mean 2.0%
Bare Ground: range 15–32%, mean 23.7%
Parent Material: frequently igneous and sedimentary, sometimes depositional or metamorphic
Soil Texture: moderately fine sandy clay loam (one sample)

Vegetation Description:
Stands of *Malosma laurina-Rhus ovata-Ceanothus megacarpus* Shrubland form an open to intermittent shrub layer (12–51%, mean 38.4%). Shrubs commonly occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0–35%, mean 3.4%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.2%) hardwoods at 0–10 m tall. Total vegetation cover is 30–53%, mean cover is 41.6%.

In this association, the shrub layer is dominated openly to intermittently by *Malosma laurina,* and *Rhus ovata* and *Ceanothus megacarpus* are subdominant or sometimes codominant with *Malosma*. Other species characteristically present but at low cover are *Salvia mellifera* and *Adenostoma fasciculatum*, while a variety of other chaparral or coastal sage scrub species may also be present at low cover such as *Eriogonum fasciculatum* and *Heteromeles arbutifolia*. The herbaceous layer is relatively simple and infrequent with species such as *Brassica nigra*, *Bromus, Marah macrocarpus,* and/or *Melica imperfecta.* Occasionally, emergent trees may occur including *Quercus agrifolia*.

Malosma laurina-Salvia mellifera Shrubland Association

Laurel Sumac-Black Sage Shrubland Association
***Malosma laurina* Shrubland Alliance**
Laurel Sumac Shrubland Alliance

Mapping Code: 2148

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southeast- and southwest-facing slopes at low elevations between 17–756 m. It is characterized by a codominance of *Malosma laurina* and *Salvia mellifera* in the shrub layer. The herbaceous layer is generally insignificant. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Western Fog Zone, Dry Inland, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 17–756 m, mean 321.4 m
Aspect: southeast and southwest
Slope: range 15–40 degrees, mean 32 degrees
Topography (micro; macro): variable (all); lower slope to ridgetop
Litter Cover: range 15–35%, mean 25%
Small Rock Cover: range 0–50%, mean 23.7%
Large Rock Cover: range 0–5%, mean 1.3%
Bare Ground: range 14–65%, mean 37.7%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Malosma laurina-Salvia mellifera* Shrubland form an open to intermittent shrub layer (15–60%, mean 36.6%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–18%, mean 3.8%) at 0–1 m tall. Trees are frequently emergent (0–10% cover, mean 0.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 16–62%, mean cover is 40.8%.

In this association, the shrub layer is characterized by *Malosma laurina* and *Salvia mellifera*. *Eriogonum fasciculatum, Heteromeles arbutifolia,* and *Adenostoma fasciculatum* are often included in this layer. The tree layer is emergent and open and includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and may include *Brassica nigra, Centaurea melitensis, Bromus madritensis, Marah macrocarpus,* and *Bromus diandrus.*

None

COMMON NAME	Laurel Sumac-Black Sage Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Malosma laurina* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	61Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4?

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. It is also likely throughout south coastal California evidenced by the similar descriptions of types in Riverside and San Diego counties (Evens and San 2005, Klein and Evens 2005).

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
In the *Malosma laurina-Eriogonum fasciculatum-Salvia mellifera* Association described from western Riverside County by Klein and Evens (2005) and from San Diego County by Evens and San (2005), all three shrubs are usually codominant. Other chaparral and coastal sage species that are characteristically present at low cover include *Heteromeles arbutifolia*, *Artemisia californica*, *Adenostoma fasciculatum*, and *Yucca whipplei*. The herbaceous layer, which includes a variety of native and nonnative species, is usually dominated by *Bromus madritensis*.

Comments:
We suggest merging this association with the *Malosma laurina-Eriogonum fasciculatum-Salvia mellifera* Association of Klein and Evens (2005) and Evens and San (2005). The frequency of *Eriogonum fasciculatum* in the SAMO samples is 67%, high enough to be considered an adequate constancy by most standards.

References:
Evens and San 2005, Klein and Evens 2005

Mesembryanthemum spp.-*Carpobrotus* spp. Seminatural Shrubland Alliance

Ice Plant Shrubland Alliance

Mapping Code: 4720

Local Description

Summary:
This shrubland alliance occurs on abrupt to steep slopes with northeast aspect at low elevations between 2–46 m. It is dominated by the sprawling *Carpobrotus edulis* in the low shrub layer. The emergent tree layer includes occasional nonnative species such as *Schinus molle* and *Pinus* sp.

Distribution:
This alliance is sampled in the Immediate Coast and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 2–46 m, mean 17.6 m
Aspect: northeast
Slope: range 2–85 degrees, mean 28.5 degrees
Topography (micro; macro): flat or undulating; slope bottom to upper slope
Litter Cover: range 15–65%, mean 40%
Small Rock Cover: range 2–20%, mean 9.8%
Large Rock Cover: range 0–50%, mean 12.5%
Bare Ground: range 12–80%, mean 44.3%
Parent Material: quaternary or sedimentary
Soil Texture: sand to very fine loamy sand

Vegetation Description:
Stands of this shrubland alliance form an open shrub layer (7–20%, mean 12%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 0–2 m tall. The herbaceous layer is open to intermittent (13–40%, mean 26.2%) at 0.1–0.5 m tall. Trees are very occasionally emergent (0–0.4% cover, mean 0.66%) with conifers at 1–10 m and hardwoods at 0–5 m tall. Total vegetation cover is 23–51%, mean cover is 38.2%.

In this association, the shrub layer often includes *Artemisia californica* and *Encelia californica. Rhus integrifolia, Isocoma menziesii,* and *Coreopsis gigantea* are occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Schinus molle* and *Pinus* sp. at very low cover. The herbaceous layer is diverse and is characterized by *Carpobrotus edulis.* Other herbs sometimes include *Ambrosia chamissonis, Marah macrocarpus, Leymus condensatus, Brassica nigra,* and *Distichlis spicata. Mesembryanthemum crystallinum* is occasionally present.

Other Noteworthy Species:
Abronia umbellata was found in 1 of 6 surveys of this plant community, which is *Abronia umbellata* spp. *umbellata.* Regionally, the park considers this species as Rare (SAMO 2004). There is no state or global rank of this subspecies (CNPS 2005).

Nonnative Species:
Carpobrotus edulis, Brassica nigra, Myoporum laetum, Nicotiana glauca, Melilotus indicus, Ricinus communis, Bromus madritensis, Conyza canadensis, Anagallis arvensis, Atriplex semibaccata, Bromus diandrus, Bromus hordeaceus, Cakile maritima, Carpobrotus chilensis, Erodium, Foeniculum vulgare, Lamarckia aurea, Melilotus, Mesembryanthemum crystallinum, Nerium oleander, Pennisetum setaceum, Rumex crispus, Salsola tragus, Schinus molle, Sonchus

Samples Used in Description: (n = 6)
AA0672, rap0640, rap0648, rap1028, rap2777, rap2890rlv

Comments:
This is a widespread introduced vegetation type along the coast of California. It may be composed of one or more species of *Mesembryanthemum* or *Carpobrotus.* The most widespread species in the SAMO study area is *Carpobrotus edulis.* This is an invasive species that sprawls over dunes and coastal bluffs, smothering and shading out native species such as *Coreopsis gigantea, Ericameria ericoides, Ambrosia chamissonis*, and other native herbaceous species.

Phases:
None

COMMON NAME	Ice Plant Herbaceous Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.B. Perennial forb vegetation
PHYSIOGNOMIC GROUP	V.B.2. Temperate or subpolar perennial forb vegetation
PHYSIOGNOMIC SUBGROUP	V.B.2.N. Natural/Seminatural temperate or subpolar perennial forb vegetation
FORMATION	V.B.2.N.b. Low temperate or subpolar perennial forb vegetation
ALLIANCE	*Mesembryanthemum* spp.-*Carpobrotus* spp. *Seminatural Herbaceous Alliance* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5—This is an introduced alliance that usually strongly dominates the landscape to the exclusion of other native species.

Global Description

Distribution:
Ice plant mats occur along the northern, central, and southern California coasts, the Central Valley, and on the Channel Islands.

Nations:
United States

States or Provinces:
CA
Northern California coast (263A)—*Carpobrotus edulis* is the most common invader of dune habitats and is widespread on most dune systems.
Central California coast (261B)—*Mesembryanthemum* sp. and *Carpobrotus edulis* are both common on dune systems.
Southern California coast (261B)—*Mesembryanthemum* sp. and *Carpobrotus edulis* are both common on dune systems. On the Channel Islands, *Mesembryanthemum* sp. crowded out many native herbaceous and subshrub stands especially on the northern Channel Islands. Salt buildup from the leaves has effectively changed the soil chemistry of some of these stands and effectively excludes native species from recolonizing (Vivrette and Muller 1977).
Great Valley (262A)—Stands occur in Suisun marsh and in other delta areas of the Sacramento-San Joaquin delta (Keeler-Wolf et al. 2000).

Environmental Description:
Occurs on bluffs and disturbed land and sand dunes of the immediate coastline from sea level to 100 m elevation.

Vegetation Description:
Carpobrotus, *Mesembryanthemum* sp., or *Malephora crocea* is the sole or dominant herb in the ground canopy; *Abronia latifolia, Ambrosia chamissonis, Eriogonum latifolium, and/or Poa douglasii* may be present. Emergent shrubs may be present. Herbs are less than 50 cm; canopy is continuous.

Comments:
This treatment is broadly defined to recognize the importance of these introduced species in California's vegetation. The invasive character of several taxa in the *Aizoaceae* family is well appreciated in California, especially on coastal dune habitats. Three genera are included in this series. The *Jepson Manual* includes five taxa in the genera *Carpobrotus*, *Malephora*, and *Mesembryanthemum* as having naturalized in the state. These taxa have historically been placed in *Mesembryanthemum* but are now referred to as *Carpobrotus chilensis, C. edulis, Malephora crocea, Mesembryanthemum crystallinum, and M. nodiflorum.* All are invasive and replace native dune species, particularly members of the *Ambrosia chamissonis* and *Lupinus chamissonis-Ericameria ericoides* alliances.

Widely planted as a soil binder on embankments and as ornamental in coastal districts (Prescott and Venning 1984), ice plants (especially *Carpobrotus edulis*) can form impenetrable mats that crowd out other species. For years, local southern California fire departments have recommended ice plant to people with houses in fire-prone areas. Ice plant is also often used to control erosion. However, during years with a lot of rain, the succulent ice plant swells with water and can cause entire slopes to slide from the increased weight. *Carpobrotus edulis* is considered one of the most invasive wildland plants in California by the California Exotic Plants Pest Council (CalEPPC List of Exotic Pest Plants of Greatest Ecological Concern 2002 http://www.caleppc.org/info/99lista.html). Ice plant stands are being removed to restore native vegetation on the coastal dunes and enhance populations of rare species (Pickart and Sawyer 1998). Removal of these species is time consuming by hand-pulling (large mats can be removed by rolling them up like a carpet) and yet is easier and more cost-effective than removal of *Ammophila arenaria* (Albert 1996). Many California state park and national park lands along the coast are actively removing ice plant and replacing it with native dune species such as members of the *Ambrosia chamissonis* and *Lupinus chamissonis-Ericameria ericoides* alliances.

Mimulus aurantiacus Shrubland Association

Bush Monkey Flower Shrubland Association
***Mimulus aurantiacus* Shrubland Alliance**
Bush Monkey Flower Shrubland Alliance

Mapping Code: 2172

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northeast and northwest slopes at low elevations between 43–571 m. It is characterized by a strong dominance of *Mimulus aurantiacus* in the shrub layer. It has a presence of *Leymus condensatus* in most stands in the herbaceous layer, though this species is not considered characteristic. The emergent tree layer is usually absent but may include *Juglans californica, Eucalyptus* sp., *Pinus* sp., *Quercus agrifolia,* and *Platanus racemosa*.

Distribution:
This association is sampled in the Western Fog Zone, Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 43–571 m, mean 297 m
Aspect: northeast and northwest
Slope: range 15–40 degrees, mean 31.1 degrees
Topography (micro; macro): variable (all); lower slope to ridgetop
Litter Cover: range 5–75%, mean 38.8%
Small Rock Cover: range 2–25%, mean 14.3%
Large Rock Cover: range 0–8%, mean 1.7%
Bare Ground: range 10–35%, mean 21.7%
Parent Material: igneous or sedimentary
Soil Texture: coarse loamy sand to moderately fine clay loam

Vegetation Description:
Stands of *Mimulus aurantiacus* Shrubland form an open to intermittent shrub layer (13–63%, mean 43.6%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–22%, mean 3.6%) at 0–1 m tall. Trees are occasionally emergent (0–6% cover, mean 1.3%) with conifers at 0–10 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 32–70%, mean cover is 48.1%.

In this association, the shrub layer is characterized by *Mimulus aurantiacus, Artemisia californica,* and *Malosma laurina. Salvia leucophylla, Toxicodendron diversilobum,* and *Sambucus mexicana* are usually included in this layer. The tree layer is emergent and open and may include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and often includes *Leymus condensatus.* Other herbs may include *Melica imperfecta, Centaurea melitensis, Hirschfeldia incana,* and *Bromus madritensis.*

Comments:
This is the first time *Mimulus aurantiacus* has been identified at the alliance level in California. These stands are so heavily dominated by this species that there is little doubt that this is a distinct type. However, it is generally related to other coastal sage scrub alliances. It appears on generally steep, often somewhat unstable slopes in relatively mesic settings within the general vicinity of stands of *Artemisia californica* and *Salvia leucophylla* alliances. It also appears to be closely associated with recent burns in many cases and often occurs adjacent to stands of *Quercus agrifolia* woodland. In some cases, this type also appears to be associated with natural ground disturbance such as rockslides. Two phases have been described that have relatively higher cover of either *Malosma laurina* or *Salvia leucophylla*.

Phases:
Mimulus aurantiacus-Malosma laurina (Bush Monkey Flower-Laurel Sumac) Phase [2172]
Mimulus aurantiacus-Salvia leucophylla (Bush Monkey Flower-Purple Sage) Phase [2171]

COMMON NAME	Bush Monkey Flower Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Mimulus aurantiacus* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. The alliance is likely to occur throughout much of cismontane central and southern California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Small stands of this alliance have been seen as far north as Contra Costa County (Keeler-Wolf 2005, personal observation). These also occur on steep slopes and include *Artemisia californica*.

Opuntia spp.-Mixed Coastal Sage Scrub Shrubland Association

Coast Prickly Pear-Mixed Coastal Sage Scrub Shrubland Association
***Opuntia* spp. Shrubland Alliance**
Coast Prickly Pear Shrubland Alliance

Mapping Code: 2412

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southeast- and southwest-facing slopes at low elevations between 10–310 m. It is characterized by a dominance of *Opuntia* spp. (primarily *O. littoralis*, but occasionally *O. oricola* or both) in the shrub layer. The herbaceous layer is generally composed of a variety of nonnative species at low cover. The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Western Fog Zone, Dry Inland, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 10–310 m, mean 175.6 m
Aspect: southeast and southwest
Slope: range 15–40 degrees, mean 26.7 degrees
Topography (micro; macro): convex, flat, or undulating; lower slope to ridgetop
Litter Cover: range 15–55%, mean 28.6%
Small Rock Cover: range 2–50%, mean 17.5%
Large Rock Cover: range 0–70%, mean 7.6%
Bare Ground: range 0–75%, mean 33.9%
Parent Material: igneous
Soil Texture: fine clay to moderately fine clay loam

Vegetation Description:
Stands of *Opuntia* spp.-Mixed Coastal Sage Scrub Shrubland form an open continuous shrub layer (14–67%, mean 39%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–27%, mean 6%) at 0–2 m tall. Trees are frequently emergent (0–8% cover, mean 0.7%) with hardwoods at 0–10 m tall. Total vegetation cover is 21–75%, mean cover is 45.5%.

In this association, the shrub layer usually contains *Opuntia littoralis* and *Eriogonum fasciculatum*. *Artemisia californica, Yucca whipplei, Rhus integrifolia,* and *Encelia californica* are usually included in this layer. The tree layer is emergent and open and may infrequently include *Schinus molle* and *Quercus agrifolia* at low cover. The herbaceous layer is diverse and sometimes includes *Hirschfeldia incana, Bromus madritensis, Brassica nigra, Melica imperfecta, Dudleya pulverulenta,* and *Nassella pulchra*.

AA0003cc, AA0255cc, AA0283cc, AA0332, AA0382cc, AA0423, AA0613, AA0630, AA0679, rap0072, rap0090, rap1097, rap1129, rap1204m, rap1427, rap1428, rap1454, rap1757m, rap1758, rap1759, rap1760, rap1761, rap1767m, rap1831, rap2226, rap2251, rap2373, rap2492, rap2600, rap2648, rap2668, rap2695, rap2740, rap2746, rap2817, rap2863rlv, rap2899, rap2900, rap2901, rap2929

Comments:
This association describes the local succulent-dominated scrub. Difficulty in identifying the difference between *Opuntia littoralis* (and hybrids) from *O. oricola* (and hybrids) through binoculars has led to the nonspecific naming of the association. As a general rule, it appeared that the densest stands were dominated by *O. littoralis* and the more open stands often contained more *O. oricola. Nassella pulchra*, although not often found in mixed stands with shrubs, was sometimes seen in this type. Certain stands appear to have higher frequency of *Opuntia prolifera* (coastal cholla), although these did not segregate from the main cluster of samples in the quantitative analysis. The best and densest stands of this association occur on the northwestern portion of the study area usually on Conejo volcanics. These thickets are not to be taken lightly when considered for sampling.

Phases:
None

COMMON NAME	Coast Prickly Pear-Mixed Coastal Sage Scrub Shrubland Association
SYNONYM	Maritime Succulent Scrub (in part) (Holland 1996)
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Succulent extremely xeromorphic evergreen shrubland
ALLIANCE	*Opuntia littoralis* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2 (Hybrids and uncertain identification of key species beyond subgenus level)
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution are not available without additional inventory. Other similar stands of maritime cactus scrub occur south and east through the western Los Angeles Basin to San Diego County.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description

Comments:
These stands dominated by *playtopuntias* (either *Opuntia littoralis* or *O. oricola*) are not to be confused with the stands of more Baja California floristic affinities that occur in San Diego County and on some of the southern Channel Islands. The local stands provide excellent habitat for the coastal cactus wren. These stands are placed in the *O. littoralis* Alliance (c.f., Sawyer and Keeler-Wolf 1995) despite the uncertainty of some of the *Opuntia* species in some of the stands.

Holland 1986, Sawyer and Keeler-Wolf 1995

Prunus ilicifolia-Heteromeles arbutifolia Shrubland Association

Holly Leaf Cherry-Toyon Shrubland Association
***Prunus ilicifolia* Shrubland Alliance**
Holly Leaf Cherry Shrubland Alliance

Mapping Code: 2121

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northeast- and northwest-facing slopes at low elevations between 281–667 m. It is characterized by a dominance or codominance of *Prunus ilicifolia* along with *Heteromeles arbutifolia* in the shrub layer. The herbaceous layer may have native grasses, such as *Leymus condensatus* and *Melica imperfecta*, at low cover. The emergent tree layer includes *Umbellularia californica* and *Quercus agrifolia* at low cover in some of the stands.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Simi Hills Inland, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 281–667 m., mean 475 m
Aspect: northeast and northwest
Slope: range 15–45 degrees, mean 32.7 degrees
Topography (micro; macro): undulating; bottom to upper slope
Litter Cover: no data
Small Rock Cover: range 5–5%, mean 5%
Large Rock Cover: range 0–6%, mean 3%
Bare Ground: range 5–15%, mean 10%
Parent Material: sedimentary or igneous
Soil Texture: medium loam

Vegetation Description:
Stands of *Prunus ilicifolia-Heteromeles arbutifolia* Shrubland form an open to intermittent shrub layer (15–61%, mean 38.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0–40%, mean 5.6%) at 0–1 m tall. Trees are occasionally emergent (0–32% cover, mean 4.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 32–65%, mean cover is 48.4%.

In this association, the shrub layer is characterized by *Prunus ilicifolia* and *Heteromeles arbutifolia. Cercocarpus betuloides, Mimulus aurantiacus, Ceanothus oliganthus,* and *Toxicodendron diversilobum* are frequently included in this layer. The tree layer is emergent and open and may include *Umbellularia californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Melica imperfecta, Leymus condensatus,* and *Hirschfeldia incana.*

	MEIM	*Melica imperfecta*	36	3.8	0.2	40.0			
	LECO12	*Leymus condensatus*	27	0.2	0.2	2.0			

Other Noteworthy Species:
Juglans californica was found in 1 of 11 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Hirschfeldia incana, Avena, Centaurea melitensis, Carduus pycnocephalus, Centaurea solstitialis, Piptatherum miliaceum, Spartium junceum

Samples Used in Description: (n = 11)
AA0770, rap0553m, rap2229m, rap2324, rap2365, rap2402, rap2413, rap2422, rap2426, rap2624, rap2638

Comments:
This is one of the most mesic of the local chaparral associations. It tends to occur at higher elevations and only on northerly facing slopes, especially in narrow gorges or rock crevasses.

Phases:
None

COMMON NAME	Holly Leaf Cherry-Toyon Shrubland Association
SYNONYM	Toyon-Holly Leaf Cherry Alliance (Borchert et al. 2004)
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUB GROUP	Natural/Seminatural

FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Prunus ilicifolia* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
Central and south coast (including Santa Barbara, Ventura, and western Riverside counties), peninsular ranges (including western Riverside County: San Jacinto foothills, San Diego County: western foothills)

Nations:
United States

States or Provinces:
CA

Environmental Description:
Based on the western Riverside County description of Klein and Evens 2005, the following additional information may be provided on the environmental definition of this association: Elevation is usually below 1,000 m. Aspect is usually north-facing, and slopes are moderate to somewhat steep. Topography is usually concave, mid to upper slopes. Rock cover is relatively high in most stands, derived from granite, sedimentary, or metamorphic parent material. Soil texture is usually sandy loam to loam.

Vegetation Description:
This association has been described by Klein and Evens 2005 from western Riverside County. The following description is excerpted from their study: In the *Prunus ilicifolia-Heteromeles arbutifolia* Association, *Prunus ilicifolia* dominates or codominates in the overstory shrub layer, and *Heteromeles arbutifolia* is present at low cover. A variety of other species may intermix as subdominant shrubs, such as *Eriogonum fasciculatum*, *Toxicodendron diversilobum*, *Keckiella antirrhinoides*, *Adenostoma fasciculatum*, *Salvia apiana*, *and Salvia mellifera*. *Bowlesia incana*, *Marah macrocarpus*, *Muhlenbergia rigens*, *Leymus condensatus,* and nonnative *Bromus madritensis* are examples of species that may occur in the herb layer. This association has also been described from San Diego County (Evens and San 2005) with similar characteristics.

Comments:
Elsewhere *Prunus ilicifolia* stands may reach great age and become semiarborescent (sensu mainland cherry stands Sawyer and Keeler-Wolf 1995). Most of the SAMO stands appear to have burned in the relatively recent past and are multistemmed. Borchert et al. 2004 describe this same vegetation type as a *Prunus ilicifolia-Heteromeles arbutifolia* Alliance, and they separate it from two other similar alliances: the *Ceanothus megacarpus-Prunus ilicifolia* Alliance and the *Cercocarpus betuloides-Prunus ilicifolia* Alliance. All three of these mixed alliances will be treated by Sawyer et al. (2006 MS) as a part of the *Prunus ilicifolia* Alliance, which allows for codominance of other species with *P. ilicifolia*. The rationale behind this involves similar mesic

conditions for all of these and, apparently, low variance within each one of these types not requiring further differentiation into alliances but into associations of the *Prunus ilicifolia* Alliance.

Quercus berberidifolia Shrubland Association

Scrub Oak Shrubland Association
***Quercus berberidifolia* Shrubland Alliance**
Scrub Oak Shrubland Alliance

Mapping Code: 2161

Local Description

Summary:
This shrubland association occurs on gentle to very steep northwest- and northeast-facing slopes at low to middle elevations between 119–783 m. It is characterized by strong dominance of *Quercus berberidifolia* in the shrub layer. The herbaceous layer is sparse and has no characteristic species. The emergent tree layer includes *Quercus agrifolia* in some stands.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, Dry Inland, Eastern Urban, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 119–783 m, mean 342.2 m
Aspect: northwest and northeast
Slope: range 1–55 degrees, mean 23.6 degrees
Topography (micro; macro): variable (all); bottom to ridgetop
Litter Cover: range 50–80%, mean 68.3%
Small Rock Cover: range 0–30%, mean 6.6%
Large Rock Cover: range 0–80%, mean 3.4%
Bare Ground: range 0–42%, mean 15.3%
Parent Material: sedimentary
Soil Texture: coarse loamy sand to fine clay

Vegetation Description:
Stands of *Quercus berberidifolia* Shrubland form an open to continuous shrub layer (8–70%, mean 51.1%). Shrubs occur in two different strata with low shrubs at 0–5 m tall and tall shrubs at 1–10 m tall. The herbaceous layer is open to intermittent (0–48%, mean 3%) at 0–1 m tall. Trees are occasionally emergent (0–24% cover, mean 2.1%) with conifers at 0–10 m tall and hardwoods at 0–15 m tall. Total vegetation cover is 15–78%, mean cover is 55.7%.

In this association, the shrub layer is dominated by *Quercus berberidifolia. Heteromeles arbutifolia* also often occurs in the shrub layer. Other shrubs occasionally include *Adenostoma fasciculatum*, *Rhus ovata, Salvia leucophylla, Ceanothus spinosus, Toxicodendron diversilobum,* and *Malosma laurina*. The tree layer is emergent and open and sometimes includes *Quercus agrifolia, Juglans californica,* and *Quercus lobata* at low cover. The herbaceous layer is diverse and sometimes includes *Centaurea melitensis, Bromus madritensis, Brassica nigra, Bromus diandrus, Marah macrocarpus, Hemizonia fasciculata, Melica imperfecta,* and *Hirschfeldia incana.*

Other Noteworthy Species:
Baccharis malibuensis was found in 1 of 54 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 3-3-3. Global rank is G1, and state rank is S1.1 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Calochortus catalinae was found in 1 of 54 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 1 of 54 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Bromus diandrus, Bromus madritensis, Brassica nigra, Hirschfeldia incana, Avena, Avena fatua, Bromus hordeaceus, Marrubium vulgare, Nicotiana glauca, Stellaria media, Carduus pycnocephalus, Eucalyptus, Galium aparine, Robinia, Schinus molle, Spartium junceum, Anagallis arvensis, Centaurea solstitialis, Conium maculatum, Conyza canadensis, Erodium cicutarium, Foeniculum vulgare, Melilotus, Melilotus indicus, Phoenix canariensis, Piptatherum miliaceum, Salsola tragus, Senecio argutus

Samples Used in Description: (n = 54)
AA0021cc, AA0040cc, AA0085cc, AA0086cc, AA0087cc, AA0399cc, AA0471cc, AA0756cc, AA0975, AA0994, AA1011, AA1094, AA1134, AA1179, rap0248, rap0291, rap0298, rap0299, rap0306, rap0336, rap0337, rap0340, rap0454, rap0461m, rap0505, rap0602, rap0830, rap1583, rap1621, rap1633, rap1637, rap1640m, rap1792, rap1826, rap1897m, rap1899, rap1915, rap2002, rap2004, rap2153, rap2155, rap2195, rap2210, rap2241, rap2316, rap2377, rap2445, rap2679, rap2687, rap2815, rap2832, rap2835, rap2843, rap2912

Comments:
This association is a common mesic chaparral locally and has been found in many other parts of central and southern California. It is easily distinguished from the related *Q. berberidifolia-Ceanothus spinosus* Association and the *Q. berberidifolia-Cercocarpus betuloides* Association. In this association, *Q. berberidifolia* usually forms a dense cover, with neither *C. betuloides* nor *C. spinosus* even approaching codominance. Additional phases have been identified with relatively higher cover of either *Heteromeles arbutifolia* or *Adenostoma fasciculatum*. However, both of these species tend to remain as subdominants to *Q. berberidifolia*.

Phases:
Quercus berberidifolia-Adenostoma fasciculatum (Scrub Oak-Chamise) Phase [2163]
Quercus berberidifolia-Heteromeles arbutifolia (Scrub Oak Toyon) Phase [2164]
Quercus berberidifolia (Scrub Oak) Phase [2161]

COMMON NAME	Scrub Oak Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Quercus berberidifolia* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains as well as San Diego County (Evens and San 2005), Riverside County (Klein and Evens 2005), other parts of the eastern transverse and peninsular ranges (Gordon and White 1994), and north and westward to the northern range districts of the Los Padres National Forest (Borchert et al. 2004). It is likely that the same association occurs north well into the central and inner northern coast ranges (Thorne et al. 2004, Sawyer and Keeler-Wolf 1995).

Nations:
United States

States or Provinces:
CA

Environmental Description:
Additional information summary from Klein and Evens (2005) for the *Q. berberidifolia* Alliance follows:

Elevation is below 1,500 m. Aspect is usually northerly and less often southerly. It is found on moderate to steep slopes, and topography is variable. Ground cover especially contains a

moderate to high litter content. Parent material is more often sedimentary, less often granitic, metamorphic, gabbro-diorite, or metavolcanic. Soil texture varies from loamy sand to clay.

Vegetation Description:
Quercus berberidifolia is the sole dominant shrub in the intermittent to continuous shrub layer. A variety of other chaparral, coastal sage, and desert shrub species may be present, the most common being *Adenostoma fasciculatum*, *Salvia mellifera, Heteromeles arbutifolia, Rhamnus crocea,* and *Eriogonum fasciculatum.* The most common herb species include nonnative annuals *Hirschfeldia incana*, *Bromus diandrus*, *Bromus madritensis*, or *Bromus tectorum*, though natives such as *Marah macrocarpus* and *Paeonia californica* are also usually present (Klein and Evens 2005, Evens and San 2005).

Comments:
There may be some minor local variation in this widespread association based on locally distributed, low-constancy species. Sufficient sampling has yet to be done in the northern part of its range.

References:

Quercus berberidifolia-Ceanothus spinosus Shrubland Association

Scrub Oak-Greenbark Ceanothus Shrubland Association
***Quercus berberidifolia* Shrubland Alliance**
Scrub Oak Shrubland Alliance

Mapping Code: 2167

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep slopes of variable aspect at low elevations between 230–563 m. It is characterized by a codominance of *Quercus berberidifolia* and *Ceanothus spinosus* in the shrub layer. The simple herbaceous layer often has the vine *Marah macrocarpa*. The emergent tree layer occasionally includes *Quercus agrifolia*.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 230–563 m, mean 429.4 m
Aspect: variable
Slope: range 15–35 degrees, mean 26 degrees
Topography (micro; macro): flat or undulating; lower to upper slope
Litter Cover: no data
Small Rock Cover: range 3–15%, mean 7.3%
Large Rock Cover: range 0–2%, mean 1%
Bare Ground: range 10–20%, mean 13%
Parent Material: sedimentary, igneous, metamorphic, and quaternary
Soil Texture: coarse loamy sand to moderately fine silty clay loam

Vegetation Description:
Stands of *Quercus berberidifolia-Ceanothus spinosus* Shrubland form an intermittent to continuous shrub layer (41–65%, mean 56.3%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–33%, mean 3.9%) at 0–0.5 m tall. Trees are occasionally emergent (0–5% cover, mean 1%) with hardwoods at 0–10 m tall. Total vegetation cover is 45–65%, mean cover is 59.3%.

In this association, the shrub layer is characterized by *Quercus berberidifolia, Ceanothus spinosus, Heteromeles arbutifolia,* and *Adenostoma fasciculatum. Rhus ovata, Cercocarpus betuloides, Malosma laurina, Rhamnus ilicifolia,* and *Salvia mellifera* are occasionally included in this layer. The tree layer is emergent and open and may occasionally include *Quercus agrifolia* and *Umbellularia californica* at low cover. The herbaceous layer is simple and sometimes includes *Marah macrocarpus, Bromus madritensis, Centaurea melitensis, Piptatherum miliaceum,* and *Stellaria media*.

Comments:
This is an endemic association to the western transverse ranges, probably centered in the Santa Monica Mountains. It differs from the related *Ceanothus spinosus* Alliance by having dominance to codominance of *Q. berberidifolia*. It stands to reason that these two shrub species would comingle because both are mesophytic and resprout after fire.

Quercus berberidifolia-Adenostoma fasciculatum Shrubland Association

Scrub Oak-Chamise-Shrubland Association
***Quercus berberidifolia-Adenostoma fasciculatum* Shrubland Alliance**
Scrub Oak-Chamise Shrubland Alliance

Mapping Code: 2581

Local Description

Summary:
This shrubland association occurs on gentle to steep slopes of variable aspect at low elevations between 299–764 m. It is dominated by *Adenostoma fasciculatum* and *Quercus berberidifolia* in the shrub layer with a sparse herbaceous layer. The emergent tree layer includes *Quercus agrifolia.*

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Eastern Urban regions of the study area.

Environmental Description:
Elevation: range 299–764 m, mean 451 m
Aspect: variable
Slope: range 2–40 degrees, mean 19.3 degrees
Topography (micro; macro): flat, undulating, concave, or convex; mid slope to ridgetop
Litter Cover: range 35–35%, mean 35%
Small Rock Cover: range 5–45%, mean 22.7%
Large Rock Cover: range 0–12%, mean 3.7%
Bare Ground: range 10–38%, mean 21.9%
Parent Material: sedimentary or igneous, occasionally quaternary
Soil Texture: moderately fine sandy to silty clay loam

Vegetation Description:
Stands of *Adenostoma fasciculatum-Quercus berberidifolia* Shrubland form an open to intermittent shrub layer (20–55%, mean 42.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–18%, mean 2.2%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.2%) with hardwoods at 0–15 m tall. Total vegetation cover is 20–55%, mean cover is 44.9%.

In this association, the shrub layer is characterized by *Adenostoma fasciculatum* and *Quercus berberidifolia. Salvia mellifera* and *Heteromeles arbutifolia* are usually included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Marah macrocarpus, Centaurea melitensis, Bromus madritensis*, and *Nassella lepida*.

Other Noteworthy Species:
Calochortus plummerae was found in 1 of 20 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, CNPS R-E-D Code is 2-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 1 of 20 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Bromus madritensis, Avena fatua, Avena, Brassica nigra, Bromus diandrus, Bromus hordeaceus, Eucalyptus, Schinus molle

Samples Used in Description: (n = 20)
AA0312cc, AA0636, rap0264, rap0268, rap0275, rap0331, rap0503m, rap0858, rap1636, rap1986, rap2070, rap2097, rap2194m, rap2233, rap2240, rap2351, rap2417, rap2587, rap2664, rap2792

Comments:
Stands of this association in the Santa Monica Mountains tend to be dominated by *Adenostoma fasciculatum* with a lower cover (on the average less than half as much) of *Q. berberidifolia.* This is in contrast to stands described by Gordon and White 1994, Borchert et al. 2004, Evens and San 2005, and Klein and Evens 2005 where both species codominate usually at > 20% cover each. Because many species are shared and the environmental conditions are similar, we

decided to maintain a conservative approach to naming this association rather than describing a new association of the *Adenostoma fasciculatum* alliance with *Q. berberidifolia* as a subordinate.

Phases:
None

COMMON NAME	Chamise-Scrub Oak Shrubland Association

CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains and several other areas within the central and southern coastal California region. This includes western Riverside (Klein and Evens 2005), San Diego (Evens and San 2005), Los Angeles, Santa Barbara, San Luis Obispo, Ventura, and Monterey counties (Borchert et al. 2004, Gordon and White 1994). It is probably most extensive in the peninsular ranges (western Riverside County: Santa Ana Mountains, San Jacinto Mountains and foothills; San Diego County: western foothills and Palomar-Cuyamaca Peak regions).

Nations:
United States

States or Provinces:
CA

Environmental Description:
In the Los Padres National Forest of Monterey and San Luis Obispo counties (Borchert et al. 2004), the scrub oak-chamise alliance is common in the interior portions of the coast ranges, especially in the Sierra Madre Mountains and Garcia Mountains of the San Luis Obispo Ranger District and in the eastern Monterey Ranger District. Most stands occur below elevations of 1,100 m on middle and upper slope positions. Aspects vary but tend to be north facing. Slopes are generally greater than 20 degrees.

Vegetation Description:
In addition to the codominance of the two main species, a variety of coastal sage and chaparral shrubs (e.g., *Rhamnus ilicifolia*, *Salvia mellifera, Lonicera subspicata*, *Rhus ovata*, *Heteromeles*

arbutifolia, *Eriogonum fasciculatum*) may occur at low cover in the open to continuous shrub layer.

Comments:
There is some confusion about the proper nomenclature for this association and the alliance it is within. The confusion comes from the inversion of the names of the two dominant and characteristic species. The *Adenostoma fasciculatum-Quercus berberidifolia* Association has been described by Gordon and White 1994, while the *Quercus berberidifolia-Adenostoma fasciculatum* Alliance and Association have been described by Sawyer and Keeler-Wolf 1995, Evens and San 2005, and Klein and Evens 2005. Both apparently refer to the same vegetation. The former association has been defined to describe the stands where *A. fasciculatum* clearly dominates but *Q. berberidifolia* is present in low cover. This situation is more the norm for the Santa Monica Mountains stands. However, we have chosen to subsume this as an association within the broader mixed *Q. berberidifolia-A. fasciculatum* Alliance because of the overall similarity in species composition and environmental variables.

Quercus berberidifolia-Cercocarpus betuloides Shrubland Association

Scrub Oak-Birch Leaf Mountain Mahogany Shrubland Association
***Quercus berberidifolia-Cercocarpus betuloides* Shrubland Alliance**
Scrub Oak-Birch Leaf Mountain Mahogany Shrubland Alliance

Mapping Code: 2591

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northeast- and northwest-facing slopes at low elevations between 223–314 m. It is characterized by dominance to codominance of *Quercus berberidifolia* with subdominance to codominance of *Cercocarpus betuloides* in the shrub layer. The herbaceous layer may have mesophytic species such as *Melica imperfecta* and *Marah macrocarpa*, but no characteristic herbs have been identified. The emergent tree layer may include *Quercus agrifolia, Juglans californica,* and small trees of *Fraxinus dipetala*.

Distribution:
This association is sampled in the Eastern Urban and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 223–314 m, mean 282.4 m
Aspect: northeast and northwest
Slope: range 15–35 degrees, mean 29.7 degrees
Topography (micro; macro): undulating or flat; lower to upper slope
Litter Cover: range 60–65%, mean 62.5%
Small Rock Cover: range 0–10%, mean 5%
Large Rock Cover: no data
Bare Ground: range 0–45%, mean 26.3%
Parent Material: igneous
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of *Quercus berberidifolia-Cercocarpus betuloides* Shrubland form an intermittent to continuous shrub layer (46–62%, mean 51%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 2–5 m tall. The herbaceous layer is open (0–7%, mean 2%) at 0–0.5 m tall. Trees are occasionally emergent (0–15% cover, mean 3%) with hardwoods at 0–10 m tall. Total vegetation cover is 48–65%, mean cover is 55.8%.

In this association, the shrub layer is characterized by *Quercus berberidifolia, Cercocarpus betuloides, Rhus ovata,* and *Heteromeles arbutifolia*. *Malosma laurina, Ceanothus spinosus*, *Toxicodendron diversilobum, Ceanothus cuneatus, Mimulus aurantiacus,* and *Adenostoma fasciculatum* are occasionally included in this layer. The tree layer is emergent and open and can include *Quercus agrifolia, Juglans californica,* and *Fraxinus dipetala* at low cover. The herbaceous layer is simple and may include *Melica imperfecta, Centaurea melitensis*, and *Marah macrocarpus.*

Other Noteworthy Species:
Juglans californica was found in 3 of 8 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Senecio mikanioides, Bromus madritensis, Eucalyptus, Galium aparine

Samples Used in Description: (n = 8)
AA0156cc, AA0590, AA1183, rap0739m, rap0741, rap0742, rap2254m, rap2806

Comments:
This vegetation type is most frequently seen in inland, low-elevation locales such as the Malibu Creek drainage.

Phases:
None

COMMON NAME	Scrub Oak-Birch Leaf Mountain Mahogany Shrubland Association
SYNONYM	*Quercus berberidifolia-Cercocarpus betuloides* Alliance (Gordon and White, Sawyer and Keeler-Wolf 1995)
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland

PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Quercus berberidifolia-Cercocarpus betuloides* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. The alliance is known from the Main Division of the Los Padres National Forest (Borchert et al. 2004) and western Riverside County (Klein and Evens 2005).

Nations:
United States

States or Provinces:
CA

Environmental Description:
The following information has been provided for the broader alliance concept of *Q. berberidifolia-C. betuloides* as described by Klein and Evens 2005. It includes further variation not present in the Santa Monica Mountains study area: Elevation is below 1,500 m with aspect usually northerly, rarely southerly. Slope is moderate to steep, and topography is variable. Parent material is more often granite, less often metamorphic, sedimentary, gabbro, diorite, or metavolcanic. Soil texture is more often sandy loam but varies from sandy loam to clay loam.

Vegetation Description:
Klein and Evens 2005 have 17 samples to describe the *Q. berberidifolia-Cercocarpus betuloides* Alliance in western Riverside County as follows: Stands of *Quercus berberidifolia-Cercocarpus betuloides* Shrubland form an open to continuous shrub layer (25–87%), where the two species may be codominant or either species may be subdominant to the other. The shrub layer is frequently in two different strata, with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (0.2–60%) at 0–1 m tall and includes a variety of native and nonnative herbs. Total vegetation cover is 55–89%.

Comments:
This association has been treated as an alliance/series by Gordon and White 1994, Sawyer and Keeler-Wolf 1995, and Borchert et al. 2004. It is treated as the type association here and in Sawyer et al. 2006 MS. Further variation of stands with both *Q. berberidifolia* and *C. betuloides* was described by Klein and Evens 2005. These include the *Quercus berberidifolia-Cercocarpus betuloides-Arctostaphylos glauca* Association and the *Quercus berberidifolia-Cercocarpus betuloides-Ceanothus crassifolius* Association. These also could be thought of as associations within the *Quercus berberidifolia* Alliance (*sensu lato*).

Quercus wislizenii var. *frutescens* Shrubland Alliance

Scrub Interior Live Oak Shrubland Alliance

Mapping Code: 2560

Local Description

Summary:
This shrubland alliance occurs on somewhat steep northeast- and northwest-facing slopes at mid elevations between 623 and 690 m. It is dominated by *Quercus wislizeni* var. *frutescens* in the shrub layer with scattered shrubs of *Ceanothus oliganthus*. The emergent tree layer includes scattered *Quercus agrifolia.*

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: range 623–690 m, mean 656.5 m
Aspect: northeast and northwest
Slope: range 15–23 degrees, mean 19 degrees
Topography (micro; macro): convex or concave; upper slope
Litter Cover: 30%
Small Rock Cover: 10%
Large Rock Cover: 45%
Bare Ground: 3%
Parent Material: quaternary and sedimentary
Soil Texture: no data

Vegetation Description:
Stands of this shrubland alliance form an open to intermittent shrub layer (18–50%, mean 34%). Shrubs occur in two different strata, with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is bare (0%). Trees are occasionally emergent (5–16% cover, mean 10.5%) with hardwoods at 1–10 m tall. Total vegetation cover is 34–55%, mean cover is 44.5%.

In this association, the shrub layer is characterized by *Quercus wislizeni* var. *frutescens, Adenostoma fasciculatum, Arctostaphylos glandulosa, Ceanothus oliganthus,* and *Heteromeles arbutifolia. Quercus berberidifolia* and *Adenostoma sparsifolium* are occasionally included in this layer. The tree layer is emergent and open and includes *Quercus agrifolia* at low cover. The herbaceous layer is simple, with *Pellaea* sp. as the most abundant.

ALLIANCE	*Quercus wislizenii* var. *frutescens* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This shrubland of cismontane California occurs in the inner north coast range; the foothills of the Cascades and Sierra Nevada Mountains; and the montane Sierra Nevada, transverse, and peninsular ranges.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This shrubland alliance of cismontane California grows between 300 and 1,850 m elevation on all slopes. Substrates are usually derived from bedrock or alluvium and may be rocky. The climate is Mediterranean with cool, moist winters and warm, dry summers. Most precipitation falls as rain between November and May. Yearly rainfall totals vary between 40 and 200 cm in the range of this alliance.

Vegetation Description:
This California chaparral community is dominated by at least 60% relative cover of *Quercus wislizeni*. Other shrubs present may include *Arctostaphylos glauca, Arctostaphylos glandulosa, Cercocarpus montanus* var. *glaber, Aesculus californica, Rhamnus californica, Juniperus californica, Quercus chrysolepis, Adenostoma fasciculatum, Ceanothus leucodermis, Prunus ilicifolia* ssp*. ilicifolia, Rhamnus ilicifolia, Toxicodendron diversilobum, Quercus berberidifolia,* and *Ceanothus cuneatus.* Emergent individual trees could include *Pinus coulteri, Pinus sabiniana,* and *Pinus attenuata*.

Comments:
None

Rosa californica Shrubland Alliance
California Rose Shrubland Alliance

Mapping Code: 3010

Local Description

Summary:
One stand of this shrubland alliance occurs on a gentle riparian stream terrace at low elevation (503 m). It is solely dominated by *Rosa californica* in the shrub layer. *Artemisia californica* and *Hirschfeldia incana* occur at low cover in the herbaceous layer, and no species are recorded in the tree layer.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: 503 m
Aspect: flat/none
Slope: 2 degrees
Topography (micro; macro): flat; lower slope/stream terrace
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: igneous
Soil Texture: no data

Vegetation Description:
Stands of *Rosa californica* Shrubland form an open shrub layer (25%). Shrubs occur in two different strata with low shrubs at 0.5–1 m tall and tall shrubs at 1–2 m tall. The herbaceous layer is sparse to open (3%) at 0.5–1 m tall. The tree layer is not recorded. Total vegetation cover is 28%.

In this alliance, the shrub layer is dominated solely by *Rosa californica*. *Sambucus mexicana* exhibits low cover, and other coastal sage species are present at sparse cover. The herbaceous layer is simple with *Artemisia douglasiana* and *Hirschfeldia incana* occurring at low cover, and the tree layer is absent.

ALLIANCE	*Rosa californica* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This alliance has been recorded in southern California from San Diego and Ventura counties and in central California in Suisun Marsh; however, its distribution is not fully known.

Nations:
United States

States or Provinces:
CA

Environmental Description:
Stands usually occur directly adjacent to stream channels on flat to steep slopes of the stream terraces/banks.

Vegetation Description:
The shrub layer is an open to continuous canopy with sole dominance by *Rosa californica*. Associated shrub species may include *Sambucus mexicana, Symphoricarpos mollis,* and *Salix* sp. The herbaceous layer is usually open and may include wetland species such as *Artemisia douglasiana* or *Urtica dioica*, though they may also include upland species such as *Hirschfeldia incana, Brassica,* and *Bromus* spp. Trees are usually absent.

Rhus integrifolia Shrubland Association

Lemonade Berry Shrubland Association
***Rhus integrifolia* Shrubland Alliance**
Lemonade Berry Shrubland Alliance

Mapping Code: 2153

Local Description

Summary:
This shrubland association occurs on gentle to abrupt slopes of variable aspect at low elevations between 5–750 m. It is characterized by a strong dominance of *Rhus integrifolia* in the shrub layer. The herbaceous layer is insignificant but commonly contains *Leymus condensatus.* The emergent tree layer is usually absent.

Distribution:
This association is sampled in the Western Fog Zone, Immediate Coast, Eastern Urban, Upper Elevation Santa Monica Mountains, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 5–750 m, mean 191.6 m
Aspect: variable
Slope: range 2–75 degrees, mean 30.4 degrees
Topography (micro; macro): variable (all); bottom to ridgetop
Litter Cover: range 25–90%, mean 40.6%
Small Rock Cover: range 0–50%, mean 17%
Large Rock Cover: range 0–55%, mean 9.8%
Bare Ground: range 5–50%, mean 25.1%
Parent Material: igneous
Soil Texture: coarse sand to moderately fine clay loam

Vegetation Description:
Stands of *Rhus integrifolia* Shrubland form an open to continuous shrub layer (6–65%, mean 36.1%). Shrubs occur in two different strata with low shrubs at 0-2 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open to intermittent (0–42%, mean 6.7%) at 0–2 m tall. Trees are occasionally emergent (0–14% cover, mean 1.4%) with conifers at 0–15 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 10–68%, mean cover is 44.3%.

In this association, the shrub layer is characterized by *Rhus integrifolia. Artemisia californica* and *Malosma laurina* are frequently included in this layer. Other shrubs sometimes present include *Salvia mellifera, Heteromeles arbutifolia, Encelia californica, Malacothamnus fasciculatus, Yucca whipplei,* and *Sambucus mexicana*. The tree layer is emergent and open and may infrequently include *Quercus agrifolia, Juglans californica*, and *Schinus molle* at low cover. The herbaceous layer is diverse and sometimes includes *Leymus condensatus, Centaurea melitensis,* and *Melica imperfecta.*

Comments:
This association of the *R. integrifolia* Alliance is characterized by a strong dominance of lemonade berry. As with other associations in this alliance, it tends to occur close to the coast on steep south-facing slopes. Three phases have been identified. In addition to the pure phase, one is a mixture of the dominant with a subdominance of *Heteromeles arbutifolia,* and the other is a seral postfire phase with *Malacothamnus fasciculatus.* It is similar to the *R. integrifolia-Artemisia californica-Eriogonum cinereum* Association except that the cover of *R. integrifolia* is higher and the constancy of *Eriogonum cinereum* and *A. californica* is substantially lower. This type is occasionally seen in highly disturbed fragments within urbanized areas.

Phases:
Rhus integrifolia-Heteromeles arbutifolia (Lemonade Berry-Toyon) Phase [2158]
Rhus integrifolia-Malacothamnus fasciculatus (Lemonade Berry-Bush Mallow) Phase [7153]
Rhus integrifolia (Lemonade Berry) Phase [2153]

Local Description

Summary:
This shrubland association occurs on moderate to abrupt slopes of variable aspect at low elevations between 4–280 m. It is characterized by a dominance of *Rhus integrifolia* and a subdominance of *Artemisia californica* and *Eriogonum cinereum* in the shrub layer. The herbaceous layer is sparse and composed mostly of nonnative grasses and herbs. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Western Fog Zone, Immediate Coast, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 4–280 m, mean 101.8 m
Aspect: variable
Slope: range 8–70 degrees, mean 32.8 degrees
Topography (micro; macro): variable (all); bottom to ridgetop
Litter Cover: range 15–35%, mean 20.6%
Small Rock Cover: range 4–60%, mean 26.4%
Large Rock Cover: range 0–90%, mean 19.1%
Bare Ground: range 1–70%, mean 24.4%
Parent Material: igneous or sedimentary
Soil Texture: coarse loamy sand to moderately fine clay loam

Vegetation Description:
Stands of *Rhus integrifolia-Artemisia californica-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (6–58%, mean 29.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (1–26%, mean 6.7%) at 0–1 m tall. Trees are occasionally emergent (0–4% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 7–72%, mean cover is 35.2%.

In this association, the shrub layer is characterized by *Rhus integrifolia, Artemisia californica,* and *Eriogonum cinereum. Malosma laurina, Yucca whipplei,* and *Salvia leucophylla* are frequently included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Leymus condensatus* and *Pennisetum setaceum*.

	CEME2	*Centaurea melitensis*	22	0.6	0.2	4.0		X	

Other Noteworthy Species:
Calochortus catalinae was found in 3 of 36 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Pennisetum setaceum, Centaurea melitensis, Bromus madritensis, Brassica nigra, Hirschfeldia incana, Avena, Avena fatua, Erodium cicutarium, Nicotiana glauca, Anagallis arvensis, Arundo donax, Brassica, Bromus hordeaceus, Erodium, Foeniculum vulgare, Medicago polymorpha, Melilotus indicus, Myoporum laetum, Ricinus communis, Silybum marianum

Samples Used in Description: (n = 36)
AA0121cc, AA0176cc, AA0215cc, AA0509, AA0617, AA0621, AA0744cc, AA0777, AA0781, AA0870, AA0907, AA0960, AA1014, AA1015, AA1033, rap0511, rap0651, rap0663, rap0665, rap0883, rap0941m, rap1095, rap1096, rap1109m, rap1166, rap1202, rap1277, rap1464, rap1472, rap1478, rap1791m, rap2109, rap2375, rap2537rlv, rap2553, rap2822

Comments:
There is some question about how different this association is from the other two associations defined in this alliance. *R. integrifolia* occupies a fairly distinct setting close to the immediate coast at low elevations and usually on steep slopes including ocean bluffs. The matrix species include *A. californica* and *E. cinereum* to varying degrees in most of the 97 samples taken in this alliance. Another approach to classification of this alliance may be to aggregate all stands in the SAMO study area into an *R. integrifolia-Artemisia californica-Eriogonum cinereum* Association and reduce the additional types described as associations herein to phases. Further analysis of other stands of this alliance in southern California will clarify this issue.

Phases:
Rhus integrifolia-Artemisia californica-Salvia leucophylla (Lemonade Berry-California Sagebrush-Purple Sage) Phase [2155]
Rhus integrifolia-Eriogonum cinereum-Yucca whipplei-Coreopsis gigantea (Lemonade Berry-Ashy Buckwheat-Chaparral Yucca-Giant Coreopsis) Phase [7155]

COMMON NAME	Lemonade Berry-California Sagebrush-Ashy Buckwheat Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	Shrubland
PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Temperate broad-leaved evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Sclerophyllous temperate broad-leaved evergreen shrubland
ALLIANCE	*Rhus integrifolia* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. This association is probably endemic to the western transverse ranges of southern California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
A similar association, the *Rhus integrifolia-Salvia mellifera-Artemisia californica* Association, has been described by Evens and San 2005 in coastal San Diego County. It lacks *Eriogonum cinereum*.

Evens and San 2005

Rhus integrifolia-Opuntia spp.-*Eriogonum cinereum* Shrubland Association

Lemonade Berry-Coast Prickly Pear-Ashy Buckwheat Shrubland Association
***Rhus integrifolia* Shrubland Alliance**
Lemonade Berry Shrubland Alliance

Mapping Code: 2151

Local Description

Summary:
This shrubland association occurs on somewhat steep to very steep southeast- and southwest-facing slopes at low elevations between 3–251 m. It is characterized by a codominance of *Rhus integrifolia* and *Opuntia littoralis* and a constant subdominance of *Eriogonum cinereum* in the shrub layer. The herbaceous layer is composed of a mixture of native and nonnative species.

Distribution:
This association is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: range 3–251 m, mean 78.6 m.
Aspect: southeast and southwest
Slope: range 15–60 degrees, mean 35.8 degrees
Topography (micro; macro): undulating, flat, or concave; lower to upper slope
Litter Cover: no data
Small Rock Cover: range 15–40%, mean 27.5%
Large Rock Cover: range 1–2%, mean 1.5%
Bare Ground: range 5–20%, mean 12.5%
Parent Material: igneous
Soil Texture: clay

Vegetation Description:
Stands of *Rhus integrifolia-Opuntia* spp.*-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (29–60%, mean 42.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–6%, mean 3.5%) at 0–0.5 m tall. Trees are not present. Total vegetation cover is 30–65%, mean cover is 45.6%.

In this association, the shrub layer is characterized by *Opuntia littoralis, Rhus integrifolia,* and *Eriogonum cinereum. Artemisia californica, Yucca whipplei,* and *Encelia californica* are often included in this layer. The tree layer is absent. The herbaceous layer is simple and sometimes includes *Brassica nigra, Pennisetum setaceum, Bromus madritensis, Nassella lepida, Melica imperfecta, Calystegia macrostegia,* and *Foeniculum vulgare.*

Comments:
This association has similarities with the *Opuntia* spp.-Mixed Coastal Sage Scrub Shrubland Association stands in the study area. However, the cover of *Rhus integrifolia* is much higher, and the general aspect is low elevation on rockier slopes than the *Opuntia* Alliance stands. Stands may often be seen proximate to one another with the *R. integrifolia* Alliance almost always on the steeper and rockier portions of the slope.

Rhus ovata Shrubland Association

Sugar Bush Shrubland Association
***Rhus ovata* Shrubland Alliance**
Sugar Bush Shrubland Alliance

Mapping Code: 2193

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southwest- and northwest-facing slopes at low elevations between 194–520 m. It is characterized by a strong dominance of *Rhus ovata* in the shrub layer. The herbaceous layer is generally open with a varying mixture of native and nonnative species. The emergent tree layer includes *Quercus agrifolia* and *Juglans californica* but is usually absent.

Distribution:
This association is sampled in the Dry Inland, Immediate Coast, Eastern Urban, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 194–520 m, mean 339.8 m
Aspect: southwest and northwest
Slope: range 15–38 degrees, mean 29.3 degrees
Topography (micro; macro): flat, convex, or concave; middle slope
Litter Cover: range 10–70%, mean 40%
Small Rock Cover: range 3–44%, mean 23.5%
Large Rock Cover: range 0–1%, mean 0.5%
Bare Ground: range 27–40%, mean 33.5%
Parent Material: sedimentary
Soil Texture: fine clay

Vegetation Description:
Stands of *Rhus ovata* Shrubland form an open to intermittent shrub layer (8–62%, mean 41.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–17%, mean 4.3%) at 0–1 m tall. Trees are occasionally emergent (0–14% cover, mean 1.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 25–67%, mean cover is 47.7%.

In this association, the shrub layer is characterized by *Rhus ovata. Malacothamnus fasciculatus*, *Salvia mellifera, Heteromeles arbutifolia,* and *Malosma laurina* are occasionally included in this layer. The tree layer is emergent and open and infrequently includes *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Brassica nigra*, *Centaurea melitensis, Hirschfeldia incana,* and *Leymus condensatus.*

Other Noteworthy Species:
Astragalus brauntonii was found in 1 of 10 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 3-3-3. Global rank is G2, and state rank is S2.1 (CNPS 2005). Federal listing is Endangered, and state listing is none (SAMO 2004).

Juglans californica was found in 2 of 10 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Brassica nigra, Centaurea melitensis, Hirschfeldia incana, Bromus diandrus, Bromus madritensis, Marrubium vulgare, Erodium, Melilotus indicus

Samples Used in Description: (n = 10)
AA0126cc, rap0930m, rap1713, rap1871, rap1881, rap2015, rap2381, rap2574, rap2645, rap2729

Comments:
Some of the stands sampled in this association tend to be composed of hybrid backcrosses between *R. ovata* and *R. integrifolia*. However, the majority of physical characteristics of these shrubs appear to have more affinity to *R. ovata* than *R. integrifolia*.

Other stands of the *Rhus ovata* Alliance described from southern California tend to occur in the driy, inland portions of the region. This also appears to be the case in the Santa Monica Mountains area. Most stands of this association are found in the interior of the study area where summer temperatures are relatively hot and summer fog influence is minimal. Colder winter temperatures may also play a role in the distribution of this type by excluding *Malosma laurina*.

Phases:
None

Rhus ovata-Salvia leucophylla-Artemisia californica Shrubland Association

Sugar Bush-Purple Sage-California Sagebrush Shrubland Association
***Rhus ovata* Shrubland Alliance**
Sugar Bush Shrubland Alliance

Mapping Code: 2192

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northwest- and northeast-facing slopes at low elevations between 265–539 m. It is characterized by a codominance of *Rhus ovata, Salvia leucophylla,* and *Artemisia californica* in the shrub layer. The herbaceous layer often includes *Leymus condensatus.* The emergent tree layer includes occasional *Juglans californica* and *Quercus agrifolia*.

Distribution:
This association is sampled in the Dry Inland, Simi Hills Inland, Lower Elevation Inland Santa Monica Mountains, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 265–539 m, mean 373 m
Aspect: northwest and northeast
Slope: range 15—5 degrees, mean 33 degrees
Topography (micro; macro): undulating, flat, or convex; lower to upper slope
Litter Cover: no data
Small Rock Cover: 30%
Large Rock Cover: no data
Bare Ground: range 15–15%, mean 15%
Parent Material: sedimentary
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Rhus ovata-Salvia leucophylla-Artemisia californica* Shrubland form an intermittent to continuous shrub layer (38–62%, mean 45.5%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–6%, mean 1.7%) at 0–2 m tall. Trees are occasionally emergent (0–11% cover, mean 1.9%) with hardwoods at 0–10 m tall. Total vegetation cover is 41–68%, mean cover is 49.4%.

In this association, the shrub layer is characterized by *Rhus ovata, Salvia leucophylla*, *Artemisia californica,* and *Malacothamnus fasciculatus. Heteromeles arbutifolia, Malosma laurina*, *Eriogonum cinereum,* and *Salvia mellifera* are occasionally included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and frequently includes *Leymus condensatus. Centaurea melitensis* is also sometimes present.

Comments:
As with the other association of the *Rhus ovata* Alliance, this association occurs in the more inland portions of the Santa Monica Mountians study area. This type may predominate in areas that experience relatively severe winter frosts. Stands of this association differ from the previous association in having a shorter shrub layer of *Artemisia californica* and *Salvia leucophylla* that codominates with the taller and broader evergreen *Rhus ovata*. As with the previous type, *R. ovata* individuals in these stands also occasionally have characteristics morphologically intermediate between *R. ovata* and *R. integrifolia*.

Salix exigua Shrubland Alliance

Narrow Leaf Willow Shrubland Alliance

Mapping Code: 3110

Local Description

Summary:
This shrubland alliance usually occurs on flat or gentle sloping surfaces with little or no exposure at low elevations between 1 and 10 m. It is dominated by *Salix exigua* in the shrub layer. Other *Salix* species may be present at low cover including *S. lasiolepis.* The herbaceous layer is diverse and includes *Typha* sp., *Arundo donax*, *Melilotus albus*, and *Rorippa nasturtium-aquaticum* at low cover.

Distribution:
This alliance is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: range 1–10 m, mean 5.5 m
Aspect: none (flat)
Slope: range 0–2 degrees, mean 1.0 degrees
Topography (micro; macro): concave or flat; bottom
Litter Cover: no data
Small Rock Cover: range 0–20%, mean 10.0%
Large Rock Cover: range 0–10%, mean 5.0%
Bare Ground: range 60–80%, mean 70.0%
Parent Material: depositional
Soil Texture: sand (class unknown)

Vegetation Description:
Stands of the *Salix exigua* Shrubland Alliance form an open shrub layer (6–11%, mean 8.5%) at 0–2 m tall, an open tree layer (<0.2%) with hardwoods at 0–5 m tall, and an open herbaceous layer (4–5%, mean 4.5%) at 1–2 m tall. Total vegetation cover is 10–15%, mean cover is 12.5%.

In this alliance, the shrub layer is dominated by *Salix exigua*. Other *Salix* species may be present at relatively low cover including *S. lasiolepis.* The herbaceous layer is diverse and includes *Typha* sp., *Arundo donax*, *Melilotus albus*, and *Rorippa nasturtium-aquaticum* at low cover.

Samples Used in Description: (n = 2)
rap1127, rap1753

Comments:
This alliance is sparingly represented in the Santa Monica Mountains by small stands along permanent or intermittent streams. Most stands are small (< 0.5 ha).

Phases:
None

COMMON NAME Narrow Leaf Willow Alliance
SYNONYM Sandbar Willow, Coyote Willow

PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.B. Deciduous shrubland
PHYSIOGNOMIC GROUP	III.B.2. Cold-deciduous shrubland
PHYSIOGNOMIC SUBGROUP	III.B.2.N. Natural/Seminatural cold-deciduous shrubland
FORMATION	III.B.2.N.d. Temporarily flooded cold-deciduous shrubland
ALLIANCE	*Salix exigua* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5 (alliance)

Global Description

Distribution:
This alliance is widely known from much of North America. The related *Salix exigua* seasonally flooded woodland *a*lliance is only known from Texas and is considered a woodland, not a shrubland.

Nations:
United States, Canada

States or Provinces:
USA: AR, AZ, CA, CO, IA, ID, IL, IN, KS, KY?, MT, ND, NE, NM, NV, OH?, OK, OR, PA?, SD, TN?, TX, UT, WA, WY
CAN: MB, ON

Environmental Description:
Plant associations within this alliance are located on floodplains and gravel bars at an elevation range between 780 and 1,760 m in the West and at lower elevations (to below 100 m) in the midwestern and southeastern United States. These shrublands are found on open sandbars without canopy shading on larger, well-developed drainages and along larger sandy rivers or on coarser-textured substrates. They are associated with annual flooding and inundation and will grow well into the channel, where it is flooded, even in drier years. Even though flooding is frequent, surface water is not present for much of the growing season and the water table is well below the surface. Some stands form large, wide stands on midchannel islands on larger rivers or narrow stringer bands on small, rocky tributaries. Stream reaches range widely from moderately sinuous and moderate-gradient reaches to broad, meandering rivers with wide floodplains or broad, braided channels. Many stands also occur within highly entrenched or eroding gullies.

This alliance represents an early seral primary successional stage on newly deposited sediments that may persist under a regime of repeated fluvial disturbance. *Salix exigua* and *Salix interior* are highly adapted to most forms of disturbance. Both species are prolific sprouters and will reestablish themselves on sites dominated by other disturbance-associated species, for example, *Glycyrrhiza lepidota* and *Pascopyrum smithii*.

Vegetation Description:
Plant associations within this alliance are characterized as temporarily flooded cold-deciduous shrubland dominated by *Salix exigua* or *Salix interior*. The tall shrub layer has 15–90% cover, ranging in height between 2–5 m. Other willows can occur in the canopy including *Salix eriocephala, Salix lutea, Salix ligulifolia,* and *Salix monticola*. Occasionally the taller *Salix amygdaloides* or *Populus deltoides* occur within the tree subcanopy. The herbaceous layer varies greatly over the broad range of the alliance. It has at least 20–35% cover of various graminoid species including *Carex nebrascensis, Carex pellita (Carex lanuginosa), Spartina pectinata, Phalaris arundinacea, Equisetum arvense, Panicum bulbosum*, and *Muhlenbergia rigens.* The forb cover is usually sparse. The understory can be dominated by barren ground or gravel bar. In Oklahoma, some associates can include *Cephalanthus occidentalis, Eupatorium serotinum, Panicum virgatum, Parthenocissus quinquefolia, Pluchea odorata, Tamarix chinensis*, and *Vitis acerifolia* (Hoagland 2000).

Comments:
All stands of this alliance seen in California are shrublands, though they may be taller than 5 m.

Salvia leucophylla Shrubland Association

Purple Sage Shrubland Association
***Salvia leucophylla* Shrubland Alliance**
Purple Sage Shrubland Alliance

Mapping Code: 3316

Local Description

Summary:
This shrubland association occurs on gentle to very steep slopes of variable aspect at low elevations between 18–613 m. It is characterized by a strong dominance of *Salvia leucophylla* in the shrub layer. The herbaceous layer is composed of both native and nonnative grasses and herbs. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, Immediate Coast, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 18–613 m, mean 331 m
Aspect: variable
Slope: range 2–50 degrees, mean 25.5 degrees
Topography (micro; macro): convex, undulating, flat, or concave; bottom to ridgetop
Litter Cover: range 15–75%, mean 33.6%
Small Rock Cover: range 0–60%, mean 13.6%
Large Rock Cover: range 0–8%, mean 0.7%
Bare Ground: range 10–90%, mean 37.4%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam to fine clay

Vegetation Description:
Stands of *Salvia leucophylla* Shrubland form an open to intermittent shrub layer (12–60%, mean 35.5%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to intermittent (0–43%, mean 6.6%) at 0–2 m tall. Trees are occasionally emergent (0–9% cover, mean 0.8%) with conifers at 0–15 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 23–65%, mean cover is 42.8%.

In this association, the shrub layer is characterized by *Salvia leucophylla* and *Artemisia californica. Malacothamnus fasciculatus* is often included in this layer. Other shrubs sometimes found include *Malosma laurina, Sambucus mexicana, Baccharis pilularis*, *Hazardia squarrosa, Rhus ovata,* and *Eriogonum cinereum*. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Brassica nigra, Leymus condensatus,* and *Centaurea melitensis.*

Comments:
This is a characteristic and common alliance of the coastal sage scrub in the Santa Monica Mountains study area. It is clearly related to other alliances, particularly the *Artemisia californica* Alliance. However, as shown in a Bray-Curtis ordination (McCune and Grace 2002), samples of the full array of stands dominated or codominated by *Artemisia californica* and/or *Salvia leucophylla* tend to segregate from stands dominated by *Artemisia,* while stands dominated by *S. leucophylla* or codominated by *S. leucophylla* and *A. californica* share the same ordination space. This suggests that any stand with either pure *S. leucophylla* or more or less equal mixes of the two shrubs should be considered in the *S. leucophylla* Alliance. As indicated by the list of phases, there is substantial variation in this association. Phases tend to represent seral stage (e.g., higher cover of short-lived perennials, such as *Malacothamnus fasciculatus*, or higher cover of perennial grasses that respond to burning such as *Leymus condensatus*). The presence of *Nassella* spp. in some stands may indicate a specific moisture regime coupled with soil texture (finer-grained clay-rich soils) that has yet to be fully defined. Further identification at the species level may indicate that most of the *Nassella* species are *Nassella lepida*, a common understory to more coastal (fog zone) stands of coastal sage scrub.

Phases:
Salvia leucophylla-Artemisia californica Malacothamnus fasciculatus (Purple Sage-California Sagebrush-Bush Mallow) Phase [8311]
Salvia leucophylla-Artemisia californica (Purple Sage-California Sagebrush) Phase [3316]
Salvia leucophylla/Leymus condensatus (Purple Sage/Giant Wild Rye) Phase [3319]
Salvia leucophylla/Nassella spp. (Purple Sage/Needlegrass) Phase [3311]

Salvia leucophylla-Artemisia californica Shrubland Association

Purple Sage-California Sagebrush Shrubland Association
***Salvia leucophylla* Shrubland Alliance**
Purple Sage Shrubland Alliance

Mapping Code: 3391

Local Description

Summary:
This shrubland association occurs on moderately steep to very steep northwest- and northeast-facing slopes at low elevations between 24–472 m. It is characterized by a codominance of *Artemisia californica* and *Salvia leucophylla* in the shrub layer with no distinguishing species in the herbaceous layer. The emergent tree layer is generally absent but can include *Quercus agrifolia, Q. lobata*, or *Juglans californica*.

Distribution:
This association is sampled in the Dry Inland, Simi Hills Inland, Immediate Coast, Western Fog Zone, Upper Elevation Santa Monica Mountains, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 24–472 m, mean 289.5 m
Aspect: northwest and northeast
Slope: range 10–46 degrees, mean 28.8 degrees
Topography (micro; macro): undulating, flat, concave, or convex; lower to upper slope
Litter Cover: range 15–45%, mean 28.9%
Small Rock Cover: range 1–57%, mean 15.2%
Large Rock Cover: range 0–10%, mean 1.2%
Bare Ground: range 2–65%, mean 33.9%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam to fine clay

Vegetation Description:
Stands of *Salvia leucophylla-Artemisia californica* Shrubland form an open to intermittent shrub layer (13–52%, mean 35.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–29%, mean 6.3%) at 0–2 m tall. Trees are occasionally emergent (0–15% cover, mean 1.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 24–65%, mean cover is 42.8%.

In this association, the shrub layer is characterized by *Salvia leucophylla* and *Artemisia californica. Malosma laurina, Malacothamnus fasciculatus,* and *Sambucus mexicana* are occasionally included in this layer. The tree layer is emergent and open and rarely includes *Quercus agrifolia, Juglans californica, and Quercus lobata* at low cover. The herbaceous layer is diverse and often includes *Leymus condensatus. Brassica nigra, Centaurea melitensis,* and *Bromus diandrus* are occasionally present in this layer.

Other Noteworthy Species:
Baccharis plummerae was found in 1 of 79 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-1-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Calochortus catalinae was found in 1 of 79 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Dichondra occidentalis was found in 1 of 79 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G4?, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 6 of 79 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Leptodactylon californicum was found in 1 of 79 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G5T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Stanleya pinnata was found in 1 of 79 surveys of this plant community. Regionally, the park considers this species as Locally Rare. CNPS ranks this species as List none, CNPS R-E-D Code is 0-0-0. Global rank is none, and state rank is none (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Brassica nigra, Centaurea melitensis, Bromus diandrus, Hirschfeldia incana, Bromus madritensis, Melilotus indicus, Avena fatua, Carduus pycnocephalus, Nicotiana glauca, Anagallis arvensis, Galium aparine, Schinus molle, Brassica, Erodium, Erodium cicutarium, Marrubium vulgare, Schinus molle, Senecio vulgaris, Silybum marianum, Sonchus

Comments:
This is an abundant and characteristic association within the study area. It has a range of expressions from intermittent to open cover and includes a variety of species that may be occasionally present. Either *Artemisia californica* or *Salvia leucophylla* may be more than twice the cover of the other species. Two phases exist based on these variations.

Phases:
Salvia leucophylla-Artemisia californica (California Sagebrush-Purple Sage codominance) Phase [3391]
Salvia leucophylla-Artemisia californica/Leymus condensatus (California Sagebrush-Purple Sage/Giant Wild Rye) Phase [3393]

COMMON NAME	Purple Sage-California Sagebrush Shrubland Association
SYNONYM	Purple Sage-California Sagebrush (Kirkpatrick and Hutchinson 1977), Ventura Coastal Sage Scrub (Holland 1986)
PHYSIOGNOMIC CLASS	III. Shrubland
PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic subdesert shrubland
ALLIANCE	*Salvia leucophylla* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association has been described from the Santa Monica Mountains and the northwestern peninsular ranges of Orange County (Gordon and White 1994). It is likely to occur farther north as far as San Luis Obispo County, but information about its global distribution is not available without additional inventory. In Los Padres National Forest, Borchert et al. 2004 have an analogous codominant vegetation type, which they interpret at the alliance level.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Although this is a very common association in the study area, its range is probably largely limited to the region between coastal Los Angeles and coastal San Luis Obispo counties. A similar association was described by Kirkpatrick and Hutchinson 1977. However, their definition was somewhat broader than this one.

Borchert et al. 2004, Gordon and White 1994, Holland 1986, Kirkpatrick and Hutchinson 1977

Salvia leucophylla-Artemisia californica-Eriogonum cinereum/Nassella spp. Shrubland Association

Purple Sage-California Sagebrush-Ashy Buckwheat/Needlegrass Shrubland Association
***Salvia leucophylla* Shrubland Alliance**
Purple Sage Shrubland Alliance

Mapping Code: 3396

Local Description

Summary:
This shrubland association occurs on gentle to steep northwest- and northeast-facing slopes at low elevations between 9–457 m. It is characterized by a codominance of *Artemisia californica* and *Salvia leucophylla* with a subdominance of *Eriogonum cinereum* in the shrub layer and a low cover of native grasses such as *Nassella lepida, Nassella* sp., and *Leymus condensatus* in the herbaceous layer. The emergent tree layer is generally absent.

Distribution:
This association is sampled in the Western Fog Zone, Immediate Coast, Dry Inland, Lower Elevation Inland Santa Monica Mountains, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 9–457 m, mean 198.7 m
Aspect: Variable, most often northwest and northeast
Slope: range 2–45 degrees, mean 22.5 degrees
Topography (micro; macro): flat, undulating, or convex; lower slope to ridgetop
Litter Cover: range 0–85%, mean 37.2%
Small Rock Cover: range 0–50%, mean 13.2%
Large Rock Cover: range 0–15%, mean 0.9%
Bare Ground: range 5–75%, mean 31%
Parent Material: sedimentary or quaternary
Soil Texture: moderately fine sandy clay loam to fine clay

Vegetation Description:
Stands of *Salvia leucophylla-Artemisia californica-Eriogonum cinereum/Nassella* spp. Shrubland form an open to intermittent shrub layer (9–59%, mean 32.2%). Shrubs occur in two different strata, with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open to intermittent (0–65%, mean 13.9%) at 0–1 m tall. Trees are occasionally emergent (0–4% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 16–90%, mean cover is 45.3%.

In this association, the shrub layer is characterized by *Artemisia californica, Salvia leucophylla,* and *Eriogonum cinereum. Malosma laurina*, *Hazardia squarrosa,* and *Lotus scoparius* are often included in this layer. The tree layer is emergent and open and infrequently includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and usually includes *Leymus condensatus,* while *Nassella lepida* and *Bromus madritensis* are sometimes present.

Comments:
Although similar to the *S. leucophylla-A. californica* Association of the same alliance, this association has a constant and significant cover of *Eriogonum cinereum*. This shrub is largely endemic to the greater Santa Monica Mountains area and tends to denote steep slopes within the coastal fog zone. Several phases have been identified depending on the relative cover and constancy of other associated shrubs. Although *Nassella lepida* appears to be the most common associated grass, some samples were taken when the species of *Nassella* was not positively identified—hence the addition of *Nassella* sp. in the species list. Postfire stands tend to have a relative increase in grasses and short-lived perennial shrubs such as *Nassella* spp. and *Hazardia squarrosa* or *Malacothamnus fasciculatus.* The coastal influence and steep slopes of this association are also underscored by the presence of *Rhus integrifolia* in 40% of the stands sampled. Additional phases have been identified with relatively higher cover and frequency of *Malosma laurina* and based on the addition of *Mimulus aurantiacus* to the constant mixture of the other species.

Phases:
Salvia leucophylla-Artemisia californica-Eriogonum cinereum/Nassella spp. (California Sagebrush-Purple Sage-Ashy Buckwheat/Needlegrass) Phase [3396]
Salvia leucophylla-Artemisia californica-Malosma laurina/Nassella spp. (California Sagebrush-Purple Sage-Laurel Sumac/Needlegrass) Phase [3395]
Salvia leucophylla-Artemisia californica-Mimulus aurantiacus (California Sagebrush-Purple Sage-Bush Monkey Flower) Phase [3392]

COMMON NAME	Purple Sage-California Sagebrush-Ashy Buckwheat/Needlegrass Shrubland Association
SYNONYM	None
PHYSIOGNOMIC CLASS	III. Shrubland

ALLIANCE	*Salvia leucophylla* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. In the Los Padres National Forest, Borchert et al. 2004 have an analogous codominant alliance, reinterpreted by Sawyer et al. 2006.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
The range of *Eriogonum cinereum* extends from Los Angeles to Santa Barbara counties with its center of distribution in the Santa Monica Mountains.

Salvia leucophylla-Eriogonum cinereum/Annual Grass-Herb Shrubland Association

Purple Sage-Ashy Buckwheat/Annual Grass-Herb Shrubland Association
***Salvia leucophylla* Shrubland Alliance**
Purple Sage Shrubland Alliance

Mapping Code: 3312

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southeast- and southwest-facing slopes at low elevations between 0–494 m. It is characterized by dominance to codominance of *Salvia leucophylla* with subdominance to codominance of *Eriogonum cinereum* in the shrub layer.

Distribution:
This association is sampled in the Dry Inland, Immediate Coast, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–494 m, mean 272.4 m
Aspect: southeast and southwest
Slope: range 15–38 degrees, mean 27.7 degrees
Topography (micro; macro): undulating or convex; lower slope to ridgetop
Litter Cover: range 15–45%, mean 26.7%
Small Rock Cover: range 5–50%, mean 19.7%
Large Rock Cover: range 0–2%, mean 0.2%
Bare Ground: range 15–62%, mean 38.7%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Salvia leucophylla-Eriogonum cinereum/*Annual Grass-Herb Shrubland form an open to intermittent shrub layer (20–48%, mean 32.6%). Shrubs occur in two different strata with low shrubs at 0–1 m tall and tall shrubs at 1–2 m tall. The herbaceous layer is open (0–23%, mean 6.9%) at 0–1 m tall. Trees are not present. Total vegetation cover is 30–55%, mean cover is 39.3%.

In this association, the shrub layer is characterized by *Eriogonum cinereum, Salvia leucophylla,* and *Artemisia californica*. *Yucca whipplei* and *Encelia californica* are often included in this layer. The tree layer is absent. The herbaceous layer is simple and often includes *Brassica nigra* and *Leymus condensatus.* Other herbs sometimes present include *Centaurea melitensis, Hirschfeldia incana, Bromus madritensis,* and *Bromus diandrus.*

Salvia mellifera Shrubland Association

Black Sage Shrubland Association
***Salvia mellifera* Shrubland Alliance**
Black Sage Shrubland Alliance

Mapping Code: 3324

Local Description

Summary:
This shrubland association occurs on moderate to very steep southeast- and southwest-facing slopes at low elevations between 20–768 m. It is characterized by a strong dominance of *Salvia mellifera* in the shrub layer. The herbaceous layer is generally insignificant, as is the emergent tree layer.

Distribution:
This association is sampled in the Dry Inland, Western Fog Zone, Upper Elevation Santa Monica Mountains, Simi Hills Inland, Eastern Urban, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 20–768 m, mean 332.8 m
Aspect: southeast and southwest
Slope: range 10–46 degrees, mean 29.4 degrees
Topography (micro; macro): undulating, convex, or flat; lower slope to ridgetop
Litter Cover: range 15–70%, mean 34.1%
Small Rock Cover: range 0–40%, mean 18.1%
Large Rock Cover: range 0–25%, mean 2%
Bare Ground: range 0–55%, mean 32.9%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine to fine clay loam

Vegetation Description:
Stands of *Salvia mellifera* Shrubland form an open to intermittent shrub layer (21–55%, mean 36.4%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–19%, mean 2.2%) at 0–1 m tall. Trees are occasionally emergent (0–8% cover, mean 0.3%) with hardwoods at 0–10 m tall. Total vegetation cover is 21–55%, mean cover is 38.7%.

In this association, the shrub layer is characterized by abundant *Salvia mellifera. Yucca whipplei*, *Adenostoma fasciculatum,* and *Artemisia californica* are often included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica, Quercus agrifolia,* and *Schinus molle* at low cover. The herbaceous layer is diverse and sometimes includes *Bromus madritensis*, *Centaurea melitensis,* and *Brassica nigra*. Other herbs present may include *Hirschfeldia incana, Leymus condensatus, Melica imperfecta,* and *Nassella lepida*.

Comments:
This is a common association in the study area. It is physiognomically part of the coastal sage scrub vegetation formation, but ecologically, *Salvia mellifera* is often associated with certain chaparrals such as *Adenostoma fasciculatum* and *Adenostoma fasciculatum-Salvia mellifera* alliances. *S. mellifera* is more completely drought deciduous than some other species of the coastal sage scrub, and this may enable it to tolerate extremely hot and dry exposures often found in the xeric chaparrals. The phases identified in this association reflect a pure form with monospecific dominance, a postfire form with bush mallow, a mixed xeric scrub with California buckwheat, and a transition to more of chaparral vegetation.

Phases:
Salvia mellifera-Malacothamnus fasciculatus (Black Sage-Bush Mallow) Phase [3322]
Salvia mellifera-Eriogonum fasciculatum (Black Sage-California Buckwheat) Phase [3321]
Salvia mellifera (Black Sage) Phase [3324]
Salvia mellifera-Adenostoma fasciculatum (Black Sage-Chamise) Phase [3329]

COMMON NAME	Black Sage Shrubland Association

PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Salvia mellifera* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S4

Global Description

Distribution:
This association is known from the Santa Monica Mountains and other portions of the western transverse ranges (Malanson 1984) and probably in coastal ranges of California from the central portion of the state (Evens and San 2004) to at least the Mexican border. It is likely that some of the stands sampled by Borchert et al. 2004 on the Los Padres National Forest of Ventura, Santa Barbara, and San Luis Obispo counties can be placed in this association. This association has also been described from San Diego County and Orange County (Desimone and Burk 1992) and may occur as far north as Contra Costa County (Ertter and Bowerman 2002).

Nations:
United States

States or Provinces:
CA

Environmental Description:
Information from Borchert et al. 2004, Klein and Evens 2005, and Evens and San 2005 suggests that the elevation range of this association extends upward to 1,050 m in places like Riverside

County, apparently in drier and more inland south coastal areas with aspect tending to face more northeast than in the Santa Monica Mountains (Klein and Evens 2005).

Vegetation Description:
Based on the description of this association from Riverside County (Klein and Evens 2005) and San Diego County (Evens and San 2005), we can add the following information:
Salvia mellifera is usually the dominant shrub in the overstory. *Eriogonum fasciculatum* is consistently present, usually as a subdominant shrub. A variety of other coastal sage and chaparral species frequently intermix in the shrub layer as subdominants. Some of these species include *Artemisia californica*, *Ceanothus crassifolius*, *Adenostoma fasciculatum*, *Keckiella antirrhinoides*, and *Encelia farinosa*. The understory herbaceous layer consists of native species, such as *Leymus condensatus* and *Nassella lepida,* and nonnative species such as *Bromus madritensis* and *Centaurea melitensis*.

Comments:
See local description.

Borchert et al. 2004, Desimone and Burk 1992, Ertter and Bowerman 2002, Evens and San 2004, Evens and San 2005, Klein and Evens 2005, Malanson 1984

Salvia mellifera-Eriogonum cinereum Shrubland Association

Black Sage-Ashy Buckwheat Shrubland Association
***Salvia mellifera* Shrubland Alliance**
Black Sage Shrubland Alliance

Mapping Code: 3323

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep southwest-facing slopes at low elevations between 0–507 m. It is characterized by a dominance of *Salvia mellifera* and a subdominance of *Eriogonum cinereum* in the shrub layer. Herbs and trees are insignificant in this association.

Distribution:
This association is sampled in the Western Fog Zone, Dry Inland, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 0–507 m, mean 186.9 m
Aspect: southwest
Slope: range 15–40 degrees, mean 32.8 degrees
Topography (micro; macro): undulating, flat, or convex; lower to upper slope
Litter Cover: range 15–20%, mean 17.5%
Small Rock Cover: range 5–40%, mean 16.6%
Large Rock Cover: range 0–10%, mean 2.1%
Bare Ground: range 10–70%, mean 39.6%
Parent Material: igneous
Soil Texture: coarse loamy sand to moderately fine clay loam

Vegetation Description:
Stands of *Salvia mellifera-Eriogonum cinereum* Shrubland form an open to intermittent shrub layer (21–45%, mean 33.9%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–9%, mean 1.6%) at 0–1 m tall. Trees are occasionally emergent (0–8% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 25–50%, mean cover is 35.9%.

In this association, the shrub layer is characterized by *Salvia mellifera, Eriogonum cinereum*, *Malosma laurina,* and *Yucca whipplei*. *Rhus ovata* and *Encelia californica* are often included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Centaurea melitensis* and *Leymus condensatus.* Other herbs may include *Calystegia macrostegia*, *Hirschfeldia incana*, *Bromus madritensis,* and *Cuscuta californica*.

Other Noteworthy Species:
Erysimum insulare was found in 1 of 20 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Avena, Hirschfeldia incana, Pennisetum setaceum, Bromus madritensis, Spartium junceum, Avena fatua, Brassica nigra

Samples Used in Description: (n = 20)
AA0326cc, AA0778, AA0828, AA0959, rap0016m, rap0064, rap0108, rap0109m, rap0115, rap0116, rap0117, rap1469m, rap1479, rap1723, rap1861, rap1863, rap1925m, rap1961, rap2602, rap2728

Comments:
This association is likely to be endemic to the western transverse ranges, primarily centered on the Santa Monica Mountains area. This association may be found on steep south-facing slopes often within the belt of summer fog and, thus, typically at lower elevation and more coastal settings than other associations of the *Salvia mellifera* Alliance.

Phases:
None

Salvia mellifera-Malosma laurina Shrubland Association

Black Sage-Laurel Sumac Shrubland Association
***Salvia mellifera* Shrubland Alliance**
Black Sage Shrubland Alliance

Mapping Code: 8324

Local Description

Summary:
This shrubland association occurs on gentle to steep southeast and southwest-facing slopes at low elevations between 20–485 m. It is characterized by a dominance of *Salvia mellifera* and a subdominance of *Malosma laurina* in the shrub layer. The herbaceous layer and emergent tree layer are insignificant.

Distribution:
This association is sampled in the Immediate Coast, Western Fog Zone, Lower Elevation Inland Santa Monica Mountains, Eastern Urban Upper Elevation Santa Monica Mountains, Dry Inland, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 20–485 m, mean 155.6 m
Aspect: southeast and southwest
Slope: range 3–45 degrees, mean 27.1 degrees
Topography (micro; macro): variable (all); bottom to top
Litter Cover: range 7–55%, mean 23.3%
Small Rock Cover: range 2–50%, mean 23.6%
Large Rock Cover: range 0–8%, mean 1.3%
Bare Ground: range 15–80%, mean 37.1%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine to fine clay loam

Vegetation Description:
Stands of *Salvia mellifera-Malosma laurina* Shrubland form an open to intermittent shrub layer (22–58%, mean 36.1%). Shrubs occur in two different strata with low shrubs at 0–20 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–15%, mean 3.4%) at 0–2 m tall. Trees are occasionally emergent (0–9% cover, mean 0.3%) with hardwoods at 0–15 m tall. Total vegetation cover is 25–60%, mean cover is 39.6%.

In this association, the shrub layer is characterized by *Salvia mellifera, Malosma laurina,* and *Artemisia californica. Yucca whipplei, Encelia californica, Eriogonum cinereum,* and *Rhus integrifolia* are usually included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* and *Juglans californica* at low cover. The herbaceous layer is diverse and sometimes includes *Nassella lepida* and *Bromus madritensis.* Other herbs present may include *Leymus condensatus, Brassica nigra,* and *Nassella pulchra*.

Comments:
This is the most widespread association of the *Salvia mellifera* Alliance expressed locally. *Malosma laurina* is a large shrub and appears as an emergent over the shorter drought deciduous *S. mellifera* in mature stands. Both of the main species in this association tolerate summer drought using different strategies—the shallow-rooted *S. mellifera* by dropping most of its leaves and the deep-rooted *Malosma* by tapping into moisture deep in the substrate. A phase of this association is found on steep coastward slopes and includes the presence of *Rhus integrifolia* as well as the other two main species**.**

Phases:
Salvia mellifera-Artemisia californica-Rhus integrifolia (Black Sage-California Sagebrush-Lemonade Berry) Phase [8322]
Salvia mellifera-Malosma laurina (Black Sage-Laurel Sumac) Phase [8324]

Salvia mellifera-Rhus ovata Shrubland Association

Black Sage-Sugar Bush Shrubland Association
***Salvia mellifera* Shrubland Alliance**
Black Sage Shrubland Alliance

Mapping Code: 8325

Local Description

Summary:
This shrubland association occurs on gentle to steep northeast- and southeast-facing slopes at low elevations between 140–618 m. It is characterized by dominance of *Salvia mellifera* and subdominance of *Rhus ovata* in the shrub layer. The herbaceous and tree layers are insignificant.

Distribution:
This association is sampled in the Eastern Urban, Simi Hills Inland, Dry Inland, Upper Elevation Santa Monica Mountains, Lower Elevation Inland Santa Monica Mountains, Western Fog Zone, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 140–618 m, mean 325.2 m
Aspect: northeast and southeast
Slope: range 2–40 degrees, mean 29.4 degrees
Topography (micro; macro): undulating, convex, or flat; lower slope to ridgetop
Litter Cover: range 15–50%, mean 30.6%
Small Rock Cover: range 8–25%, mean 16.7%
Large Rock Cover: range 0–25%, mean 3.7%
Bare Ground: range 15–55%, mean 41.4%
Parent Material: sedimentary or igneous
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Salvia mellifera-Rhus ovata* Shrubland form an open to intermittent shrub layer (26–47%, mean 35.6%). Shrubs occur in two different strata, with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–15%, mean 4.2%) at 0–1 m tall. Trees are occasionally emergent (0–4% cover, mean 0.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 31–51%, mean cover is 40.4%.

In this association, the shrub layer is characterized by *Salvia mellifera* and *Rhus ovata. Artemisia californica, Heteromeles arbutifolia,* and *Malosma laurina* are often included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and sometimes includes *Centaurea melitensis, Leymus condensatus,* and *Hirschfeldia incana*.

Other Noteworthy Species:
Juglans californica was found in 2 of 19 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Centaurea melitensis, Hirschfeldia incana, Acacia redolens, Bromus hordeaceus, Bromus madritensis, Bromus diandrus, Brassica nigra, Nicotiana glauca, Piptatherum miliaceum

Samples Used in Description: (n = 19)
AA0169cc, AA0341, AA0395cc, AA0442cc, AA0459cc, AA0603, AA0740cc, AA0817, AA1098, rap0890, rap1477, rap1808, rap1809, rap2090, rap2313, rap2501, rap2564, rap2575, rap2688

Comments:
This association is primarily found in the warmer inland portions of the study area. Slopes tend to be facing cooler, shadier directions than in other *Salvia mellifera* Associations locally; however, slopes are still relatively steep. The presence of *Heteromeles arbutifolia* or *Ceanothus spinosus* in many stands also suggests a slightly more mesic setting than other *S. mellifera* associations. High frost frequency may play a role in favoring *R. ovata* over *M. laurina* in these stands.

Phases:
None

COMMON NAME Black Sage-Sugar Bush Shrubland Association
SYNONYM None
PHYSIOGNOMIC CLASS III. Shrubland

PHYSIOGNOMIC SUBCLASS	III.A. Evergreen shrubland
PHYSIOGNOMIC GROUP	III.A.5. Extremely xeromorphic evergreen shrubland
PHYSIOGNOMIC SUBGROUP	III.A.5.N. Natural/Seminatural
FORMATION	III.A.5.N.b. Facultatively deciduous, extremely xeromorphic
ALLIANCE	*Salvia mellifera* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3?

Global Description

Distribution:
This association is known from the Santa Monica Mountains and western Riverside County (Klein and Evens 2005). Information about its global distribution is not available without additional inventory but is likely to include much of interior south coastal California inland from the immediate coast.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
Samples from western Riverside County (Klein and Evens 2005) add the following information: In the *Salvia mellifera-Rhus ovata* Association, *Rhus ovata* is consistently present as a codominant or subdominant shrub. *Eriogonum fasciculatum*, *Artemisia californica*, *Encelia farinosa*, *Adenostoma fasciculatum,* and *Ceanothus crassifolius* are occasionally to often present as subdominant shrubs.

Comments:
Heteromeles arbutifolia is a less common associate of this type in western Riverside County than in the Santa Monica Mountains.

Klein and Evens 2005

Salvia mellifera-Artemisia californica Shrubland Association

Black Sage-California Sagebrush Shrubland Association
***Salvia mellifera-Artemisia californica* Shrubland Alliance**
Black Sage-California Sagebrush Shrubland Alliance

Mapping Code: 3421

Local Description

Summary:
This shrubland association occurs on moderate to steep slopes of variable aspect at low elevations between 0–415 m. It is characterized by a codominance of *Salvia mellifera* and *Artemisia californica* in the shrub layer. The herbaceous layer is composed of a variety of mostly nonnative species at low cover. The emergent tree layer includes occasional *Quercus agrifolia*.

Distribution:
This association is sampled in the Western Fog Zone, Dry Inland, Immediate Coast, Eastern Urban, Lower Elevation Inland Santa Monica Mountains, Simi Hills Inland, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 0–415 m, mean 231.7 m
Aspect: variable
Slope: range 14–36 degrees, mean 24 degrees
Topography (micro; macro): undulating, flat, or convex; lower slope to ridgetop
Litter Cover: range 25–45%, mean 32.5%
Small Rock Cover: range 2–30%, mean 12.7%
Large Rock Cover: range 0–5%, mean 2%
Bare Ground: range 15–53%, mean 36.2%
Parent Material: sedimentary or igneous
Soil Texture: coarse to very fine loamy sand

Vegetation Description:
Stands of *Salvia mellifera-Artemisia californica* Shrubland form an open to intermittent shrub layer (31–45%, mean 39.2%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 0.5–5 m tall. The herbaceous layer is open (0–13%, mean 3.2%) at 0–1 m tall. Trees are occasionally emergent (0–2% cover, mean 0.3%) with hardwoods at 0–10 m tall. Total vegetation cover is 34–55%, mean cover is 42.8%.

In this association, the shrub layer is characterized by *Artemisia californica* and *Salvia mellifera*. *Malosma laurina* and *Adenostoma fasciculatum* are often included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia* at low cover. The herbaceous layer is simple and often includes *Hirschfeldia incana*. Other herbs present may include *Melica imperfecta, Bromus madritensis*, *Leymus condensatus,* and *Calystegia macrostegia*.

AA0254cc, AA0420, AA0860, AA0912, rap0297, rap1720, rap1755, rap2072, rap2481, rap2907rlv

Comments:
This is a relatively uncommon association in the study area. Since sampling in these facultatively drought deciduous shrublands occurred throughout much of the year, the variance of total cover and individual species cover is expected to be high. The *S. mellifera* association of the same alliance can be differentiated from this association by its monospecific dominance of black sage.

Phases:
None

***Sambucus mexicana* Shrubland Alliance**
Mexican Elderberry Shrubland Alliance

Mapping Code: 3021

Local Description

Summary:
This shrubland association occurs on gentle to steep northeast- and northwest-facing slopes at low elevations between 0–511 m. It is characterized by dominance in the shrub layer or the low tree layer of *Sambucus mexicana* and relatively high cover of the grass *Leymus condensatus* in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia* and *Juglans californica*.

Distribution:
This association is sampled in the Dry Inland, Eastern Urban, Immediate Coast, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 0–511 m, mean 270.2 m
Aspect: northeast and northwest
Slope: range 2–35 degrees, mean 18.6 degrees
Topography (micro; macro): undulating, concave, or flat; bottom to middle slope
Litter Cover: range 45–85%, mean 66.7%
Small Rock Cover: range 0–10%, mean 3.4%
Large Rock Cover: no data
Bare Ground: range 10–40%, mean 24.2%
Parent Material: sedimentary
Soil Texture: moderately fine clay loam

Vegetation Description:
Stands of *Sambucus mexicana/Leymus condensatus-Annual Grass-Herb* Shrubland form an open to intermittent shrub layer (0–51%, mean 16.1%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open to intermittent (11–57%, mean 29.7%) at 0–1 m tall. Trees are occasionally emergent (0–27% cover, mean 12.4%) with hardwoods at 0–10 m tall. Total vegetation cover is 46–70%, mean cover is 57.4%.

In this association, the shrub layer often includes *Sambucus mexicana, Baccharis pilularis,* and *Artemisia californica. Malosma laurina, Hazardia squarrosa,* and *Nicotiana glauca* are sometimes included in this layer. The tree layer is emergent and open and may infrequently include *Quercus agrifolia*, *Juglans californica,* and *Schinus molle* at low cover. The herbaceous layer is simple and is characterized by *Leymus condensatus* and *Brassica nigra*. Other herbs sometimes include *Bromus diandrus, Marah macrocarpus, Centaurea melitensis*, *Conium maculatum,* and *Bromus madritensis.*

rap0843, rap0978, rap1132, rap1852, rap2022, rap2177m, rap2363, rap2568, rap2651

Comments:
This association is found scattered throughout the study area usually in mesic settings. The settings seem to reflect some level of past disturbance from fire or nonnatural clearing and suggest in some cases the removal of higher cover of trees or coastal scrub species recently. Some natural stands are semiriparian. The relatively low constancy values for *Sambucus mexicana* in either the tree or the shrub layer do not reflect the absence of the species in some stands. Taken cumulatively, *S. mexicana* either as a shrub or a small tree is present in all of the stands.

Phases:
None

COMMON NAME	Mexican Elderberry/Giant Wild Rye-Annual Herb Shrubland Association
SYNONYM	None
FORMATION CLASS	III. Shrubland
FORMATION SUBCLASS	III.B. Deciduous shrubland
Formation Group	III.B.2. Cold-deciduous shrubland
FORMATION SUBGROUP	III.B.2.N. Natural/Seminatural cold-deciduous shrubland

ALLIANCE	*Sambucus mexicana* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3?

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. Similar, though probably not identical, stands occur in the California coast ranges as far north as Marin County (Keeler-Wolf et al. 2003) and south to San Diego County (Evens and San 2005). Holland 1986 describes an elderberry savanna from the Central Valley.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Scattered stands of *Sambucus mexicana* occur throughout much of cismontane California but have not been well sampled. Contradictory to the formal hierarchy above, many stands are not intermittently flooded, at least not in the urban portions of Santa Monica Mountains study area.

Sambucus mexicana-Heteromeles arbutifolia/Annual Grass-Herb Shrubland Association

Mexican Elderberry-Toyon/Annual Grass-Herb Shrubland Association
***Sambucus mexicana* Shrubland Alliance**
Mexican Elderberry Shrubland Alliance

Mapping Code: 3022

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep usually north-facing slopes at low elevations between 261–420 m. It is dominated by *Sambucus mexicana* and secondarily by *Heteromeles arbutifolia* in the shrub layer. The herbaceous layer is diverse, with *Leymus condensatus* often present at low to moderate cover. Other herbs are occasionally present such as *Bromus, Marah macrocarpus, Cortaderia,* and *Cuscuta californica*. The tree layer is occasionally present with species such as *Quercus agrifolia* and/or *Juglans californica.*

Distribution:
This association is sampled in the Eastern Urban, Immediate Coast, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 261–420 m, mean 331.4 m
Aspect: frequently northwest or northeast, rarely southwest or variable
Slope: range 15–38 degrees, mean 31.6 degrees
Topography (micro; macro): often undulating or convex; often mid to upper slopes, sometimes to bottom or ridgetop
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: frequently sedimentary, sometimes depositional or igneous
Soil Texture: no data

Vegetation Description:
Stands of *Sambucus mexicana-Heteromeles arbutifolia*/Annual Grass-Herb Shrubland form an open to intermittent shrub layer (19–37%, mean 27.9%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0.0–26%, mean 13.7%) at 0.01–2 m tall. Trees are occasionally emergent (0.0–21% cover, mean 12.1%) usually with hardwoods at 0–10 m tall. Total vegetation cover is 45.0–60%, mean cover is 53.3%.

In this association, the shrub layer is dominated primarily by *Sambucus mexicana* and secondarily by *Heteromeles arbutifolia.* A variety of other shrubs is often present at low cover including *Toxicodendron diversilobum, Malosma laurina, Mimulus aurantiacus,* and *Ceanothus megacarpus.* Other coastal sage and chaparral species are occasionally included in this layer. The herbaceous layer is variable and includes a variety of grasses and forbs. Often occurring is *Leymus condensatus* at low to moderate cover, while *Bromus, Marah macrocarpus, Cortaderia,* and *Cuscuta californica* are occasionally present. The tree layer sometimes includes *Quercus agrifolia* and/or *Juglans californica.*

Spartium junceum Shrubland Alliance

Spanish Broom Shrubland Alliance

Mapping Code: 9542

Local Description

Summary:
This shrubland alliance occurs on gentle to steep northeast-facing slopes at low to mid elevations between 226–820 m. It is dominated by *Spartium junceum* in the shrub layer and several nonnative grasses and forbs in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia* and nonnative *Pinus* sp.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 226–820 m, mean 478 m
Aspect: northeast
Slope: range 2–38 degrees, mean 25.8 degrees
Topography (micro; macro): flat or undulating; mid to upper slope
Litter Cover: no data
Small Rock Cover: range 5–25%, mean 16.2%
Large Rock Cover: range 0–20%, mean 5.5%
Bare Ground: range 5–40%, mean 19.2%
Parent Material: igneous, quaternary, or sedimentary
Soil Texture: coarse loamy sand

Vegetation Description:
Stands of this shrubland alliance form an open to intermittent shrub layer (21–53%, mean 33.6%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–6%, mean 2.6%) at 0–1 m tall. Trees are occasionally emergent (0–8% cover, mean 1.4%) with conifers at 0–10 m tall and hardwoods at 0–10 m tall. Total vegetation cover is 25–55%, mean cover is 36%.

In this association, the shrub layer is characterized by *Spartium junceum. Malosma laurina* and *Salvia mellifera* are occasionally included in this layer. The tree layer is emergent and open and may include *Quercus agrifolia and Pinus* sp. at low cover. The herbaceous layer is diverse and sometimes includes *Bromus madritensis* and *Foeniculum vulgare.* Other herbs may include *Centaurea melitensis, Malacothrix saxatilis,* and *Bromus diandrus.*

Samples Used in Description: (n = 7)
AA0641, rap0010, rap0011m, rap0015, rap0242m, rap0276, rap0278

Comments:
This alliance apparently began as plantations or seedings along road cuts on several major roads crossing the Santa Monica Mountains. These stands have persisted but so far have not proliferated much beyond their originally established locations.

Phases:
None

COMMON NAME	Spanish Broom Shrubland Alliance
SYNONYM	Broom Stands (Sawyer and Keeler-Wolf 1995)
PHYSIOGNOMIC CLASS	Shrubland

PHYSIOGNOMIC SUBCLASS	Evergreen shrubland
PHYSIOGNOMIC GROUP	Microphyllous evergreen shrubland
PHYSIOGNOMIC SUBGROUP	Natural/Seminatural
FORMATION	Microphyllous evergreen shrubland
ALLIANCE	*Spartium junceum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	Exotic

Global Description

Distribution:
In California broom stands occur throughout the southern, central, and northern California coast ranges; the Klamath Mountains and southern Cascades; the southern California mountains and valleys; and the Sierra Nevada Mountains and its foothills. This Spanish broom alliance, recently segregated from the generic broom alliance of Sawyer and Keeler-Wolf 1995, is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
All upland slopes; elevation sea level–1,000 m

Vegetation Description:
Cytisus scoparius, Genista monspessulana, Spartium junceum, or *Ulex europaea* is the sole dominant shrub in the canopy; other species of *Cytisus* or *Genista* may be present. Emergent trees may be present. Shrubs are less than 6 m; canopy is continuous. Ground layer is sparse.

Comments:
The following statement is taken from Sawyer et al. 2006 MS: Invasiveness of broom species is well appreciated. Ten species of broom or gorse from four legume genera are included in this type. Hickman 1993 recognizes three *Cytisus*, five *Genista*, one *Spartium*, and one *Ulex* in California. French broom, Spanish broom, and Scotch broom are the major invading brooms of disturbed areas in the state. The following are uncommon or locally common: *Cytisus multiflorus*, *Cytisus striatus*, *Genista canariensis*, *Genista linifolia*, *Genista maderensis*, *Genista stenopetala*, and *Ulex europaea*. In areas where trees form dense canopies with age, broom is killed; however, a persistent seed bank remains. The treatment here is broad, recognizing the importance of these introduced species in the vegetation of California. The most invasive species in central California appears to be *Genista monspessulana.* It is likely that with further sampling, individual broom alliances and associations will be defined. These may include Spanish broom (*Spartium juncea*) from southern coastal California, French broom (*Genista monspessulana*) from central California, and Scotch broom (*Cytisus multiflorus*) from northern California.

Hickman 1993, Sawyer and Keeler-Wolf 1995, Sawyer et al. 2006 MS

Toxicodendron diversilobum-Artemisia californica/Leymus condensatus Shrubland Association

Poison Oak-California Sagebrush/Giant Wild Rye Shrubland Association
***Toxicodendron diversilobum* Shrubland Alliance**
Poison Oak Shrubland Alliance

Mapping Code: 3331

Local Description

Summary:
This shrubland association occurs on somewhat steep to steep northwest- and northeast-facing slopes at low elevations between 0-719 m. It is characterized by a strong dominance of *Toxicodendron diversilobum* and a presence of *Artemisia californica* in the shrub layer. The herbaceous layer is characterized by relatively high cover of *Leymus condensatus.* The emergent tree layer may include *Juglans californica* and *Quercus agrifolia*.

Distribution:
This association is sampled in the Immediate Coast, Simi Hills Inland, Western Fog Zone, Upper Elevation Santa Monica Mountains, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 0–719 m, mean 297.6 m
Aspect: northwest and northeast
Slope: range 15–36 degrees, mean 31.1 degrees
Topography (micro; macro): variable (all); lower to upper slope
Litter Cover: range 55–55%, mean 55%
Small Rock Cover: range 3–5%, mean 4.3%
Large Rock Cover: range 0–8%, mean 2.7%
Bare Ground: range 11–35%, mean 22%
Parent Material: sedimentary
Soil Texture: moderately fine silty clay loam

Vegetation Description:
Stands of *Toxicodendron diversilobum-Artemisia californica/Leymus condensatus* Shrubland form an open to continuous shrub layer (28–75%, mean 49.6%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 0–5 m tall. The herbaceous layer is open (0–20%, mean 5%) at 0–1 m tall. Trees are occasionally emergent (0–3% cover, mean 0.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 36–75%, mean cover is 55.1%.

In this association, the shrub layer is dominated by *Toxicodendron diversilobum. Artemisia californica* is also characteristically present. *Sambucus mexicana* and *Malosma laurina* are frequently included in this layer. The tree layer is emergent and open and may infrequently include *Juglans californica* and *Quercus agrifolia* at low cover. The herbaceous layer is simple and is characterized by *Leymus condensatus.* Other herbs sometimes include *Melica imperfecta* and *Hirschfeldia incana*.

Comments:
This is a broadly defined association that occurs from the immediate coast in mesic hollows receiving salt-laden fog to interior sheltered mesic slopes above 700 m elevation. Most of the stands are found coastally and have *Artemisia californica* and *Leymus condensatus.* Stands are usually small and associated with mesic coastal scrub stands or *Quercus agrifolia* stands. Seasonality of sampling may have resulted in lower covers for *Toxicodendron diversilobum* as it looses all leaves in the winter.

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This association is likely to be found in other areas along the central and southern coast of California. The mixed evergreen and winter deciduous classification at the formation group level of the hierarchy is debatable, as many stands of this and other associations in this alliance are strongly dominated by the winter deciduous *Toxicodendron diversilobum*.

References:
None

Toxicodendron diversilobum-Mimulus aurantiacus Shrubland Association

Poison Oak-Bush Monkey Flower Shrubland Association
***Toxicodendron diversilobum* Shrubland Alliance**
Poison Oak Shrubland Alliance

Mapping Code: 3332

Local Description

Summary:
This shrubland association occurs on steep to very steep northeast- and northwest-facing slopes at low elevations between 125–591 m. It is characterized by a codominance of *Toxicodendron diversilobum* and *Mimulus aurantiacus* in the shrub layer. There are no characteristic species in the herbaceous layer. The emergent tree layer includes *Quercus agrifolia* in about half the stands.

Distribution:
This association is sampled in the Dry Inland, Eastern Urban, Immediate Coast Upper Elevation Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 125–591 m, mean 282.7 m
Aspect: northeast and northwest
Slope: range 32–55 degrees, mean 39.6 degrees
Topography (micro; macro): variable (all); lower to upper slope
Litter Cover: no data
Small Rock Cover: range 20–20%, mean 20%
Large Rock Cover: range 6–6%, mean 6%
Bare Ground: range 30–30%, mean 30%
Parent Material: igneous
Soil Texture: moderately fine sandy clay loam

Vegetation Description:
Stands of *Toxicodendron diversilobum-Mimulus aurantiacus* Shrubland form an open to intermittent shrub layer (33–58%, mean 40.1%). Shrubs occur in two different strata with low shrubs at 0–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (0–7%, mean 2.1%) at 0–1 m tall. Trees are occasionally emergent (0–4% cover, mean 2.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 36–60%, mean cover is 44.1%.

In this association, the shrub layer is characterized by *Toxicodendron diversilobum* and *Mimulus aurantiacus. Artemisia californica, Malosma laurina,* and *Salvia leucophylla* are usually included in this layer. The tree layer is emergent and open and may occasionally include *Quercus agrifolia* and *Quercus lobata* at low cover. The herbaceous layer is simple and sometimes includes *Leymus condensatus, Melica imperfecta,* and *Bromus diandrus.*

	BRDI3	*Bromus diandrus*	29	0.3	0.2	2.0			X

Other Noteworthy Species:
None

Nonnative Species:
Bromus diandrus, Stellaria media, Ageratina adenophora, Avena, Carduus pycnocephalus, Centaurea melitensis, Foeniculum vulgare, Hirschfeldia incana

Samples Used in Description: (n = 7)
AA0575, AA0577, rap0836m, rap1671, rap1838, rap1904, rap2390m

Comments:
This association appears to be rare in the study area. It bears ecological relationships with *Quercus agrifolia* stands (often occurs on steep concave slopes adjacent to them) and also occurs adjacent to *Artemisia californica* Alliance stands in the coastal scrub. The presence of *Mimulus aurantiacus* in the study area often indicates steep but relatively mesic unstable slopes.

Phases:
None

COMMON NAME	Poison Oak-Bush Monkey Flower Shrubland Association
SYNONYM	None
FORMATION CLASS	III. Shrubland
FORMATION SUBCLASS	III.C. Mixed evergreen deciduous shrubland
FORMATION GROUP	III.C.2. Mixed evergreen cold-deciduous shrubland
FORMATION SUBGROUP	III.C.2.N. Natural/Seminatural mixed evergreen cold-deciduous shrubland

FORMATION NAME	III.C.2.N.a. Mixed evergreen cold-deciduous shrubland
ALLIANCE	*Toxicodendron diversilobum* Shrubland Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3?

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Both *Toxicodendron diversilobum* and *Mimulus aurantiacus* are widespread shrubs in coastal California ranging well north and south of the study area. It is likely that this association occurs farther north into the outer central coast ranges (e.g., Big Sur, Monterey County).

Venegasia carpesioides Shrubland Alliance

Canyon Sunflower Shrubland Alliance

Mapping Code: 4750

Local Description

Summary:
This shrubland alliance occurs on steep northwest- and northeast-facing slopes at low elevations between 25–534 m. It is dominated by the leafy shrub *Venegasia carpesioides* in the shrub layer. There is a diverse herbaceous layer characterized by *Leymus condensatus.* The emergent tree layer includes *Quercus agrifolia*.

Distribution:
This alliance is sampled in the Upper Elevation Santa Monica Mountains and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 25–534 m, mean 211.4 m
Aspect: northwest and northeast
Slope: range 28–38 degrees, mean 33 degrees
Topography (micro; macro): undulating, concave, or convex; middle slope to ridge
Litter Cover: no data
Small Rock Cover: range 5–25%, mean 12.7%
Large Rock Cover: range 0–2%, mean 0.7%
Bare Ground: range 10–30%, mean 23.3%
Parent Material: igneous or sedimentary
Soil Texture: medium loam to moderately fine clay loam

Vegetation Description:
Stands of this shrubland alliance form an open to intermittent shrub layer (28–50%, mean 40.4%). Shrubs occur in two different strata with low shrubs at 0.5–2 m tall and tall shrubs at 1–5 m tall. The herbaceous layer is open (2–15%, mean 9%) at 0–1 m tall. Trees are occasionally emergent (0–8% cover, mean 1.6%) with hardwoods at 0–10 m tall. Total vegetation cover is 40–65%, mean cover is 50.2%.

In this association, the shrub layer is characterized by *Venegasia carpesioides, Malosma laurina,* and *Heteromeles arbutifolia*. *Mimulus aurantiacus, Artemisia californica, Salvia mellifera,* and *Toxicodendron diversilobum* are occasionally included in this layer. The tree layer is emergent and open and occasionally includes *Quercus agrifolia* at low cover. The herbaceous layer is diverse and is characterized by *Leymus condensatus* with *Bromus* sp. also occasionally present. Other herbs occasionally present may include *Hirschfeldia incana, Nassella pulchra, Brassica nigra,* and *Lathyrus laetiflorus.*

Other Noteworthy Species:
Baccharis plummerae was found in 1 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-1-3. Global rank is G3T3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Juglans californica was found in 1 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2 (CNPS 2005). Federal listing is none, and state listing is none (SAMO 2004).

Nonnative Species:
Hirschfeldia incana, Brassica nigra, Bromus diandrus, Nicotiana glauca, Cortaderia, Medicago polymorpha, Nerium oleander

Samples Used in Description: (n = 5)
AA0325cc, rap0464, rap0927, rap1122, rap2656

Comments:
Stands dominated by canyon sunflower dominate on typically sheltered, northerly facing or concave slopes. They typically occur following burns in *Quercus agrifolia* woodlands or mesic chaparral such as the *Ceanothus spinosus* or *Quercus berberidifolia* alliances. Fire in mesic coastal scrub formerly dominated by *Artemisia californica*, *Mimulus aurantiacus*, and *Leymus condensatus* may also be dominated by *V. carpesioides*. Typically, canyon sunflower dominates for several years before shifting toward more long-persisting shrub dominance. Canyon sunflower occurs commonly in such situations along the coast of southern California but has only been sampled extensively in the Santa Monica Mountains in this study so far. Little detail is currently known about the duration of stands following fire. It appears to resprout and perhaps proliferate following fire and returns to relatively low cover and density in the understory of other shrubs and trees following intervals of more than 10 years without fire.

Phases:
None

HERBACEOUS VEGETATION DESCRIPTIONS

Arundo donax Herbaceous Alliance

Giant Reed Herbaceous Alliance

Mapping Code: 4310

Local Description

Summary:
Two stands of this herbaceous alliance occur on flat to steep, northeast-facing slopes at low elevations between 2 and 153 m. It is dominated by *Arundo donax* in the herbaceous layer. *Artemisia douglasiana*, *Foeniculum vulgare,* and *Malacothrix saxatilis* may also be included in this layer at low cover. *Baccharis pilularis* is found in the shrub layer at low cover, and *Platanus racemosa* is in the tree layer at low cover.

Distribution:
This association is sampled in the Immediate Coast region of the study area. It has also been seen in the Simi Valley, though not sampled there.

Environmental Description:
Elevation: range 2–153 m, mean 78 m
Aspect: flat to northeast
Slope: 0 to 34 degrees
Topography (micro; macro): flat to convex; bottom to mid
Litter Cover: 90% (in one sample)
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: depositional
Soil Texture: sand (class unknown)

Vegetation Description:
Stands of this herbaceous alliance form an open to intermittent herbaceous layer (16–50%, mean 33%) at 2–5 m tall. The shrub layer is sparse to open (0–25%, mean 12.5%) at 0–5 m tall. Trees are emergent (1–4% cover, mean 2.5%) with hardwoods at 2–10 m tall. Total vegetation cover is 45–51%, mean cover is 48%.

In this alliance, the herbaceous layer is open to intermittent and is dominated by *Arundo donax*. This layer may also include *Artemisia douglasiana*, *Foeniculum vulgare,* and *Malacothrix saxatilis* at low cover. The shrub layer is low in cover and may include *Baccharis pilularis, Myoporum laetum, Heteromeles arbutifolia, Artemisia californica,* and *Malacothamnus fasciculatus*, and the tree layer may include *Platanus racemosa* as a sparse emergent.

None

Nonnative Species:
Arundo donax, Myoporum laetum, Foeniculum vulgare, Nicotiana glauca

Samples Used in Description: (n = 2)
rap1361, rap2207m

Comments:
This is a dangerously invasive nonnative alliance that, once established, is very difficult to remove. It is easily spread along active stream channels during flooding events when the underground stolon and rootstalks are damaged, uprooted, and transported by water to new locations. This species is sometimes used as an ornamental locally.

Phases:
None

COMMON NAME	Giant Reed Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.A. Perennial graminoid vegetation
PHYSIOGNOMIC GROUP	V.A.5. Temperate or subpolar grassland
PHYSIOGNOMIC SUBGROUP	V.A.5.N. Natural/Seminatural temperate or subpolar grassland
FORMATION	V.A.5.N.i. Intermittently flooded temperate or subpolar grassland

ALLIANCE	*Arundo donax* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	None, invasive exotic

Global Description

Distribution:
This alliance is known from the Santa Monica Mountains region and also from elsewhere in California from Shasta County south to San Diego County. The species is introduced from Eurasia.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This alliance occurs on banks of streams, rivers, sloughs, and other water bodies in lower elevations of California.

Vegetation Description:
Dense monospecific clumps tend to form interspersed with native woody species such as *Salix lasiolepis, S. exigua, S. gooddingii, Baccharis salicifolia*, and so forth, along gravelly stream channels.

Comments:
This alliance is spreading throughout lower elevation riparian settings in California from the northern Central Valley to San Diego County along coastal streams and estuaries.

Bossard et al. 2000

Avena fatua Herbaceous Association

Wild Oat Herbaceous Association
***Avena* spp. Herbaceous Alliance**
Wild Oat Herbaceous Alliance

Mapping Code: 4220

Local Description

Summary:
This herbaceous association occurs on gentle to steep often northwest- or southwest-facing slopes at low elevations between 165 and 268 m. *Avena fatua* is characteristically abundant in the herbaceous layer, and *Bromus diandrus* and *Brassica nigra* are often present. *Lotus scoparius, Baccharis pilularis*, and *Artemisia californica* are sometimes found in the shrub layer at low cover, and *Quercus agrifolia* is infrequently in the tree layer at low cover.

Distribution:
This association is sampled in the Upper Elevation Santa Monica Mountains, Western Fog Zone, Dry Inland, and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 165–268 m, mean 214.6 m
Aspect: variable, but often northwest and southwest
Slope: range 2–35 degrees, mean 9.25 degrees
Topography (micro; macro): flat to undulating; most often bottom to mid
Litter Cover: range 35–60%, mean 51.7%
Small Rock Cover: range 0–8%, mean 2.3%
Large Rock Cover: range 0–2%, mean 0.3%
Bare Ground: range 0–35%, mean 10.3%
Parent Material: most often depositional or sedimentary, occasionally igneous
Soil Texture: fine or moderately fine clay

Vegetation Description:
Stands of the *Avena fatua* Herbaceous Association form an intermittent to continuous herbaceous layer (40–90%, mean 58.3%) at 0.01–1 m tall. The shrub layer is sparse to open (0–10%, mean 2.8%) at 0–2 m tall. Trees are infrequently emergent (0–0% cover, mean 0%) with hardwoods at 0–10 m tall. Total vegetation cover is 40–90%, mean cover is 61.1%.

In this association, the herbaceous layer is intermittent to continuous, and *Avena fatua* is characteristic. *Bromus diandrus* and *Brassica nigra* are often included in this layer. The shrub layer occasionally includes *Lotus scoparius, Baccharis pilularis*, and *Artemisia californica*. The tree layer infrequently includes *Quercus agrifolia* as an emergent.

AA0947, rap0944, rap0946, rap1000, rap1262, rap1841, rap2527rlv, rap2528rlv

Comments:
This is the first report that has specifically defined an *Avena* sp. Alliance. Typically, these stands have been placed into the California annual grassland alliance (Sawyer and Keeler-Wolf 1995). All of these annual alliances vary greatly depending on annual climatic conditions.

Phases:
None

COMMON NAME	Wild Oat Herbaceous Association
SYNONYM	California Annual Grassland (Sawyer and Keeler-Wolf 1995), Nonnative Grassland (Holland 1986), *Bromus* (*diandrus, hordeaceus, madritensis*) Herbaceous Alliance (Reid et al. 1999)
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.D. Annual graminoid or forb vegetation

PHYSIOGNOMIC GROUP	V.D.2. Temperate or subpolar annual grasslands or forb vegetation
PHYSIOGNOMIC SUBGROUP	V.D.2.N. Natural/Seminatural
FORMATION	Medium-Tall temperate annual grassland (This is debatable.)
ALLIANCE	California Annual Grassland/Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5 Note: Although *Avena fatua* and *A. barbata* were both introduced from Eurasia, the *Avena* stands may house a number of significant native annuals and perennial herbs. Thus, this is considered an association that has some conservation value.

Global Description

Distribution:
This association is defined from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. It is likely to be extremely widespread throughout cismontane California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
A similar association has been identified in the central coast ranges: *Avena barbata-Avena fatua* Association.

California Annual Grassland/Herbaceous Alliance

Annual Grassland/Herbaceous Herbaceous Alliance

Mapping Code: 4340/5000

The California annual grassland alliance is represented by four associations locally. In addition to these, there is additional variation expressed in the herbaceous layer within six samples, which will be briefly described here. These samples occur on flat to steep slopes and from low to moderate elevations. Most of them had low cover of all species, but they were dominated by a high-diversity herb layer, thus making them hard to classify further than the alliance level. *Bromus diandrus, Brassica nigra,* and *Hirschfeldia incana* are the three species with the highest constancy in these six plots, and none had constancy greater than 67%. In addition, a variety of forbs also occurred across the stands and usually dominated the stands including *Camissonia bistorta, Lasthenia californica, Lotus* sp*., Lupinus succulentus, Hemizonia fasciculata,* and *Vicia villosa*. Further, *Calochortus catalinae* was found in 1 of 6 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Samples classified to the alliance level only:
AA1064, rap1326, rap1712, rap2519rlv, rap2520rlv, rap2640rlv

Brassica nigra Herbaceous Association

Black Mustard Herbaceous Association
California Annual Grassland/Herbaceous Herbaceous Alliance

Mapping Code: 50006

Local Description

Summary:
This herbaceous association occurs on flat to steep, often northwest-facing slopes at low elevations between 7 and 436 m. *Brassica nigra* is characteristically abundant in the herbaceous layer, and *Leymus condensatus* is usually present. *Encelia californica* and *Artemisia californica* are occasionally found in the shrub layer at low cover, and *Juglans californica* is occasionally in the tree layer at low cover.

Distribution:
This association is sampled in the Dry Inland, Immediate Coast, Eastern Urban, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 7–436 m, mean 270 m
Aspect: variable, but most often northwest
Slope: range 0–45 degrees, mean 22.8 degrees
Topography (micro; macro): no data
Litter Cover: range 20–80%, mean 43.3%
Small Rock Cover: range 2–30%, mean 13.4%
Large Rock Cover: no data
Bare Ground: range 10–78%, mean 38.6%
Parent Material: most often sedimentary, sometimes depositional
Soil Texture: fine to moderately fine clay or silty clay loam

Vegetation Description:
Stands of the *Brassica nigra* Herbaceous Association form an open to continuous herbaceous layer (18–70%, mean 37.5%) at 0.01–2 m tall. The shrub layer is sparse to open (0–12%, mean 4.4%) at 0–5 m tall. Trees are sometimes emergent (0–7% cover, mean 1.5%) with hardwoods at 0–10 m tall. Total vegetation cover is 23–70%, mean cover is 42.7%.

In this association, the herbaceous layer is open to continuous, and *Brassica nigra* is characteristically abundant. *Bromus diandrus* and *Leymus condensatus* are usually included in this layer at low cover. The shrub layer occasionally includes *Encelia californica* and *Artemisia californica* at sparse cover. The tree layer occasionally includes *Juglans californica* as an emergent, while *Quercus agrifolia* and *Sambucus mexicana* occur infrequently at low cover.

***Brassica nigra* Association**

Other Noteworthy Species:
Juglans californica was found in 4 of 11 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Brassica nigra, Bromus diandrus, Nicotiana glauca, Marrubium vulgare, Centaurea melitensis, Silybum marianum, Melilotus indicus, Conium maculatum, Lactuca serriola, Erodium moschatum, Erodium cicutarium, Ricinus communis, Bromus madritensis, Pennisetum setaceum, Sisymbrium

Samples Used in Description: (n = 11)
AA0931, rap1062, rap1065, rap1101, rap1329, rap1422, rap1442, rap1873m, rap1888, rap2059, rap2916rlv

Comments:
Although *Brassica nigra* forms weedy stands throughout much of cismontane California, this is the first time this association has been formally defined. In this report, we are considering it an expansion of the widely known California annual grassland alliance, now modified as the California annual grassland/herbaceous alliance to account for some associations being dominated by annual herbs instead of grasses. Some of the stands surveyed here seemed to be associated with a recent prescribed burn.

Phases:
None

COMMON NAME Black Mustard Herbaceous Association
SYNONYM California Annual Grassland (Sawyer and Keeler-Wolf 1995), Nonnative Grassland (Holland 1986),

	Bromus (*diandrus, hordeaceus, madritensis*) Herbaceous Alliance (Reid et al. 1999)
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.D. Annual graminoid or forb vegetation
PHYSIOGNOMIC GROUP	V.D.2. Temperate or subpolar annual grasslands or forb vegetation
PHYSIOGNOMIC SUBGROUP	V.D.2.N. Natural/Seminatural
FORMATION	Medium-Tall temperate annual grassland (This is debatable.)
ALLIANCE	California Annual Grassland/Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5—Note: *Brassica nigra* stands are generally strongly dominated by *B. nigra*, an invasive weed with low conservation value; however, some stands may have conservation value due to the seasonal nature of the vegetation and the possibility of native species of limited range inhabiting these stands.

Global Description

Distribution:
This association is only sampled from the Santa Monica Mountains region. However, it is anecdotally known from much of cismontane California in disturbed pastures and grasslands.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Brassica nigra-Bromus diandrus Herbaceous Association

Black Mustard-Ripgut Brome Herbaceous Association
California Annual Grassland/Herbaceous Alliance

Mapping Code: 50009

Local Description

Summary:
This herbaceous association occurs on gentle to very steep slopes of variable aspect at low elevations between 37 and 495 m. It is codominated by *Bromus diandrus* and *Brassica nigra* in the herbaceous layer. *Malosma laurina, Hazardia squarrosa, Artemisia californica*, and *Salvia leucophylla* are sometimes found in the shrub layer at low cover, and *Quercus lobata, Q. agrifolia, Juglans californica*, and *Pinus* spp. are infrequently found in the tree layer at low cover.

Distribution:
This association is sampled in the Dry Inland, Eastern Urban, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, Simi Hills Inland, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 37–495 m, mean 321.4 m
Aspect: variable
Slope: range 2–48 degrees, mean 19.0 degrees
Topography (micro; macro): most often undulating or flat; variable
Litter Cover: range 25–85%, mean 60.3%
Small Rock Cover: range 0–70%, mean 11%
Large Rock Cover: range 0–2%, mean 0.7%
Bare Ground: range 0–64%, mean 23.3%
Parent Material: usually sedimentary, sometimes igneous, depositional, or metamorphic
Soil Texture: fine clay or moderately fine sandy or silty clay loam

Vegetation Description:
Stands of the *Brassica nigra-Bromus diandrus* Herbaceous Association form an open to intermittent herbaceous layer (16–65%, mean 42.3%) at 0.01–1 m tall. The shrub layer is sparse to open (0–12%, mean 3%) at 0–5 m tall. Trees are infrequently emergent (0–8% cover, mean 0.5%) with hardwoods at 0–15 m tall. Total vegetation cover is 20–65%, mean cover is 45.7%.

In this association, the herbaceous layer is open to intermittent and is codominated by *Bromus diandrus* and *Brassica nigra*. Other nonnative species such as *Centaurea melitensis*, *Hirschfeldia incana*, and *Avena fatua* are also occasionally included in this layer at relatively low cover. The shrub layer sometimes includes *Malosma laurina, Hazardia squarrosa, Artemisia californica*, and *Salvia leucophylla*. The tree layer infrequently includes *Quercus lobata, Q. agrifolia, Juglans californica*, and *Pinus* spp. as emergent trees.

Other Noteworthy Species:
Ericameria palmeri was found in 1 of 24 surveys of this plant community, which could be the rare variety *E. p.* var. *pachylepis.* Regionally, the park considers this species as Rare. CNPS ranks this species as List 0, and CNPS R-E-D Code is 0-0-0. Global rank is none, and state rank is none. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Juglans californica was found in 2 of 24 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Brassica nigra, Bromus diandrus, Centaurea melitensis, Hirschfeldia incana, Avena fatua, Lactuca serriola, Nicotiana glauca, Bromus madritensis, Erodium, Erodium cicutarium, Melilotus indicus, Medicago polymorpha, Carduus pycnocephalus, Marrubium vulgare, Vicia villosa, Sonchus oleraceus, Avena, Silybum marianum, Foeniculum vulgare, Raphanus sativus, Ricinus communis, Malva parviflora, Rumex crispus, Euphorbia terracina, Galium aparine, Anagallis arvensis, Bromus hordeaceus, Cirsium vulgare, Melilotus albus, Melilotus officinalis, Pennisetum setaceum, Salsola tragus, Stellaria media

Samples Used in Description: (n = 24)
AA0044cc, AA0101cc, AA0111cc, AA0145cc, AA0168cc, AA0310cc, AA0324cc, AA0731, rap0733, rap0764, rap0820, rap1041, rap1094m, rap1246, rap1317, rap1502, rap1554, rap1571, rap2521rlv, rap2522rlv, rap2771, rap2891rlv, rap2892rlv, rap2917rlv

Comments:
Stands of this association are typically the result of high disturbance through grazing, fire, clearing, mechanical treatments, or a combination of the above. All three of the associations with mixtures of *Brassica nigra* and annual herbs and grasses may be considered closely related. They may ultimately be lumped into a single black mustard-weedy herbaceous association of the California annual grassland alliance. However, since analysis suggests these types do separate

out at least floristically, we are maintaining their distinction here until further detailed releve-based sampling is done to determine their relationships.

Phases:
None

Brassica nigra-Centaurea melitensis Herbaceous Association

Black Mustard-Maltese Star Thistle Herbaceous Association
California Annual Grassland/Herbaceous Herbaceous Alliance

Mapping Code: 50008

Local Description

Summary:
This herbaceous association occurs on gentle to steep slopes of variable aspect at low elevations between 41 and 483 m. It is codominated by *Centaurea melitensis* and *Brassica nigra* in the herbaceous layer. *Hazardia squarrosa, Salvia leucophylla,* and *Artemisia californica* are often found in the shrub layer at low cover, and *Juglans californica* and *Quercus agrifolia* are infrequently in the tree layer at low cover.

Distribution:
This association is sampled in the Dry Inland, Upper Elevation Santa Monica Mountains, Eastern Urban, Immediate Coast, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 41–483 m, mean 319.9 m
Aspect: variable
Slope: range 2–35 degrees, mean 16 degrees
Topography (micro; macro): usually flat or undulating; variable, but often mid to top
Litter Cover: range 10–60%, mean 35.3%
Small Rock Cover: range 0–60%, mean 12.3%
Large Rock Cover: range 0–2%, mean 0.9%
Bare Ground: range 4–75%, mean 35.8%
Parent Material: sedimentary
Soil Texture: fine to moderately fine clay or clay loam

Vegetation Description:
Stands of the *Brassica nigra-Centaurea melitensis* Herbaceous Association form an open to intermittent herbaceous layer (10–65%, mean 28.9%) at 0.01–1 m tall. The shrub layer is sparse to open (0–18%, mean 6.2%) at 0–5 m tall. Trees are infrequently emergent (0–1% cover, mean 0.1%) with hardwoods at 0–5 m tall. Total vegetation cover is 15–65%, mean cover is 35%.

In this association, the herbaceous layer is open to intermittent and is codominated by *Centaurea melitensis* and *Brassica nigra*. *Bromus madritensis* usually occurs in this layer and *Avena fatua*, *Hirschfeldia incana*, and *Bromus diandrus* may also occasionally be found at relatively low cover. The shrub layer is open and often includes *Hazardia squarrosa, Salvia leucophylla,* and *Artemisia californica,* while *Malacothamnus fasciculatus, Encelia californica*, and *Eriogonum cinereum* are also sometimes present. The tree layer infrequently includes *Juglans californica* and *Quercus agrifolia* as sparse emergent trees.

Bromus diandrus Herbaceous Association

Ripgut Brome Herbaceous Association
California Annual Grassland/Herbaceous Herbaceous Alliance

Mapping Code: 50005

Local Description

Summary:
This herbaceous association occurs on flat to steep often northwest- or southwest-facing slopes at elevations between 31 and 613 m. *Bromus diandrus* is abundant in the herbaceous layer and *Brassica nigra* is often present at low cover. *Malosma laurina, Baccharis pilularis, Sambucus mexicana, Ceanothus megacarpus, Salvia mellifera,* and *Heteromeles arbutifolia* are occasionally found in the shrub layer at low cover, and *Quercus agrifolia* is infrequently found in the tree layer at low cover.

Distribution:
This association is sampled in the Eastern Urban, Western Fog Zone, Upper Elevation Santa Monica Mountains, Immediate Coast, Dry Inland, and Simi Hills Inland regions of the study area.

Environmental Description:
Elevation: range 31–613 m, mean 260.9 m
Aspect: variable, but most often southwest or northwest
Slope: range 0–40 degrees, mean 19.4 degrees
Topography (micro; macro): usually flat or undulating; variable
Litter Cover: range 35–60%, mean 47.5%
Small Rock Cover: range 0–30%, mean 9.4%
Large Rock Cover: range 0–45%, mean 5.6%
Bare Ground: range 1–62%, mean 21.6%
Parent Material: usually igneous or sedimentary, sometimes depositional
Soil Texture: moderately fine sandy or silty clay loam

Vegetation Description:
Stands of the *Bromus diandrus* Herbaceous Association form an open to continuous herbaceous layer (10–90%, mean 38.9%) at 0.01–1 m tall. The shrub layer is sparse to open (0–22%, mean 8.4%) at 0–5 m tall. Trees are infrequently emergent (0–10% cover, mean 1.3%) with hardwoods at 0–15 m tall and conifers at 0–10 m tall. Total vegetation cover is 15–90%, mean cover is 47.9%.

In this association, the herbaceous layer is open to continuous and *Bromus diandrus* is abundant. Other herbs occur at relatively low cover; for example, *Brassica nigra* is often included, and *Hirschfeldia incana* and *Centaurea melitensis* sometimes occur in this layer. The shrub layer occasionally includes *Malosma laurina, Baccharis pilularis, Sambucus mexicana, Ceanothus megacarpus, Salvia mellifera,* and *Heteromeles arbutifolia*. The tree layer infrequently includes *Quercus agrifolia* as an emergent.

Other Noteworthy Species:
Juglans californica was found in 3 of 22 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Bromus diandrus, Brassica nigra, Centaurea melitensis, Hirschfeldia incana, Avena fatua, Bromus hordeaceus, Carduus pycnocephalus, Melilotus indicus, Erodium cicutarium, Marrubium vulgare, Erodium, Bromus madritensis, Piptatherum miliaceum, Malva parviflora, Nicotiana glauca, Silybum marianum, Vicia sativa, Acacia redolens, Avena barbata, Conium maculatum, Erodium botrys, Eucalyptus, Phalaris aquatica, Anagallis arvensis, Avena, Cirsium vulgare, Cistus, Lactuca serriola, Raphanus sativus, Rosmarinus officinalis, Sonchus oleraceus

Samples Used in Description: (n = 22)
AA0302cc, AA0409, AA0410, AA0810, AA0913, AA0968, rap0038, rap0203, rap0243, rap0371, rap0448, rap0634, rap0759, rap0842, rap1235, rap1319, rap1689, rap2337, rap2523rlv, rap2524rlv, rap2525rlv, rap2893rlv

Comments:
Although this common association of the California annual grassland/herbaceous alliance shares species with the *Brassica nigra* associations of the same alliance, it is overwhelmingly dominated by *Bromus diandrus.* The plots listed without *B. diandrus* in the summary table all have *Bromus* sp. listed (unidentified to species due to poor phenology) and are all likely to be *B. diandrus.* It remains to be seen how environmentally distinct this association is from the other weedy associations in the same alliance (e.g., those with *Brassica nigra*); however, it does seem to favor slightly wetter areas and slightly deeper soils than the *Brassica nigra* Alliance.

Phases:
None

COMMON NAME	Ripgut Brome Herbaceous Association
SYNONYM	California Annual Grassland (Sawyer and Keeler-Wolf 1995), Nonnative Grassland (Holland 1986), *Bromus* (*diandrus, hordeaceus, madritensis*) Herbaceous Alliance (Reid et al. 1999)
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.D. Annual graminoid or forb vegetation
PHYSIOGNOMIC GROUP	V.D.2. Temperate or subpolar annual grasslands or forb vegetation
PHYSIOGNOMIC SUBGROUP	V.D.2.N. Natural/Seminatural
FORMATION	Medium-Tall temperate annual grassland (This is debatable.)
ALLIANCE	California Annual Grassland/Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5—Note: These stands are generally strongly dominated by *Bromus diandrus*, an invasive weed with low conservation value; however, some stands may have conservation value due to the seasonal nature of the vegetation and the possibility of native species of limited range inhabiting these stands.

Global Description

Distribution:
This association is only sampled from the Santa Monica Mountains region. However, it has been widely observed (but not sampled) in other parts of cismontane California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Bromus diandrus-Avena spp. Herbaceous Association

Ripgut Brome-Wild Oat Herbaceous Association
California Annual Grassland/Herbaceous Herbaceous Alliance

Mapping Code: 50007

Local Description

Summary:
This herbaceous association occurs on gentle to somewhat steep slopes of variable aspect at elevations between 15 and 550 m. *Bromus diandrus* is characteristically present in the herbaceous layer and usually codominates with *Avena fatua* or *A. barbata. Brassica nigra* is also usually found in this layer at low cover. *Hazardia squarrosa, Artemisia californica,* and *Lotus scoparius* are occasionally found in the shrub layer at low cover, and *Quercus lobata* infrequently occurs in the tree layer at low cover.

Distribution:
This association is sampled in the Immediate Coast, Upper Elevation Santa Monica Mountains, and Dry Inland regions of the study area.

Environmental Description:
Elevation: range 15–550 m, mean 293 m
Aspect: variable
Slope: range 2–15 degrees, mean 6.1 degrees
Topography (micro; macro): usually flat or undulating; variable
Litter Cover: range 20–60%, mean 37.5%
Small Rock Cover: range 0–30%, mean 7.2%
Large Rock Cover: range 0–2%, mean 0.3%
Bare Ground: range 1–74%, mean 28.9%
Parent Material: variable but frequently depositional or sedimentary
Soil Texture: variable, but often fine clay

Vegetation Description:
Stands of the *Bromus diandrus-Avena* spp. Herbaceous Association form an open to intermittent herbaceous layer (10–65%, mean 43.9%) at 0.01–1 m tall. The shrub layer is sparse to open (0–9%, mean 2.4%) at 0–5 m tall. Trees are infrequently emergent (0–1% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 13–70%, mean cover is 46.3%.

In this association, the herbaceous layer is open to intermittent, and *Bromus diandrus* is characteristically present and codominant with either *Avena fatua* or *A. barbata. Brassica nigra* is usually included in this layer at low cover while *Bromus madritensis, Bromus hordeaceus*, and *Marrubium vulgare* are occasionally present. Other forbs are occasionally present and sometimes abundant such as *Erodium botrys* and *Centaurea melitensis.* The shrub layer sometimes includes *Hazardia squarrosa, Artemisia californica,* and *Lotus scoparius.* The tree layer infrequently includes *Quercus lobata* as an emergent.

Distichlis spicata-Ambrosia chamissonis Herbaceous Association

Salt Grass-Dune Burweed Herbaceous Association
***Distichlis spicata* Herbaceous Alliance**
Salt Grass Herbaceous Alliance

Mapping Code: 4511

Local Description

Summary:
This herbaceous association occurs on flat to somewhat steep, often northeast slopes at low elevations between 0 and 15 m. It is dominated by *Distichlis spicata* in the herbaceous layer, and *Ambrosia chamissonis* is characteristically present as a subdominant. *Atriplex lentiformis*, *Atriplex watsonii*, and *Suaeda taxifolia* are sometimes found in the shrub layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 0–15 m, mean 4 m
Aspect: variable, but often northeast
Slope: range 0–15 degrees, mean 3.7 degrees
Topography (micro; macro): frequently flat; lower to bottom
Litter Cover: no data
Small Rock Cover: range 0–25%, mean 11%
Large Rock Cover: range 0–1%, mean 0.2%
Bare Ground: range 10–70%, mean 52%
Parent Material: depositional
Soil Texture: sand

Vegetation Description:
Stands of the *Distichlis spicata-Ambrosia chamissonis* Herbaceous Association form a sparse to intermittent herbaceous layer (0–44%, mean 12.1%) at 0.01–1 m tall. The shrub layer is open to intermittent (1–49%, mean 11.7%) at 0.01–2 m tall. Total vegetation cover is 2–55%, mean cover is 23.4%.

In this association, the herbaceous layer is sparse to intermittent and is dominated by *Distichlis spicata*, and *Ambrosia chamissonis* is characteristically present usually as a subdominant. *Cakile maritima, Arundo donax*, and *Carpobrotus edulis* are often included in this layer at low cover. The shrub layer occasionally includes *Atriplex lentiformis*, *Atriplex watsonii*, *Suaeda taxifolia*, and *Coreopsis gigantea* at low cover.

***Distichlis spicata-Ambrosia chamissonis* Association**

Other Noteworthy Species:
Abronia maritima was found in 2 of 7 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and the CNPS R-E-D Code is 1-2-2. Global rank is G4?, and state rank is S3?. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Eriogonum crocatum was found in 1 of 7 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.1. Federal listing is Species of Concern, and state listing is Rare (CNPS 2005, SAMO 2004).

*Suaeda taxifolia (*synonym *S. californica* var. *taxifolia)* was found in 2 of 7 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G3?, and state rank is S2S3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Cakile maritima, Arundo donax, Carpobrotus edulis, Cynodon dactylon, Melilotus, Salsola tragus, Erodium, Foeniculum vulgare, Nicotiana glauca, Osteospermum, Pennisetum setaceum, Tetragonia tetragonioides

Samples Used in Description: (n = 7)
rap0869, rap0871, rap0970, rap0971, rap1199m, rap1271, rap2612

Comments:
Although not sampled anywhere outside of the study area, this association is likely to be relatively rare. However, it is not unusual for the two nominate species to co-occur in coastal settings throughout California where brackish to saline lagoons and other bodies of water exist adjacent to sand flats or dunes.

Phases:
None

COMMON NAME	Salt Grass-Dune Burweed Herbaceous Association
SYNONYM	None

Distichlis spicata-Salicornia virginica-Jaumea carnosa Herbaceous Association

Salt Grass-Pickleweed-Marsh Jaumea Herbaceous Association
***Distichlis spicata* Herbaceous Alliance**
Salt Grass Herbaceous Alliance

Mapping Code: 4527

Local Description

Summary:
This herbaceous association occurs on flat to gently sloped ground at low elevations between 0 and 6 m. *Distichlis spicata* and *Jaumea carnosa* are codominant and characteristically present in the herbaceous layer, and *Salicornia virginica* is usually present and subdominant to codominant. *Frankenia salina* is characteristically found in the shrub layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 0–6 m, mean 3 m
Aspect: flat
Slope: no data
Topography (micro; macro): flat; bottom
Litter Cover: 10% (one sample)
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 60–80%, mean 70%
Parent Material: depositional
Soil Texture: sand to clay

Vegetation Description:
Stands of the *Distichlis spicata-Salicornia virginica-Jaumea carnosa* Herbaceous Association form an open to intermittent herbaceous layer (24–58%, mean 44.6%) at 0.01–0.5 m tall. The shrub layer is sparse to open (0–27%, mean 12.3%) at 0–2 m tall. Total vegetation cover is 51–70%, mean cover is 58.4%.

In this association, the herbaceous layer is open to intermittent, and *Jaumea carnosa* is characteristically present. *Distichlis spicata* and *Salicornia virginica* are also usually present. *Jaumea* and *Distichlis* are codominant, while *Salicornia* is subdominant to codominant. *Cuscuta salina*, *Melilotus indicus*, *Monanthochloe littoralis*, *Rumex crispus*, *Scirpus californicus*, and *Typha* spp. are also occasionally found in this layer at low cover. The shrub layer characteristically includes *Frankenia salina* at low cover, while *Batis maritima, Suaeda taxifolia,* and *Atriplex lentiformis* are also sometimes present.

Other Noteworthy Species:
*Suaeda taxifolia (*synonym *S. californica* var. *taxifolia)* was found in 2 of 7 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G3?, and state rank is S2S3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Melilotus indicus, Rumex crispus, Carpobrotus edulis, Oxalis pes-caprae

Samples Used in Description: (n = 7)
rap0904m, rap1012, rap1023, rap2647, rap2707, rap2772, rap2773

Comments:
The variation in the cover of *Distichlis* and *Salicornia* suggests that this association is perhaps better considered a part of a mixed alliance of *S. virginica* and *D. spicata*. However, at this point we remain conservative and select the *Distichlis spicata* Alliance because of the continuously higher cover of *Distichlis* and other nonwoody herbs such as *Jaumea carnosa*. There are several other plant associations listed for California that contain *D. spicata, J. carnosa,* and *S. virginica*. All have been placed in the *D. spicata* Alliance (e.g., *Distichlis spicata-Frankenia salina-Jaumea carnosa* from Point Reyes and *Jaumea carnosa-Distichlis spicata* from southern California).

This association is the most typical of the "upper" salt marsh associations locally. Its ecological position is typically slightly more elevated and more toward the landward edge of the marsh relative to such associations as the *S. virginica*-Algae and the *Salicornia virginica-Frankenia salina-Suaeda taxifolia* Association. During low tides and in the hot summer months, this association regularly dries out and probably develops higher soil salinity than the adjacent regularly flooded tidal marsh. In some cases field crews were unable to determine the identity of *Salicornia* sp. in the samples, thus listing *Salicornia* sp. with *S. virginica*. Combined, these two taxa occurred in nearly 100% of the samples. Further, the field crews placed *Salicornia* in the shrub layer upon doing species cover and total shrub cover estimates, although many species in

this genus are traditionally considered perennial herbaceous vegetation (UCB 2004, NatureServe 2005).

Phases:
Salicornia virginica-Jaumea carnosa-Distichlis spicata (Pickleweed-Marsh Jaumea-Salt Grass) Phase [4527]
Distichlis spicata-Jaumea carnosa (Salt Grass-Marsh Jaumea) Phase [4514]

COMMON NAME	Salt Grass-Pickleweed-Marsh Jaumea-Herbaceous Association
FORMATION CLASS	V. Herbaceous vegetation
FORMATION SUBCLASS	V.A. Perennial graminoid vegetation
FORMATION GROUP	V.A.5. Temperate or subpolar grassland
FORMATION SUBGROUP	V.A.5.N. Natural/Seminatural temperate or subpolar grassland

Euphorbia terracina Herbaceous Stands

Geraldton Carnation Weed Herbaceous Stands

Mapping Code: 4771

Local Description

Summary:
Three herbaceous stands occur on gentle to somewhat steep slopes of variable aspect at low elevations between 5 and 48 m. It is dominated by *Euphorbia terracina* in the herbaceous layer, and *Brassica nigra* and *Bromus diandrus* are characteristically present at lower cover. *Ricinus communis* is often found in the shrub layer at low cover, and *Platanus racemosa* is often in the tree layer at low cover.

Distribution:
This vegetation type is sampled in the Immediate Coast region of the study area.

Environmental Description:
Elevation: range 5–48 m, mean 26 m
Aspect: variable
Slope: range 2–22 degrees, mean 9.7 degrees
Topography (micro; macro): variable; most often lower or bottom
Litter Cover: 40%
Small Rock Cover: range 0–10%, mean 5%
Large Rock Cover: no data
Bare Ground: range 20–35%, mean 27.5%
Parent Material: depositional
Soil Texture: moderately fine clay

Vegetation Description:
Stands of *Euphorbia terracina* form an intermittent to continuous herbaceous layer (50–80%, mean 65.3%) at 0.01–2 m tall. The shrub layer is sparse to open (0–1%, mean 0.7%) at 0.01–1 m tall. Trees are often emergent (0–5% cover, mean 2%) with hardwoods at 5–15 m tall. Total vegetation cover is 51–80%, mean cover is 67%.

The herbaceous layer is intermittent to continuous and is dominated by *Euphorbia terracina*, while *Brassica nigra* and *Bromus diandrus* are characteristically present at low cover. *Foeniculum vulgare, Silybum marianum*, and *Hordeum* sp. are usually included in this layer. The shrub layer is sparse and often includes *Ricinus communis*, but other shrubs such as *Myoporum laetum, Artemisia californica, Baccharis pilularis, Encelia californica, Sambucus mexicana*, and Opuntia sp. are sometimes present. The tree layer may include *Platanus racemosa* and may occasionally include *Quercus agrifolia* and *Juglans californica* as emergent trees.

Other Noteworthy Species:
Juglans californica was found in 1 of 3 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Euphorbia terracina, Brassica nigra, Bromus diandrus, Foeniculum vulgare, Ricinus communis, Silybum marianum, Bromus madritensis, Carpobrotus edulis, Melilotus indicus, Myoporum

laetum, Avena, Avena barbata, Bromus madritensis ssp. *rubens, Chenopodium ambrosioides, Erodium, Lolium multiflorum, Malva parviflora, Oxalis pes-caprae, Piptatherum miliaceum*

Samples Used in Description: (n = 3)
rap1006, rap1027, rap2535rlv

Comments:
Euphorbia terracina is a dangerously invasive nonnative species, which has taken over several coastal terraces and slopes near Malibu and other coastal areas of the Santa Monica Mountains. It tends to form such dense stands that it excludes other herbaceous species and probably native woody species. It is not considered extensive enough, nor sufficiently regionally established, to be considered an alliance yet.

Phases:
None

Foeniculum vulgare Herbaceous Alliance

Fennel Herbaceous Alliance

Mapping Code: 4760

Local Description

Summary:
This herbaceous alliance occurs on somewhat steep to flat slopes of variable aspect at low elevations between 140 and 178 m. It is dominated by *Foeniculum vulgare* in the herbaceous layer. *Baccharis pilularis* and *Rhus integrifolia* are often found in the shrub layer at low cover, and *Schinus molle* and *Juglans californica* are occasionally present in the tree layer at low cover.

Distribution:
This alliance is sampled in the Dry Inland and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 140–178 m, mean 160 m
Aspect: variable
Slope: range 15–15 degrees, mean 15 degrees
Topography (micro; macro): variable; lower to mid
Litter Cover: range 55–80%, mean 67.5%
Small Rock Cover: range 1–15%, mean 8%
Large Rock Cover: range 0–8%, mean 4%
Bare Ground: range 15–19%, mean 17%
Parent Material: igneous or depositional
Soil Texture: fine clay

Vegetation Description:
Stands of this herbaceous alliance form an open to continuous herbaceous layer (25–69%, mean 37.3%) at 0.5–5 m tall. The shrub layer is sparse to open (0–15%, mean 5.3%) at 0.5–5 m tall. Trees sometimes are emergent (0–2% cover, mean 0.8%) with hardwoods at 0–10 m tall. Total vegetation cover is 30–70%, mean cover is 43.5%.

In this alliance, the herbaceous layer is open to continuous and is dominated by *Foeniculum vulgare. Brassica nigra* and *Carduus pycnocephalus* are occasionally included in this layer. The shrub layer is open and frequently includes *Baccharis pilularis* and *Rhus integrifolia*. Occasionally, *Heteromeles arbutifolia, Malacothamnus fasciculatus, Mimulus aurantiacus,* and *Salvia leucophylla* are present in the shrub layer. The tree layer sometimes includes *Schinus molle* and *Juglans californica* as emergent trees.

Samples Used in Description: (n = 4)
AA0350cc, rap0120m, rap2248, rap2249

Comments:
Common fennel stands are now widespread in coastal central and southern California. They have caused concern on Santa Cruz Island (R. Klinger 1998, personal communication) because of the difficulty of removing them and being replaced by other weedy species. Stands have not been adequately sampled in any part of California to determine individual associations.

Phases:
None

Frankenia salina-Limonium californicum-Monanthochloe littoralis-Salicornia spp. Herbaceous Association

Alkali Heath-California Sea Lavender-Shore Grass-Pickleweed Herbaceous Association
***Frankenia salina* Herbaceous Alliance**
Alkali Heath Herbaceous Alliance

Mapping Code: 4551

Local Description

Summary:
This herbaceous association occurs on flat ground at low elevations between 1 and 3 m. *Monanthochloe littoralis* and *Distichlis spicata* are characteristically abundant and codominant with *Salicornia virginica* in the herbaceous layer. *Limonium californicum* is characteristically present and subdominant. *Frankenia salina* is characteristically found in the shrub layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: range 1–3 m, mean 1.8 m
Aspect: flat
Slope: no data
Topography (micro; macro): flat; bottom
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 10–10%, mean 10%
Parent Material: no data
Soil Texture: fine clay to sand

Vegetation Description:
Stands of the *Frankenia salina-Limonium californicum-Monanthochloe littoralis-Salicornia* spp. Herbaceous Association form an open to intermittent herbaceous layer (6–60%, mean 43.4%) at 0.01–0.5 m tall. The shrub layer is sparse to intermittent (0–47%, mean 13.2%) at 0–0.5 m tall. Total vegetation cover is 47–75%, mean cover is 56.6%.

In this association, the herbaceous layer is open to intermittent, and *Monanthochloe littoralis* and *Distichlis spicata* are characteristically present and codominant with *Salicornia virginica*. *Limonium californicum* is also characteristically present as a subdominant, and *Jaumea carnosa* is occasionally included in this layer. The shrub layer characteristically includes *Frankenia salina*, and it frequently includes *Suaeda taxifolia* and *Batis maritima*.

***Frankenia salina-Limonium californicum-Monanthochloe littoralis-Salicornia* spp. Association**

Other Noteworthy Species:
*Suaeda taxifolia (*synonym *S. californica* var. *taxifolia)* was found in 4 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G3?, and state rank is S2S3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
None

Samples Used in Description: (n = 5)
rap0866, rap0867m, rap0879, rap0880, rap0908

Comments:
This association has only been sampled from the study area, but it is likely to occur in other coastal salt marshes of southern California and adjacent Baja California, Mexico. It is closely related to several other coastal salt marsh associations in the *Salicornia virginica* Alliance. Further analysis of more sample data from other areas will be necessary to determine whether this association of the alkali heath alliance should remain a separate entity. The field crews placed *Salicornia* spp. in the shrub layer when doing species cover and total shrub cover estimates, although many species in this genus are traditionally considered perennial herbaceous vegetation (UCB 2004, NatureServe 2005).

Phases:
None

COMMON NAME Alkali Heath-California Sea Lavender-Shore Grass-Pickleweed Herbaceous Association

SYNONYM None

PHYSIOGNOMIC CLASS	V. Herbaceous vegetation

FORMATION	Intermittentently flooded perennial herbaceous vegetation
ALLIANCE	*Frankenia salina* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S2?

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
More northerly stands of the *Frankenia salina* Alliance have been sampled in Suisun Marsh (Solano County, California), but these stands did not have *Limonium californicum* or *Monanthochloe littoralis* associated with them. In general, stands dominated by *Frankenia salina* are less regularly flooded than stands of *Salicornia virginica* and occur on the outer margins of coastal marshes and other saline wetlands.

Juncus effusus Herbaceous Alliance

Common Rush Herbaceous Alliance

Mapping Code: 4330

Local Description

Summary:
One stand of this herbaceous vegetation occurs on a flat surface at low elevation (3 m). It is dominated by *Juncus effusus* in the herbaceous layer, with likely identification as *J. effusus* var. *brunneus* or *J. effusus* var. *pacificus.* Shrub species include *Myoporum laetum* and *Baccharis pilularis.* Emergent tree species include *Washingtonia* (introduced).

Distribution:
This alliance is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: 3 m
Aspect: flat/none
Slope: 0 degrees
Topography (micro; macro): flat; bottom
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: alluvium/dune
Soil Texture: sand

Vegetation Description:
One stand of the *Juncus effusus* Herbaceous Alliance forms an intermittent herbaceous layer (58%) at 0.5–1 m tall. The shrub layer is open (7%) at 0.5–2 m tall. Emergent trees are sparsely occurring (1%) with mainly hardwoods. Total vegetation cover is 65%.

In this alliance, the herbaceous layer is dominated by *Juncus,* likely *J. effusus* var. *brunneus* or *J. effusus* var. *pacificus.* Other graminoids and forbs occur in this layer at relatively low cover, including nonnative *Carpobrotus edulis.* The shrub layer is open, and *Myoporum laetum* and *Baccharis pilularis* exhibit low cover. The tree layer is sparse and includes *Washingtonia* (introduced).

ALLIANCE	*Juncus effusus* Herbaceous Stand
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains
CONSERVATION STATUS RANK	G4S4?

Global Description

Distribution:
Stands of various *Juncus* species occur in California including *Juncus mexicanus, J. balticus,* and *J. effusus. Juncus effusus* Alliance is found in most of the southeast states and elsewhere, although the full range in North America is incomplete. It is also found in the Pacific Northwest from British Columbia south to California. A *Juncus effusus* var. *brunneus* Association has been found within a few kilometers of the coast in the vicinity of the Point Reyes National Seashore as well as from the Puget Trough region of Washington and British Columbia. Also, a *J. effusus* Alliance with *J. e. pacificus* has been identified in inland San Diego County.

Nations:
United States, Canada

States or Provinces:
United States: AL, AR, CA, FL, GA, KY, LA, MS, NC, OK, SC, TN, TX, VA, WA and Canada, British Columbia. However, full distribution is not known in North America.

Environmental Description:
In Marin County, *Juncus effusus* var. *brunneus* Association was observed in small stands (under 2 ha.) in seasonally saturated soils within flats, depressions, or gentle slopes of all aspects. Stands prefer basins, bottoms, and plains, which are saturated during the rainy season and usually hold moist soils (sandy loams) most of the growing season. *Juncus effusus* stands are often able to persist in a degraded form in heavily grazed pastures where species associates are largely nonnative. In San Diego County, *Juncus effusus* var. *pacificus* stands occurred as small stands in artificially created stock ponds, riparian features, minor depressions/draws, and wet meadows/seeps. Across the country, J*uncus effusus* has a wide ecological amplitude, and additional alliances with different hydrologies may need to be defined. It is found in marsh habitats that vary greatly in size, situation, geographical location, species composition, and naturalness. Some are beaver-made or human-made impoundments.

Vegetation Description:
This alliance is currently broadly and literally defined, based on dominance by *Juncus effusus.* In Marin County, *Juncus effusus* var. *brunneus* has been found dominant, and other species at low cover may include *Potentilla anserina* var. *pacifica*, *Lolium perenne, Holcus lanatus*, *Trifolium wormskioldii, Trifolium repens*, *Equisetum telmateia braunii, Vicia sp* and/or *Vulpia* sp. In San Diego County, *Juncus effusus* var. *pacificus* was found dominant with *Urtica dioica*, while *Juncus mexicanus* and *Typha latifolia* are present in low cover. *Calocedrus decurrens* or *Salix* spp. are found as emergent trees. Across the country, associated species may include *Andropogon glomeratus, Cyperus* spp., *Typha latifolia, Scirpus cyperinus, Triadenum walteri, Apios americana*, and *Galium aparine*.

Comments:
Identification of the *Juncus* to subspecies is needed within the Santa Monica Mountains region before this alliance can be related to other *Juncus effusus* stands in the state and beyond.

Lepidium latifolium Herbaceous Association

Broad-Leaved Pepperweed Herbaceous Association
***Lepidium latifolium* Herbaceous Alliance**
Broad-Leaved Pepperweed Herbaceous Alliance

Mapping Code: 4780

Local Description

Summary:
One stand of this herbaceous association occurs on a gentle slope at low elevation (225 m). It is dominated by *Lepidium latifolium* in the herbaceous layer. Other herbs may also be present and are subdominant to low in cover such as *Hirschfeldia incana, Conium maculatum,* and *Bromus madritensis. Baccharis salicifolia* and *B. pilularis* are found in the shrub layer at low cover and, in the single sample, *Fraxinus velutina* and *Quercus lobata* are in the tree layer as sparse emergent trees.

Distribution:
This association is sampled in the Lower Elevation Inland Santa Monica Mountains region of the study area.

Environmental Description:
Elevation: 225 m
Aspect: variable
Slope: 2 degrees
Topography (micro; macro): undulating; bottom to lower
Litter Cover: 80%
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: depositional
Soil Texture: medium to very fine loamy sand

Vegetation Description:
One stand of *Lepidium latifolium* Herbaceous Association forms an intermittent herbaceous layer (54%) at 0.5–1 m tall. The shrub layer is sparse (1%) at 0–2 m tall. Trees are emergent (< 0.2%) with hardwoods at 5–10 m tall. Total vegetation cover is 63–63%, mean cover is 63%.

In this association, the herbaceous layer is intermittent and is dominated by *Lepidium latifolium. Hirschfeldia incana*, *Bromus madritensis, Conium maculatum*, and *Silybum marianum* are also included in this layer and may be subdominant to low in cover. The shrub layer includes *Baccharis salicifolia* and *B. pilularis* at low cover. The tree layer includes *Fraxinus velutina* and *Quercus lobata* as sparse emergent trees.

Other Noteworthy Species:
None

Nonnative Species:
Hirschfeldia incana, Bromus madritensis, Conium maculatum, Silybum marianum, Rumex crispus

Samples Used in Description: (n = 1)
rap2686

Comments:
These stands are made up of the dangerously invasive exotic weed *Lepidium latifolium*, which has proven very difficult to remove. Extensive stands can be found along Madea Creek and Paramount Ranch. These were not sampled because native vegetation is currently being restored and the *Lepidium* eradicated.

Phases:
None

COMMON NAME	Broad-Leaved Pepperweed Herbaceous Association
SYNONYM	None
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.B. Perennial forb vegetation
PHYSIOGNOMIC GROUP	V.B.2. Temperate or subpolar perennial forb vegetation
PHYSIOGNOMIC SUBGROUP	V.B.2.N. Natural/Seminatural
FORMATION	Intermittentently flooded perennial herbaceous vegetation
ALLIANCE	*Lepidium latifolium* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	None, this is an invasive weedy association.

Global Description

Distribution:
This vegetation type has not been identified as an alliance in the National Vegetation Classification System. According to the NRCS PLANTS database (http://plants.usda.gov/), it has been listed as a State Noxious Weed for 43 states.

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
Associations of *Lepidium latifolium* as well as *Salix gooddingii* and *Baccharis pilularis* alliances with high cover of *Lepidium latifolium* in the understory have been defined from San Diego County. They occur in riparian settings (e.g., San Dieguito River watershed). Other strongly herbaceous-dominated stands of *Lepidium latifolium* have been described from saline and brackish marshes of northern California.

Leymus condensatus Herbaceous Association

Giant Wild Rye Herbaceous Association
***Leymus condensatus* Herbaceous Alliance**
Giant Wild Rye Herbaceous Alliance

Mapping Code: 4041

Local Description

Summary:
This herbaceous association occurs on somewhat steep to steep often northerly slopes at low elevations between 25 and 503 m. It is dominated by *Leymus condensatus* in the herbaceous layer, though sometimes nonnative species can codominate with this native grass. *Salvia leucophylla* is usually found in the shrub layer at low cover, and *Juglans californica, Quercus agrifolia,* and *Sambucus mexicana* infrequently occur in the tree or tall shrub layer at low cover.

Distribution:
This association is sampled in the Dry Inland, Immediate Coast, Lower Elevation Inland Santa Monica Mountains, Upper Elevation Santa Monica Mountains, and Western Fog Zone regions of the study area.

Environmental Description:
Elevation: range 25–503 m, mean 352.1 m
Aspect: variable, but often northwest and northeast
Slope: range 15–38 degrees, mean 30 degrees
Topography (micro; macro): variable; variable, but often lower to mid
Litter Cover: range 25–75%, mean 50%
Small Rock Cover: range 0–15%, mean 6%
Large Rock Cover: range 0–2%, mean 0.5%
Bare Ground: range 5–55%, mean 22%
Parent Material: frequently sedimentary
Soil Texture: moderately fine silty clay loam

Vegetation Description:
Stands of the *Leymus condensatus* Herbaceous Association form an open to intermittent herbaceous layer (20–62%, mean 39.7%) at 0.01–2 m tall. The shrub layer is sparse to open though sometimes intermittent (0–35%, mean 8.6%) at 0–5 m tall. Trees are infrequently emergent (0–7% cover, mean 0.9%) with hardwoods at 0–10 m tall. Total vegetation cover is 30–65%, mean cover is 48.8%.

In this association, the herbaceous layer is open to intermittent and is dominated by *Leymus condensatus.* However, nonnative grasses and forbs may be present and subdominant to codominant. For example, nonnative *Brassica nigra* is often included in this layer. Nonnatives *Bromus diandrus* and *Avena fatua* occasionally occur, as does the native forb *Malacothrix saxatilis.* The shrub layer usually includes *Salvia leucophylla* and *Sambucus mexicana, Artemisia californica, Malacothamnus fasciculatus, Hazardia squarrosa,* and *Eriogonum cinereum* are occurring occasionally. The tree layer infrequently includes *Juglans californica, Quercus agrifolia,* and *Sambucus mexicana* as sparse emergent trees.

Comments:
This association is the first to be defined from this alliance. The alliance and this association tend to be short lived because they are stimulated by fire and are fairly quickly taken over by native shrubs of the coastal sage scrub zone following fire. Keeley 2002 has suggested that *Leymus condensatus* was one of the species whose abundance was maintained by Native American burning. In the SAMO mapping area, *Leymus* does occur after fires; however, it may persist

independently of fire in areas of human disturbance and urban runoff or in areas of coastal sage scrub where natural slumping and seepage occur.

Phases:
None

Leymus triticoides Herbaceous Alliance

Creeping Wild Rye Herbaceous Alliance

Mapping Code: 4030

Local Description

Summary:
Two stands of this herbaceous alliance occur on gentle to somewhat steep northeast and southeast slopes at low elevations between 224 and 305 m. They are dominated by *Leymus triticoides* in the herbaceous layer. *Baccharis pilularis, Baccharis salicifolia, Hazardia squarrosa,* and *Sambucus mexicana* are found in the shrub layer at low cover.

Distribution:
This association is sampled in the Dry Inland and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 224–305 m, mean 264.5 m
Aspect: northeast and southeast
Slope: range 2–20 degrees, mean 11 degrees
Topography (micro; macro): flat; lower
Litter Cover: range 30–90%, mean 60%
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: depositional
Soil Texture: fine silty clay

Vegetation Description:
Stands of this herbaceous alliance form a continuous herbaceous layer (75-80%, mean 77.5%) at 0.01-0.5 m tall. The shrub layer is sparse at 0-1 m tall. Total vegetation cover is 75-80%, mean cover is 77.5%.

In this alliance, the herbaceous layer is continuous and is dominated by *Leymus triticoides. Lactuca serriola* is frequently included in this layer at low cover. The shrub layer may include *Baccharis pilularis, Baccharis salicifolia, Hazardia squarrosa,* and *Sambucus mexicana* at sparse cover.

FORMATION	V.A.5.N.j. Temporarily flooded temperate or subpolar grassland
ALLIANCE	*Leymus triticoides* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S3

Global Description

Distribution:
This alliance is known from the Santa Monica Mountains as well as other parts of California including the Central Valley, central coast, and south coastal California (Evens and San 2004, Holland 1986, Holstein 2001, Keeler-Wolf and Vaghti 2000). It has been described from Oregon and Nevada as well (NatureServe 2005).

Nations:
United States

States or Provinces:
CA, OR, NV

Environmental Description:
Outside of California, this alliance is described from the Warner Valley of southeastern Oregon and the Cow Creek Basin on northwestern Nevada. Elevations range from 1,250–1,600 m. Climate is arid with mostly winter precipitation ranging from 10–25 cm annually. Stands occur in valleys in drainage bottoms, poorly drained floodplains, and historic lake basins. Sites are typically nearly flat but include moderate slopes (to 18%). It is found on the less xeric northeast and east aspects in Nevada. Soils are typically poorly drained, alkaline, with sandy loam to clay loam texture. The water table is shallow and causes mottles in the soil. Adjacent communities are shrublands dominated by *Artemisia tridentata*. Within California, this alliance occurs at elevations below 1,000 m on flat to moderate slopes of clay or loam soils where the climate is mediterranean (with cool wet winters and warm dry summers and precipitation ranging from 25 to 70 cm). Many stands may be relictual from preagricultural California, and nonnative grasses (or agriculture) probably have replaced many of the native stands. *Leymus triticoides* stands occur in open grassland habitats, drainage bottoms, floodplains, ravines/draws along coastal slopes, and so forth. Adjacent communities include other prairie or grassland habitats and oak savannas.

Vegetation Description:
As described in Oregon and Nevada, this vegetation occurs in bottomlands and lake basins. Stands have a moderate herbaceous layer (50–80% cover) codominated by the perennial graminoids *Elymus triticoides* with *Poa secunda* or *Carex* spp. Other frequent graminoid species include *Distichlis spicata, Hordeum californica, H. jubatum, Juncus balticus,* and forbs such as *Achillea millefolium, Agoseris glauca, Iris missouriensis, Scirpus* spp., *Triglochin maritima* and *Nitrophila occidentalis* in the saline/alkaline playas. In California, stands are equally high in cover and may be dominated by *Leymus triticoides* or codominated with annual grasses. Frequent

species include *Avena fatua, Bromus diandrus, B. hordeaceus, Carduus pycnocephalus, Distichlis spicata, Lactuca serriola, Lolium multiflorum,* and *Vulpia* spp.

Comments:
Stands of this vegetation in California have recently been described by Holstein 2001. This grassland was once much more widespread in the Central Valley prior to the development of low-lying lands for agriculture.

Evens and San 2004, Holland 1986, Holstein 2001, Keeler-Wolf and Vaghti 2000, NatureServe 2005

Lolium multiflorum Herbaceous Association

Italian Ryegrass Herbaceous Association
***Lolium multiflorum* Herbaceous Alliance**
Italian Ryegrass Herbaceous Alliance

Mapping Code: 4210

Local Description

Summary:
This herbaceous association occurs on flat to somewhat steep slopes of variable aspect at elevations between 208 and 270 m. It is dominated by *Lolium multiflorum* in the herbaceous layer. *Baccharis pilularis* is occasionally found in the shrub layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 208–270 m, mean 230.3 m
Aspect: usually flat
Slope: range 0–15 degrees, mean 4.6 degrees
Topography (micro; macro): usually flat or undulating; most often bottom or lower
Litter Cover: range 90–90%, mean 90%
Small Rock Cover: range 0–1%, mean 0.7%
Large Rock Cover: range 0–1%, mean 0.3%
Bare Ground: range 0–10%, mean 5.7%
Parent Material: depositional
Soil Texture: fine clay or silty clay

Vegetation Description:
Stands of the *Lolium multiflorum* Herbaceous Association form an intermittent to continuous herbaceous layer (40–90%, mean 66.4%) at 0.01–1 m tall. The shrub layer is sparse (0–1%, mean < 0.2%) at 0–2 m tall. Total vegetation cover is 40–90%, mean cover is 66.4%.

In this association, the herbaceous layer is dominated intermittently to continuously by *Lolium multiflorum*. A variety of other nonnative species also occur at low cover. For example, *Bromus diandrus* and *Brassica nigra* are often included in this layer, while *Avena fatua, Phalaris aquatica,* and *Bromus hordeaceus* sometimes occur. The shrub layer occasionally includes *Baccharis pilularis* at sparse cover.

rap0039, rap0065m, rap0068, rap1426, rap2529rlv, rap2530rlv, rap2849rlv

Comments:
This is a widespread and well-integrated nonnative graminoid vegetation alliance of much of California, and similar if not identical associations may occur throughout much of cismontane California below approximately 1,000 m elevation.

Phases:
None

COMMON NAME	Italian Ryegrass Herbaceous Association
SYNONYM	California Annual Grassland (Sawyer and Keeler-Wolf 1995), Nonnative Grassland (Holland 1986), *Bromus* (*diandrus, hordeaceus, madritensis*) Herbaceous Alliance (Reid et al. 1999)
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.D. Annual graminoid or forb vegetation
PHYSIOGNOMIC GROUP	V.D.2. Temperate or subpolar annual grasslands or forb vegetation
PHYSIOGNOMIC SUBGROUP	V.D.2.N. Natural/Seminatural
FORMATION	Short temperate annual grassland
ALLIANCE	*Lolium multiflorum* Herbaceous Alliance

CLASSIFICATION CONFIDENCE LEVEL 1

ECOLOGICAL REGIONS 261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains

CONSERVATION STATUS RANK G5S5—While *Lolium multiflorum* is now established in California as an invasive exotic grass alliance, certain stands may contain sensitive plant species and may have conservation value.

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. Although the pure *Lolium multiflorum* Association has been only defined here, it is likely to occur throughout much of cismontane California below approximately 1,000 m elevation in relatively low-lying areas that remain moist through much of the spring. It has only recently been separated from the broader California annual grassland alliance (Evens and San 2004, Evens et al. 2004, Keeler-Wolf and Vaghti 2000, Sawyer and Keeler-Wolf ms 2005).

Nations:
United States

States or Provinces:
CA

Environmental Description:
See local description.

Vegetation Description:
See local description.

Comments:
This alliance is likely to display a variety of associations in California. For example, it has been described on serpentine soils in central California (Santa Clara County), and another type has been defined in the Sierra Nevada foothills (Tuolumne County). Associations are also described from the margins of Suisun Marsh (Solano County).

References:
Evens and San 2004, Evens et al. 2004, Holland 1986, Keeler-Wolf and Vaghti 2000, Reid et al. 1999, Sawyer and Keeler-Wolf MS 2005, Sawyer and Keeler-Wolf 1995

Nassella lepida Herbaceous Alliance

Foothill Needlegrass Herbaceous Alliance

Mapping Code: 4090

Local Description

Summary:
One stand of this herbaceous alliance occurs on a moderately steep, southeast-facing slope at low elevation at 290 m. It is codominated by *Nassella lepida* and *Bromus hordeaceus* in the herbaceous layer. *Malosma laurina, Eriogonum cinereum, Rhus integrifolia,* and *Salvia leucophylla* are found in the shrub layer at low cover.

Distribution:
This alliance is sampled in the Immediate Coast region of the study area.

Environmental Description:
Elevation: 290 m
Aspect: southeast
Slope: 8 degrees
Topography (micro; macro): convex; upper to top
Litter Cover: no data
Small Rock Cover: 20%
Large Rock Cover: no data
Bare Ground: 28%
Parent Material: sedimentary
Soil Texture: no data

Vegetation Description:
One stand of this herbaceous alliance forms an intermittent herbaceous layer (41%) at 0.01–0.5 m tall. The shrub layer is 8% at 0.5–5 m tall. Total vegetation cover is 51%.

In this alliance, the herbaceous layer is intermittent and is codominated by *Nassella lepida* and *Bromus hordeaceus.* The shrub layer includes *Malosma laurina, Eriogonum cinereum, Rhus integrifolia,* and *Salvia leucophylla* at low cover.

Other Noteworthy Species:
None

Nonnative Species:
Bromus hordeaceus

Samples Used in Description: (n = 1)
rap0176

Comments:
Part of the problem in describing this alliance was in the uncertain identification of *Nassella* species (either *pulchra* or *lepida*) due to sampling at nonflowering or fruiting seasons. This alliance appears to occur only rarely in the study area, and it may locally dominate following fire. The species is usually accompanied by relatively high cover of coastal scrub species. Such stands are considered shrublands.

Phases:

Global Description

Distribution:
This alliance occurs in northern, central, and southern cismontane California.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This bunchgrass alliance of California's valleys and foothills grows on deep soils with high clay content, often derived from sandstone or ultramafic parent material. Stands can occur on all topographic positions. However, because of climatic factors, they do not occur in more than 1,700 m elevation. The native California bunchgrasses are adapted to a mediterranean climate with moist, cool winters and long, dry summers. Precipitation varies from 25 and 70 cm per year and falls mostly between November and April. Stands typically include many nonnative annual grasses and herbs.

Vegetation Description:
This native grass forms a medium to tall bunch temperate or subpolar grassland with an open canopy less than 1 m in height. Emergent trees and shrubs may be present. This California native bunchgrass alliance is dominated by *Nassella lepida*. Other graminoids present may include *Festuca californica, Melica californica, Nassella pulchra, Nassella cernua, Calamagrostis koelerioides*, and *Poa secunda*. Many nonnative annuals, such as *Bromus hordeaceus and B. diandrus*, have invaded stands of this alliance. On sites with ultramafic-derived soils, serpentine-adapted species may be present.

Comments:
Stands of this and other central and southern California coastal native grassland alliances may have been maintained by Native American burning (Sawyer and Keeler-Wolf 1995, Keeley 2002).

Sawyer and Keeler-Wolf 1995, Keeley 2002

Nassella pulchra Herbaceous Alliance

Purple Needlegrass Herbaceous Alliance

Mapping Code: 4020

Although most samples of this widespread cismontane California alliance fell into one specific local association that is described in the following text, five samples did not and will be briefly described here. These five stands are found on fine to moderately fine silty clay loam and range from flat to moderately steep slopes. In general, the stands of *Nassella pulchra* grassland are small and are typically associated with shrublands immediately adjacent to them. Unlike *Nassella lepida*, *N. pulchra* does not commonly occur in the understory of coastal scrub communities dominated by *Salvia* spp. or *Artemisia californica*. *Nassella pulchra* does associate with the early seral shrubs, *Baccharis pilularis* and *Hazardia squarrosa,* where these shrubs usually are colonizing grass-dominated stands. The most constant and abundant members of these five stands, aside from *Nassella pulchra*, are *Bromus diandrus* and *Avena fatua*.

This once extensive bunchgrass alliance of California's valleys and foothills grows on deep soils with high clay content (Holland 1986, Sawyer and Keeler-Wolf 1995). Stands can occur on all topographic positions. However, because of climatic factors, they do not occur in more than 1,300 m elevation. The native California and Baja California bunchgrass is adapted to a mediterranean climate with moist, cool winters and long, dry summers. Precipitation varies from 25 to 70 cm per year and falls mostly between November and April. Grazing and fire are important in maintaining the grassland communities, though uncertainty still exists concerning the optimum grazing type and intensity. Stands now typically include many nonnative annual grasses, and reduction in fire frequency has probably favored introduced annual grasses over native perennial bunchgrasses.

This native grass forms a medium to tall bunch temperate or subpolar grassland with an open canopy less than 1 m in height. Emergent trees and shrubs may be present. The alliance is dominated by *Nassella pulchra*, or the native grass cover is at least 10–15% relative to the nonnative grass cover. Other graminoids present may include *Elymus glaucus, Festuca californica, Melica californica, Nassella lepida, N. cernua, Melica imperfecta, Koeleria macrantha*, and *Poa secunda*. Many nonnative annuals, such as *Bromus diandrus, B. madritensis, B. hordeaceus, Avena barbata, A. fatua*, and *Lolium multiflorum*, have invaded stands of this alliance.

Nassella pulchra-Hazardia squarrosa Herbaceous Association

Purple Needlegrass-Sawtooth Goldenbush Herbaceous Association
***Nassella pulchra* Herbaceous Alliance**
Purple Needlegrass Herbaceous Alliance

Mapping Code: 4021

Local Description

Summary:
This herbaceous association occurs on gentle to steep often northeast or northwest slopes at low elevations between 52 and 422 m. *Nassella pulchra* is characteristically abundant in the herbaceous layer. *Hazardia squarrosa* is characteristically found in the shrub layer at low cover, and *Artemisia californica* is also usually present in this layer.

Distribution:
This association is sampled in the Immediate Coast, Western Fog Zone, Dry Inland, and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 52–422 m, mean 172 m
Aspect: variable, often northeast or northwest
Slope: range 2–35 degrees, mean 13.4 degrees
Topography (micro; macro): usually flat; variable, but often mid to upper
Litter Cover: range 15–85%, mean 50.3%
Small Rock Cover: range 0–23%, mean 5.8%
Large Rock Cover: no data
Bare Ground: range 2–36%, mean 19.6%
Parent Material: frequently sedimentary
Soil Texture: usually fine to moderately fine clay

Vegetation Description:
Stands of the *Nassella pulchra-Hazardia squarrosa* Herbaceous Association form an open to intermittent herbaceous layer (19–55%, mean 39.5%) at 0.01–1 m tall. The shrub layer is sparse to open (0–13%, mean 5%) at 0.01–2 m tall. Total vegetation cover is 28–58%, mean cover is 44.4%.

In this association, the herbaceous layer is open to intermittent, and *Nassella pulchra* is characteristically abundant. A variety of other herbaceous species occurs, and they may be subdominant. For example, *Avena fatua* is often present, and *Calochortus catalinae*, *Sisyrinchium bellum*, *Hemizonia fasciculate*, *Bromus madritensis*, *Bromus hordeaceus*, *Brassica nigra*, and *Erodium cicutarium* are sometimes found in this layer. The shrub layer characteristically includes *Hazardia squarrosa* and often includes *Artemisia californica* at low cover.

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Dichondra occidentalis was found in 1 of 13 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G4?, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Dudleya blochmaniae was found in 1 of 13 surveys of this plant community, which may be the rare *Dudleya blochmaniae* subsp. *blochmaniae.* Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and CNPS R-E-D Code is 2-3-2. Global rank is G2T2, and state rank is S2.1. Federal listing is Species of Concern, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Avena fatua, Bromus madritensis, Bromus hordeaceus, Brassica nigra, Erodium cicutarium, Bromus diandrus, Anagallis arvensis, Foeniculum vulgare, Medicago polymorpha, Sonchus

oleraceus, Hirschfeldia incana, Silene gallica, Avena, Avena barbata, Erodium moschatum, Euphorbia terracina, Vicia villosa, Erodium, Galium aparine, Lactuca serriola, Lolium multiflorum, Marrubium vulgare, Melilotus indicus, Phalaris aquatica, Senecio vulgaris, Silybum marianum, Sonchus asper

Samples Used in Description: (n = 13)

Comments:
This is the most common native grassland in the study area and the primary representative of the widespread *Nassella pulchra* Alliance (Sawyer and Keeler-Wolf 1995). It shows a transitional and seral nature to scrubland by the constant presence of *Hazardia squarrosa*, a common early seral perennial subshrub of coastal southern California. Further, *Hazardia squarrosa/Nassella pulchra-Hemizonia fasciculata* Shrubland Association is also defined in the study area where the shrub layer is more developed. It would be useful to monitor several of these local stands with different fire histories to gain a better understanding of the persistence of this association under different fire regimes and soil types.

Phases:
None

Pennisetum setaceum Herbaceous Alliance

Fountain Grass Herbaceous Alliance

Mapping Code: 4060

Three samples of this dangerously invasive nonnative alliance were classified to the alliance level only and will be briefly described here. These occurred on steep southerly facing slopes in the eastern urban, immediate coastal, and Simi Hills regions of the park in similar settings to the described *Pennisetum* Association to follow.

The nonnative (African) fountain grass alliance tends to form monospecific stands although it may also have a number of emergent native or nonnative woody species such as *Rhus integrifolia, R. ovata, Artemisia californica, Encelia californica, Eriogonum fasciculatum,* or *E. cinereum* associated with the stands.

This is the first study in which this alliance has been identified in California. However, it is well understood to be commonly occurring as an invasive grassland along sea cliffs and road cuts from San Diego County to Santa Barbara County and has been noted inland as far as Anza-Borrego Desert State Park in San Diego County.

The alliance appears to be dangerously invasive (Bossard et al. 2000) and was initially established as ornamental plantings but has now begun colonizing cliffs and other steep slopes away from direct human disturbance such as road embankments. One association has already been defined in this study of the Santa Monica Mountains.

Samples classified to the alliance level only: (n = 3)

Pennisetum setaceum-Coreopsis gigantea-Yucca whipplei-Malosma laurina Herbaceous Association

Fountain Grass-Giant Coreopsis-Chaparral Yucca Herbaceous Association
***Pennisetum setaceum* Herbaceous Alliance**
Fountain Grass Herbaceous Alliance

Mapping Code: 4061

Local Description

Summary:
This herbaceous association occurs on flat to very steep, often southerly facing slopes at low elevations between 0 and 36 m. It is dominated solely by *Pennisetum setaceum* in the herbaceous layer. *Malosma laurina, Eriogonum cinereum,* and *Yucca whipplei* are characteristically found in the shrub layer at low cover, and *Washingtonia* sp. is infrequently in the tree layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 0–36 m, mean 12 m
Aspect: variable, but often southeast or southwest
Slope: range 0–60 degrees, mean 40.7 degrees
Topography (micro; macro): undulating or flat; variable, but often bottom to lower
Litter Cover: range 15–15%, mean 15%
Small Rock Cover: range 10–40%, mean 23.3%
Large Rock Cover: range 5–15%, mean 9.7%
Bare Ground: range 15–50%, mean 35%
Parent Material: igneous
Soil Texture: sand (class unknown) or medium loam

Vegetation Description:
Stands of the *Pennisetum setaceum-Coreopsis gigantea-Yucca whipplei-Malosma laurina* Herbaceous Association form an open to intermittent herbaceous layer (22–40%, mean 32.1%) at 0.01–1 m tall. The shrub layer is open (2–14%, mean 8.9%) at 0.01–5 m tall. Total vegetation cover is 30–49%, mean cover is 40.3%.

In this association, the herbaceous layer is open to intermittent and is dominated solely by *Pennisetum setaceum*. *Brassica nigra, Foeniculum vulgare, Carpobrotus edulis, Bromus madritensis, Malacothrix saxatilis,* and *Medicago polymorpha* are occasionally included in this layer at sparse cover. The shrub layer characteristically includes *Malosma laurina, Eriogonum cinereum,* and *Yucca whipplei* and also usually includes *Salvia mellifera, Coreopsis gigantea*, and *Rhus integrifolia*. The tree layer infrequently includes *Washingtonia* sp. (introduced) as an emergent.

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 7 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Pennisetum setaceum, Brassica nigra, Foeniculum vulgare, Carpobrotus edulis, Bromus madritensis, Medicago polymorpha, Melilotus, Avena barbata, Avena fatua, Bromus hordeaceus, Erodium, Euphorbia terracina, Malva parviflora, Melilotus indicus, Nicotiana glauca, Ricinus communis, Sonchus oleraceus

Samples Used in Description: (n = 7)
rap0512, rap0670, rap0882, rap1138, rap1197m, rap1203, rap2897rlv

Comments:
This is the first association defined from this nonnative alliance in California. It is the most typical expression of the alliance in the Santa Monica Mountains, found on steep coastal cliffs, bluffs, and road cuts, immediately adjacent to the Pacific Ocean; it has also been found on sand dunes along the immediate coast. *Pennisetum setaceum* is a dangerously invasive nonnative grass.

Phases:
None

COMMON NAME	Fountain Grass-Giant Coreopsis-Chaparral Yucca Herbaceous Association
SYNONYM	None
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.A. Perennial graminoid vegetation
PHYSIOGNOMIC GROUP	V.A.5. Temperate or subpolar grassland
PHYSIOGNOMIC SUBGROUP	V.A.5.N. Natural/Seminatural temperate or subpolar grassland
FORMATION	V.A.5.N.d. Medium-Tall bunch temperate or subpolar grassland
ALLIANCE	*Pennisetum setaceum* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	None, this is a nonnative alliance. However, it may have some conservation value if localized or rare native species are associated with it. As this association increases throughout southern California, fewer and fewer natural coastal bluff and cliff communities will remain.

Global Description

Distribution:
This association is only known from the Santa Monica Mountains region. Information about its global distribution is not available without additional inventory. However, it is well understood to be commonly invasive along sea cliffs and road cuts from San Diego County to Santa Barbara County and has been noted inland as far as Anza-Borrego Desert State Park in San Diego County (Bossard et al. 2000). It has escaped from plantings (e.g., San Diego Wild Animal Park) and is now becoming a significant invasive.

Phalaris aquatica Herbaceous Alliance

Harding Grass Herbaceous Alliance

Mapping Code: 4070

Local Description

Summary:
This herbaceous alliance occurs on flat to moderately steep slopes of variable aspect at low elevations between 188 and 228 m. It is dominated by *Phalaris aquatica* in the herbaceous layer. *Baccharis pilularis* is sometimes found in the shrub layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone and Upper Elevation Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 188–228 m, mean 205 m
Aspect: variable
Slope: range 0–9 degrees, mean 3.7 degrees
Topography (micro; macro): flat; bottom to lower
Litter Cover: range 55–95%, mean 80%
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 0–10%, mean 5%
Parent Material: igneous
Soil Texture: fine to moderately fine sandy or silty clay loam

Vegetation Description:
Stands of this herbaceous alliance form an open to continuous herbaceous layer (25–77%, mean 49%) at 0.1–1 m tall. The shrub layer is sparse to open (0–5%, mean 1.3%) at 0–0.5 m tall. Total vegetation cover is 25–70%, mean cover is 48.7%.

In this alliance, the herbaceous layer is open to continuous and is dominated by *Phalaris aquatica*. *Avena fatua* is occasionally included in this layer, and a variety of other herbs, such as *Bromus diandrus*, *Sisyrinchium bellum*, and *Melilotus indicus,* are infrequently present. The shrub layer occasionally includes *Baccharis pilularis,* and other shrubs may occur infrequently.

Phalaris aquatica Alliance

	AVFA	*Avena fatua*	33	0.4	0.2	2.0			X

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 6 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and the CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Phalaris aquatica, Avena fatua, Bromus diandrus, Melilotus indicus, Bromus hordeaceus, Bromus madritensis, Lolium multiflorum, Anagallis arvensis, Brassica, Euphorbia terracina, Foeniculum vulgare, Picris echioides

Samples Used in Description: (n = 6)
rap0040, rap0052m, rap0085, rap2531rlv, rap2894rlv, rap2895rlv

Comments:
In the Santa Monica Mountains, this vegetation alliance tends to favor moist low areas of grasslands including those with seasonally saturated soil. It seems to be found in areas that had experienced heavy grazing in the past.

Phases:
None

COMMON NAME	Harding Grass Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.A. Perennial graminoid vegetation
PHYSIOGNOMIC GROUP	V.A.5. Temperate or subpolar grassland
PHYSIOGNOMIC SUBGROUP	V.A.5.N. Natural/Seminatural
FORMATION	V.A.5.N.d. Medium-Tall bunch temperate or subpolar grassland
ALLIANCE	*Phalaris aquatica* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains
CONSERVATION STATUS RANK	None, introduced invasive exotic

Global Description

Distribution:
This alliance is not well sampled in California. However, it has been reported from several areas of coastal northern and central California including Colusa/Glen, Marin, Santa Clara, and Solano counties.

Nations:
United States

States or Provinces:
CA

Environmental Description:
The alliance has been introduced into California, while it is native to the Mediterranean region of Europe. In California, it has been found in inland sites below 800 m in elevation on gentle to moderately steep slopes with a thick layer and high surface cover of litter. Parent material is quite variable including volcanic, Fransciscan, serpentine, and alluvial, and soil is variable from coarse sandy loam to fine silty clay. It has been found in a variety of disturbed habitats including along levees in Suisun Marsh, upper slopes that were converted from chaparral vegetation in the north coast range, disturbed upper grassland slopes in central California, and so forth.

Vegetation Description:
This alliance is defined by *Phalaris aquatica* as the indicator species, with *P. aquatica* dominant or codominant with other nonnative species. One association has been described with *P. aquatica* co-occurring with *Bromus hordeaceus* and *Centaurea solstitialis* from the southern portion of the north coast ranges of California. Other species include annual forbs such as *Clarkia* sp.*, Galium* sp.*, Erodium* sp., *Trifolium dubium,* and *Yabea microcarpa.* A pure association of *P. aquatica* has been defined from Suisun Marsh in small stands along levees. An association of *P. aquatica* dominant to codominant with *Avena barbata* also occurs in the central coast south of San Jose, and characteristic species at low cover include *Lolium multiflorum, Bromus hordeaceus,* and *Erodium* sp. In southern California, *P. aquatica* has been found dominant, and *Avena fatua* was characteristic at low cover.

Comments:
This is aggressively invasive as nonnative grassland forming dense clumps in typically low-lying areas or disturbed areas (Bossard et al. 2000, Evens and San 2004, Jimerson et al. 2000, NatureServe et al. 2003a, Keeler-Wolf and Vaghti 2000). It is favored by frequent fire or clearing, and it appears to colonize and expand in areas formerly dominated by annual grassland, native *Nassella* grassland, or chaparral.

Bossard et al. 2000, Evens and San 2004, Jimerson et al. 2000, NatureServe et al. 2003a, Keeler-Wolf and Vaghti 2000

Salicornia virginica/Algae Herbaceous Association

Pickelweed/Algae Herbaceous Association
***Salicornia virginica* Herbaceous Alliance**
Pickleweed Herbaceous Alliance

Mapping Code: 4528

Local Description

Summary:
This herbaceous association occurs on flat ground at low elevations between 1 and 3 m. It is dominated by algae in the herbaceous layer, and *Salicornia virginica* is characteristically found as a subdominant to codominant.

Distribution:
This association is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: range 1–3 m, mean 2 m
Aspect: flat
Slope: flat
Topography (micro; macro): flat; bottom
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 40–90%, mean 71.7%
Parent Material: no data
Soil Texture: sand to clay

Vegetation Description:
Stands of the *Salicornia virginica*/Algae Herbaceous Association form an open to intermittent herbaceous layer (15–56%, mean 36.6%) at 0.01–0.5 m tall. The shrub layer is sparse to open (0–8%, mean 1.6%) at 0–0.5 m tall. Total vegetation cover is 15–56%, mean cover is 37.8%.

In this association, the herbaceous layer is open to intermittent and is dominated by algae, while *Salicornia virginica* is characteristically abundant and subdominant to codominant. *Salicornia bigelovii* and *Triglochin concinnum* are infrequently included in this layer at low cover. *Suaeda taxifolia* and *Frankenia salina* are infrequently present at low cover in the shrub layer.

Other Noteworthy Species:
*Suaeda taxifolia (*synonym *S. californica* var. *taxifolia)* was found in 1 of 5 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G3?, and state rank is S2S3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
None

Samples Used in Description: (n = 5)
rap0865, rap0870, rap0873, rap0875, rap2700

Comments:
This is the more open expression of pickleweed marsh in Mugu Lagoon within the study area and seems to be found in some of the wettest portions of the marsh. It is unclear which species of the algae is (are) present, and it is also unclear how ecologically different this association is from other similar local *Salicornia* associations. There is the possibility that with further detailed analysis of nonvascular flora, this association could be lumped with others of the same alliance. At this point these stands are classified here because of their generally less dense cover of *S. virginica* and the presence of algal mats, which are visible at low tide. The field crews placed *Salicornia* spp. in the shrub layer when doing species cover and total shrub cover estimates, although many species in this genus are traditionally considered perennial herbaceous vegetation (UCB 2004, NatureServe 2005).

Phases:
None

COMMON NAME	Pickelweed/Algae Herbaceous Association

Salicornia virginica-Brassica nigra Herbaceous Association

Pickleweed-Black Mustard Herbaceous Association
***Salicornia virginica* Herbaceous Alliance**
Pickleweed Herbaceous Alliance

Mapping Code: 4529

Local Description

Summary:
This herbaceous association occurs on flat to gentle slopes of variable aspect at low elevations between 0 and 5 m. *Brassica nigra* is characteristically abundant in the herbaceous layer. *Salicornia virginica* is characteristically abundant in the shrub layer, and *Frankenia salina* is also often present at low cover in this layer.

Distribution:
This association is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: range 0–5 m, mean 2 m
Aspect: frequently flat
Slope: range 0–2 degrees, mean 0.7 degrees
Topography (micro; macro): flat; bottom
Litter Cover: range 65–65%, mean 65%
Small Rock Cover: range 0–1%, mean 0.3%
Large Rock Cover: no data
Bare Ground: range 20–55%, mean 41.7%
Parent Material: no data
Soil Texture: moderately fine sandy to silty clay loam

Vegetation Description:
Stands of the *Salicornia virginica-Brassica nigra* Herbaceous Association form an open to intermittent herbaceous layer (13–42%, mean 29.7%) at 0.01–1 m tall. The shrub layer is sparse to open (0–24%, mean 8.7%) at 0–5 m tall. Total vegetation cover is 30–43%, mean cover is 38.3%.

In this association, the herbaceous layer is open to intermittent with *Salicornia virginica* dominant, and *Brassica nigra* is characteristically subdominant to codominant. *Polypogon monspeliensis*, *Raphanus sativus*, *Carpobrotus edulis, Melilotus albus, Bromus madritensis*, and *Galium aparine* are occasionally included in this layer. *Frankenia salina*, *Atriplex lentiformis, Baccharis pilularis,* and *Myoporum laetum* are often present in the shrub layer and usually at low cover.

Samples Used in Description: (n = 6)
rap0898, rap0900, rap2710, rap2711, rap2712, rap2778

Comments:
This association represents the local expression of the coastal salt marsh edge, where adjacent weedy herbaceous vegetation borders upon it (Zedler 1982). The marsh edge position of this association is also indicated by the presence of several typically upland shrubby species such as *Atriplex lentiformis, Baccharis pilularis, and Opuntia oricola*. It is likely that such weedy marginal associations occur in other southern California coastal salt marshes and would be recognized with local stand level sampling. The field crews placed *Salicornia* spp. in the shrub layer when doing species cover and total shrub cover estimates, although many species in this genus are traditionally considered perennial herbaceous vegetation (UCB 2004, NatureServe 2005).

Phases:
None

*Salicornia virginica-Frankenia salina-Suaeda taxifolia (*synonym *Suaeda californica* var. *taxifolia)* Herbaceous Association

Pickleweed-Alkali Heath-Sea Blite Herbaceous Association
***Salicornia virginica* Herbaceous Alliance**
Pickleweed Herbaceous Alliance

Mapping Code: 4524

Local Description

Summary:
This herbaceous association occurs on flat to gently sloped ground at low elevations between 0 and 6 m. *Salicornia virginica* is characteristically abundant and dominant in the herbaceous layer, while *Frankenia salina* and *Suaeda taxifolia* are characteristically found in the shrub layer at low cover.

Distribution:
This association is sampled in the Western Fog Zone region of the study area.

Environmental Description:
Elevation: range 0–6 m, mean 2 m
Aspect: flat
Slope: 0–2 degrees mean 0.3 degrees
Topography (micro; macro): flat; bottom
Litter Cover: range 30–30%, mean 30%
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 20–90%, mean 53.3%
Parent Material: no data
Soil Texture: sand to clay

Vegetation Description:
Stands of the *Salicornia virginica-Frankenia salina-Suaeda taxifolia* Herbaceous Association form an open to intermittent herbaceous layer (1–65%, mean 35.9%) at 0.01–0.5 m tall. The shrub layer is sparse to continuous (0–67%, mean 11.1%) at 0–1 m tall. Total vegetation cover is 13–70%, mean cover is 47%.

In this association, the herbaceous layer is open to intermittent and is dominated by *Salicornia virginica.* It also occasionally contains *Distichlis spicata, Triglochin concinnum*, and *Limonium californicum* at low cover. The shrub layer characteristically includes *Frankenia salina* and *Suaeda taxifolia* at low cover.

***Salicornia virginica-Frankenia salina-Suaeda taxifolia* Association**

Other Noteworthy Species:
Abronia maritima was found in 1 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-2. Global rank is G4?, and state rank is S3?. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

*Suaeda taxifolia (*synonym *S. californica* var. *taxifolia)* was found in 14 of 18 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G3?, and state rank is S2S3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Arundo donax, Bromus madritensis, Melilotus indicus, Brassica, Mesembryanthemum nodiflorum, Myoporum laetum, Rumex crispus, Sonchus

Samples Used in Description: (n = 18)
rap0868, rap0874m, rap0878, rap0881, rap0905, rap0906, rap0909, rap2698, rap2699, rap2701, rap2702, rap2704, rap2705, rap2706, rap2708, rap2774, rap2775, rap2776

Comments:
This association is probably the most extensive of this *Salicornia* Alliance locally. It was found to have significant variability ranging from stands strongly dominated by *S. virginica* to stands with little cover of this species to stands with codominance of the three nominate species. The field crews placed *Salicornia* in the shrub layer upon doing species cover and total shrub cover estimates, although many species in this genus are traditionally considered perennial herbaceous vegetation (UCB 2004, NatureServe 2005).

Both *Frankenia salina* and *Suaeda taxifolia* occurred in about 80–90% of the stands averaging 1 to 5% cover, while *Distichlis spicata* occurred in less than 40% of the stands, thus separating this association from the *Distichlis spicata-Salicornia virginica-Jaumea carnosa* Herbaceous Association. It does not contain marsh edge species as does the *S. virginica-Brassica nigra* Association. The presence of *Batis maritima* in > 50% of the samples suggests that this is a core marsh association with less dry periods than those associations with high frequencies of *Distichlis spicata.*

Phases:
Salicornia virginica-Frankenia salina-Batis maritima (Pickleweed-Alkali Heath-Saltwort) Phase [4526]
Salicornia virginica-Suaeda taxifolia (Pickleweed-California Sea Blite) Phase [45201]
Salicornia virginica-Frankenia salina-Suaeda taxifolia (Pickleweed-Alkali Heath-California Sea Blite [Provisional]) Phase [4524]

Salicornia virginica-Salicornia subterminalis Herbaceous Association

Pickleweed-Parish's Glasswort Herbaceous Association
***Salicornia virginica* Herbaceous Alliance**
Pickleweed Herbaceous Alliance

Mapping Code: 4525

Local Description

Summary:
This herbaceous association occurs on flat ground at low elevations between 0 and 3 m. *Salicornia subterminalis* and *Salicornia virginica* are characteristically abundant in the herbaceous layer, and *Brassica nigra* is characteristically present at low cover.

Distribution:
This association is sampled in the Western Fog Zone and Immediate Coast regions of the study area.

Environmental Description:
Elevation: range 0–3 m, mean 2 m
Aspect: flat
Slope: no data
Topography (micro; macro): flat; bottom
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 60–60%, mean 60%
Parent Material: no data
Soil Texture: fine to moderately fine silty clay

Vegetation Description:
Stands of the *Salicornia virginica-Salicornia subterminalis* Herbaceous Association form an open herbaceous layer (4–22%, mean 12.3%) at 0.01–0.5 m tall. The shrub layer is sparse to open (0–26%, mean 6.5%) at 0–1 m tall. Total vegetation cover is 10–30%, mean cover is 18.8%.

In this association, the herbaceous layer is open with *Salicornia subterminalis* and *Salicornia virginica* characteristically abundant and codominant. Sometimes *S. subterminalis* can dominate and *S. virginica* subdominate. *Brassica nigra* is characteristically present at low cover, and *Mesembryanthemum nodiflorum* is often present. *Frankenia salina, Batis maritima, Atriplex lentiformis*, and *Suaeda taxifolia* are also occasionally found in the shrub layer.

***Salicornia virginica-Salicornia subterminalis* Association**

Other Noteworthy Species:
*Suaeda taxifolia (*synonym *S. californica* var. *taxifolia)* was found in 1 of 4 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-1. Global rank is G3?, and state rank is S2S3. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Brassica nigra, Mesembryanthemum nodiflorum, Bromus diandrus, Carpobrotus chilensis, Galium aparine, Lactuca serriola, Melilotus albus

Samples Used in Description: (n = 4)
rap0877, rap0901, rap2703, rap2709

Comments:
Crews observed this association in areas where salt deposits accumulate into salt pans. The field crews placed the two *Salicornia* spp. in the shrub layer upon doing species cover and total shrub cover estimates, although these species in this genus are traditionally considered perennial herbaceous vegetation (UCB 2004, NatureServe 2005).

This provisional association is very closely related to the *Salicornia virginica-Brassica nigra* Association, differing only in the higher frequency of the regional salt marsh indicator *Salicornia subterminalis.* However, this association mixed *Salicornia* is also found in the San Dieguito Lagoon, where *Salicornia subterminalis* is subdominant to codominant with *S. virginica.*

Phases:
None. However, this is potentially a phase of the *Salicornia virginica-Brassica nigra* Association.

COMMON NAME	Pickleweed-Parish's Glasswort Herbaceous Association
SYNONYM	Coastal Salt and Brackish Marsh (Holland 1986)
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.B. Perennial forb vegetation
PHYSIOGNOMIC GROUP	V.B.2. Temperate or subpolar perennial forb vegetation
PHYSIOGNOMIC SUBGROUP	V.B.2.N. Natural/Seminatural
FORMATION	Intermittentently flooded perennial herbaceous vegetation
ALLIANCE	*Salicornia virginica* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	2
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G3S3

Global Description

Distribution:
This association has been found in coastal salt marshes in southern California including Ventura and San Diego counties (Evens and San 2005, Zedler 1982).

Nations:
United States

States or Provinces:
CA

Environmental Description:
This association has been observed in coastal salt marshes with silty clay or silty loam alluvial soils, while being mucky, and where salt deposits have accumulated. They are on flat to gentle bottoms such as lagoons. Litter and fine sediments are the prevalent ground surface.

Vegetation Description:
Salicornia virginica codominates with *Salicornia subterminalis*, while sometimes either *Salicornia* species is subdominant. Other species may occur at low cover including *Frankenia salina, Atriplex lentiformis, Mesembryanthemum* spp., *Carpobrotus chilensis, Bromus diandrus, Distichlis spicata*, and *Isocoma menziesii.*

Comments:
Additional sampling is needed to further verify this association's distribution and variation.

Evens and San 2005, Holland 1986, Zedler 1982

Scirpus acutus-Scirpus californicus Herbaceous Alliance

California Bulrush Herbaceous Alliance

Mapping Code: 4410

Local Description

Summary:
Three stands of this herbaceous alliance occur on flat to gentle slopes at low elevations between 0 and 414 m. *Scirpus californicus* and/or *S. acutus* are characteristically abundant in the herbaceous layer. *Salix lasiolepis* is often found in the shrub layer at low cover.

Distribution:
This alliance is sampled in the Immediate Coast region of the study area.

Environmental Description:
Elevation: range 0–414 m, mean 139.3 m
Aspect: variable to flat
Slope: 0–2 degrees
Topography (micro; macro): flat; bottom
Litter Cover: no data
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: range 15–15%, mean 15%
Parent Material: depositional
Soil Texture: sand (class unknown)

Vegetation Description:
Stands of this herbaceous alliance form an intermittent to continuous herbaceous layer (48–70%, mean 61%) at 1–5 m tall. Total vegetation cover is 48–70%, mean cover is 61%.

In this alliance, *Scirpus californicus* and/or *S. acutus* may be abundant in the herbaceous layer. In the three stands sampled, *S. californicus* is characteristic and most abundant. Other herbs, such as *Distichlis spicata*, *Juncus* sp., and *Typha* sp., are sometimes present. The shrub layer often includes *Salix lasiolepis*.

CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:

This *Scirpus acutus-S. californicus* Alliance is found in the midwest region (Nebraska, Iowa, South Dakota, North Dakota, and Minnesota), in the western region (California, Oregon, Washington, Idaho, and Montana), and in Canada (British Columbia, southern Manitoba, and northwestern Ontario).

Nations:
United States, Canada, Mexico

States or Provinces:
USA: NE, IA, SD, ND, MN, CA, OR, WA, ID, MT
Canada: BC, southern Manitoba, and northwestern Ontario

Environmental Description:
This relatively widespread alliance occurs on pond and lake margins and in backwater areas. It also occupies basins where the water table may remain relatively high but can drop below the soil surface late in the growing season. Elevations range from sea level in coastal areas to 2,025 m in Montana. Stands of this alliance are flooded for most or all of the growing season. Stands can have water from 0 (exposed soil) to approximately 1.5 m deep but usually are less than 1 m.

Vegetation Description:
Vegetation is characterized by medium to tall graminoids that typically range from 1 to more than 2 m. The vegetation is moderately dense to dense. Some stands are heavily dominated by one or two *Scirpus (S. acutus* or *S. californicus),* while others have several graminoids common throughout the stand. In the United States, the most abundant species are typically *Scirpus acutus*, *S. fluviatilis*, and *S. tabernaemontani*. Species composition and abundance can vary from year to year depending mostly on water level fluctuations. In most years, typical species include *Lemna* spp., *Phragmites australis*, *Scirpus americanus* (in alkaline stands), *Triglochin maritimum* (in alkaline stands), *Typha latifolia*, and *Utricularia macrorhiza*. *Potamogeton* species often occur in the deeper parts of stands of this alliance, where emergent species are not densely packed. Shrubs, such as *Salix* spp., are not common but may become established in shallow water areas. During droughts, species more tolerant of low water, such as *Polygonum amphibium*, may invade and alter the species composition of stands of this alliance.

Comments:
Traditionally, *Scirpus californicus* has not been included as a diagnostic component of this alliance, but in many stands in California both *S. acutus* and *S. californica* co-occur or the two species appear to be ecologically interchangeable, especially in Suisun Marsh and southern California (Evens and San 2005, Keeler-Wolf and Vaghti 2000, Reid et al. 1999, Sawyer and Keeler-Wolf 1995, Weaver 1960).

Selaginella bigelovii/Eriogonum fasciculatum Association

Bushy Spike Moss/California Buckwheat Association
***Selaginella bigelovii* Herbaceous Alliance**
Bushy Spike Moss Herbaceous Alliance

Mapping Code: 4811

Local Description

Summary:
This herbaceous association occurs on moderately steep to very steep slopes of variable aspect at low to mid elevations between 81 and 862 m. It is dominated by *Selaginella bigelovii* in the low layer. *Eriogonum fasciculatum* is characteristically abundant in the shrub layer, and *Quercus agrifolia, Schinus molle,* and *Eucalyptus* spp. are infrequently found in the tree layer at low cover.

Distribution:

This association is sampled in the Upper Elevation Santa Monica Mountains, Western Fog Zone, Eastern Urban, Simi Hills Inland, Dry Inland, and Lower Elevation Inland Santa Monica Mountains regions of the study area.

Environmental Description:
Elevation: range 81–862 m, mean 464.4 m
Aspect: variable (southwest and northwest most common)
Slope: range 7–55 degrees, mean 29.5 degrees
Topography (micro; macro): variable, but usually undulating; variable
Litter Cover: range 1–20%, mean 7.6%
Small Rock Cover: range 0–75%, mean 22.3%
Large Rock Cover: range 8–95%, mean 44.5%
Bare Ground: range 1–65%, mean 14.3%
Parent Material: often igneous, infrequently sedimentary or depositional
Soil Texture: moderately fine clay loam or sandy clay loam

Vegetation Description:
Stands of the *Selaginella bigelovii/Eriogonum fasciculatum* Association form an open to intermittent cryptogam layer (2–48%, mean 15.5%) at 0.01–1 m tall. The shrub layer is open (1–28%, mean 10.9%) at 0–5 m tall. Trees are infrequently emergent (0–2% cover, mean 0.1%) with hardwoods at 0–10 m tall. Total vegetation cover is 4–49%, mean cover is 26.1%.

In this association, *Selaginella bigelovii* is characteristically abundant in the cryptogam layer where lichens and mosses are also sometimes found. The herbaceous layer is diverse and can include many native and nonnative species. *Eriogonum fasciculatum* is characteristically common in the shrub layer at low cover. Other shrubs such as *Yucca whipplei, Adenostoma fasciculatum, Artemisia californica, Malosma laurina, Mimulus aurantiacus,* and *Ceanothus crassifolius* are occasionally present at low cover. The tree layer infrequently includes *Quercus agrifolia, Schinus molle,* and *Eucalyptus* spp. as sparse emergent trees.

Other Noteworthy Species:
Calochortus catalinae was found in 1 of 30 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and the CNPS R-E-D Code is 1-2-3. Global rank is G3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Delphinium parryi was found in 1 of 30 surveys of this plant community, which may be the rare *D. parryi* subsp. *blochmaniae.* Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and the CNPS R-E-D Code is 3-2-3. Global rank is G4T2, and state rank is S2.2. Federal listing is Species of Concern, and state listing is none (CNPS 2005, SAMO 2004).

Eriogonum crocatum was found in 4 of 30 surveys of this plant community. Regionally, the park considers this species as Rare. CNPS ranks this species as List 1B, and the CNPS R-E-D Code is 2-2-3. Global rank is G2, and state rank is S2.1. Federal listing is Species of Concern, and state listing is Rare (CNPS 2005, SAMO 2004).

Leptodactylon californicum was found in 1 of 30 surveys of this plant community, which may be the rare species *L. C.* subsp. *tomentosum*. Regionally, the park considers this species as Rare. CNPS ranks this species as List 4, and CNPS R-E-D Code is 1-2-3. Global rank is G5T3, and state rank is S3.2. Federal listing is none, and state listing is none (CNPS 2005, SAMO 2004).

Nonnative Species:
Bromus madritensis, Bromus diandrus, Avena, Bromus hordeaceus, Avena fatua, Avena barbata, Brassica nigra, Erodium cicutarium, Senecio vulgaris, Silene gallica, Centaurea melitensis, Galium aparine, Lolium multiflorum, Schinus molle, Erodium, Carduus pycnocephalus, Eucalyptus, Hypochaeris, Lamarckia aurea, Salsola tragus

Samples Used in Description: (n = 30)
AA0031cc, AA0351cc, AA0434, AA0742cc, AA0747cc, AA0749cc, AA1212, rap0370m, rap0603, rap0605, rap0726, rap0792, rap0793, rap0794m, rap1495, rap1534, rap1618, rap1786, rap2088, rap2222, rap2224, rap2259, rap2287, rap2323, rap2584, rap2652, rap2759, rap2764, rap2765, rap2812

Comments:
This is a characteristic rock outcrop association of both volcanic and sedimentary outcrops in the study area. It typically occurs on relatively gently to moderately sloping slabs of rock and over time may form a thin to moderately thick mat of intertwined roots and rhizomes. These catch soil and dust and build up enough soil to supply substrate for other herbaceous species. The presence of a *Selaginella bigelovii* Alliance has not been identified so far in the national vegetation classification system. These herbaceous stands are visible on outcrops at a distance and often show up as dark mats with emergent drying grass stems and scattered shrubs.

Phases:
None

COMMON NAME	Bushy Spike Moss/California Buckwheat Herbaceous Association
SYNONYM	None
FORMATION CLASS	V. Herbaceous vegetation
FORMATION SUBCLASS	V.B. Perennial forb vegetation
FORMATION GROUP	V.B.2. Temperate or subpolar perennial forb vegetation
FORMATION SUBGROUP	V.B.2.N. Natural/Seminatural temperate or subpolar perennial forb vegetation
FORMATION NAME	V.B.2.N.b. Low temperate or subpolar perennial forb vegetation
ALLIANCE	*Selaginella bigelovii* Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G4S3

Global Description

Distribution:
It is likely that this association and *Selaginella bigelovii* Alliance will prove to be fairly widespread in southern California along expansive rocky substrates including on some of the offshore islands. For example, sampling in inland San Diego County represented one stand of this *Selaginella bigelovii/Eriogonum fasciculatum* Association on south-facing granitoid rocky slopes. Further anecdotal observation suggests that this association may occur in several places in coastal southern California such as the Santa Susana Mountains and the San Gabriel Mountains.

Nations:
United States

States or Provinces:
CA

Environmental Description:
This association is characteristically found on exposed rock outcrops that are usually somewhat steep to steep slopes of igneous or sedimentary parent material.

Vegetation Description:
Stands contain *Selaginella bigelovii* usually as dominant at more than 10% cover. Other cryptogams may be present such as moss and lichen. The herbaceous layer is diverse and can include many native and nonnative species including *Dudleya* spp., *Lessingia filaginifolia, Phacelia* spp., *Bromus madritensis,* and *Avena* spp. Low woody shrubs and subshrubs are present (usually well under 10% cover) but lower in cover than the average *Selaginella* cover. *Eriogonum fasciculatum* is characteristically common in the shrub layer at low cover. Other shrubs may include *Yucca whipplei, Artemisia californica,* and *Adenostoma fasciculatum.*

Comments:
Other *Selaginella* alliances (e.g., *S. Selaginella [tortipila, rupestris]* Alliance*; Sedum nuttallianum* Sparsely Vegetated Alliance) are known from the national vegetation classification (NatureServe 2005). However, the *S. bigelovii* Alliance is the first to be described from California (Evens and San 2005).

Typha sp. Herbaceous Alliance

Cattail Herbaceous Alliance

Mapping Code: 4420

Local Description

Summary:
One stand of this alliance occurs on relatively flat land at low elevation, in wetland habitats such as pond margins and coastal lagoons. It is dominated by *Typha* sp. in the herbaceous layer and has no shrubs or trees.

Distribution:
This association is sampled in the Immediate Coast region of the study area.

Environmental Description:
Elevation: no data
Aspect: flat
Slope: 2 degrees
Topography (micro; macro): flat; bottom
Litter Cover 80%
Small Rock Cover: no data
Large Rock Cover: no data
Bare Ground: no data
Parent Material: depositional
Soil Texture: sand (class unknown)

Vegetation Description:
One stand of this herbaceous alliance forms an intermittent herbaceous layer (60%) at 0.5–1 m tall. Total vegetation cover is 60%.

In this stand, the herbaceous layer is intermittent and dominated by *Typha*. *Scirpus californicus*, *Cakile maritime,* and *Distichlis spicata* are also included in this layer at relatively low cover.

***Typha* sp. Alliance**

Layer	Code	Species Name	Con	Avg	Min	Max	A	C	N
Herb									
	TYPHA	*Typha*	100	55.0	55.0	55.0	X	X	
	SCCA	*Scirpus californicus*	100	3.0	3.0	3.0		X

	DISP	*Distichlis spicata*	100	0.2	0.2	0.2		X	
	RUCR	*Rumex crispus*	100	0.2	0.2	0.2		X	X

Other Noteworthy Species:
None

Nonnative Species:
Cakile maritima, Cortaderia, Rumex crispus

Samples Used in Description: (n = 1)
rap2615

Comments:
Typha stands are uncommon in small and local stands within the study area. They may occur in ponds, slow moving stretches of creeks, or along borders of coastal lagoons.

Phases:
None

COMMON NAME	Cattail Alliance
SYNONYM	None
PHYSIOGNOMIC CLASS	V. Herbaceous vegetation
PHYSIOGNOMIC SUBCLASS	V.A. Perennial graminoid vegetation
PHYSIOGNOMIC GROUP	V.A.5. Temperate or subpolar grassland
PHYSIOGNOMIC SUBGROUP	V.A.5.N. Natural/Seminatural
FORMATION	V.A.5.N.I. Semipermanently flooded temperate or subpolar grassland
ALLIANCE	*Typha* sp. Herbaceous Alliance
CLASSIFICATION CONFIDENCE LEVEL	1
ECOLOGICAL REGIONS	261Bf Santa Monica Mountains, 261Be Simi Valley-Santa Susana Mountains
CONSERVATION STATUS RANK	G5S5

Global Description

Distribution:
This alliance is found at low to moderate elevations in virtually every state in the United States and probably most Canadian provinces.

Nations:
United States, Canada, Mexico

States or Provinces:
virtually all states and provinces in North America

Environmental Description:
This alliance is found most commonly along lake or pond margins, by slow-moving ditches, in shallow basins, adjacent to stream or river channels, in wet mud, in oxbows, and occasionally in river backwaters. Elevations range from near sea level to around 2,000 m in Colorado. Sites where this alliance occur are typically semipermanently flooded, inundated with 30 to 100 cm of water throughout the year. Lacustrine cattail marshes typically have a muck-bottom zone bordering the shoreline, where cattails are rooted in the bottom substrate and a floating mat zone where the roots grow suspended in a buoyant peaty mat. *Typha angustifolia* can grow in deeper water compared to *Typha latifolia*, although both species reach maximum growth at a water depth of 50 cm.

Vegetation Description:
Vegetation is characterized by *Typha* as the main dominant species including *T. angustifolia, T. latifolia,* and/or *T. domingensis* (Hansen et al. 1995, Reid et al. 1999, Sawyer and Keeler-Wolf

1995). Other wetland graminoids or forb species may be present at low cover including *Cyperus* sp., *Scirpus californicus,* and *Rumex* sp. *Typha* species are prolific seed producers, spreading rapidly to become the early colonizers of wet mineral soil, and will persist under wet conditions. Roots and lower stems are well adapted to prolonged submergence, but periods of drawdown are required for seed germination to occur.

Comments:
None

Appendix E

VEGETATION SAMPLING PROTOCOLS AND FIELD FORMS

APPENDIX 1. Vegetation Sampling Protocols and Field Forms

CALIFORNIA NATIVE PLANT SOCIETY –
VEGETATION RAPID ASSESSMENT PROTOCOL
CNPS VEGETATION COMMITTEE
(November 5, 2001, Revised SAMO July 23, 2002)

Introduction

The rapid assessment protocol is a reconnaissance-level method of vegetation and habitat sampling. It may be used to quickly assess and map the extent of all vegetation types in relatively large, ecologically defined regions. The California Native Plant Society (CNPS) has adopted this method to verify locations of known vegetation types, to gain information about new types, and to acquire general information about their composition, habitat, and site quality. Other agencies, such as California State Parks and the U.S. Forest Service, are also adopting this method for documenting vegetation patterns.

By using this method, biologists and resource managers can gain a broad ecological perspective, as the full range in ecological variation across broad landscapes can be reflected in the vegetation assessments. For example, changes in environmental elements (such as geology, aspect, topographic position) or physical processes (fire, flooding, erosion, and other natural or human-made disturbances) can influence the distribution of plants or patterning of vegetation, which are documented in the rapid assessments. In turn, these vegetation patterns can influence the distribution of animals across the landscape.

The quantitative vegetation data recorded in the rapid assessments can be described with standard classification techniques and descriptions, and they can be depicted in maps across any landscape. Additional information recorded in the assessments, such as disturbance history and anthropogenic impacts, can serve to define habitat quality and integrity for plant and animal distributions. Because this method provides an important means for representing the full array of biological diversity as well as habitat integrity in an area, it can also be an effective and efficient tool for conducting natural resource planning.

Purpose

The Vegetation Program has adopted the rapid assessment method to update the location, distribution, species composition, and disturbance information of vegetation types as identified in the first edition of *A Manual of California Vegetation* (MCV), a CNPS publication. The release of the MCV heralded a new statewide perspective on vegetation classification. The premise of the book – all vegetation can be quantified based on cover, constancy, and composition of plant species, yielding uniform defensible definitions of vegetation units – has proven to be very useful throughout California and the rest of the nation. The MCV has become the standard reference on California vegetation and has been adopted by many agencies such as

California Department of Fish and Game, the National Park Service, and the U.S. Forest Service as the standard approach to classify vegetation statewide.

One of the most important purposes of rapid assessments is to verify the locations of each vegetation type because much about the geography of vegetation remains uncertain in this state. To obtain a more accurate understanding of the location and distribution of the vegetation types, nothing short of systematic inventory will suffice. Using the rapid assessment method, CNPS Chapters and other organizations can work together in selected ecological regions to gather vegetation data over a short time period in a broad area. This geographic inventory of vegetation types can greatly advance the current distribution understanding of vegetation.

In addition, California is working with a new vegetation classification, and its parameters are largely untested. The rapid assessment method will be used to gather additional information on species composition, distribution, disturbance effects, and environmental influences of vegetation. Thus, this method will provide modifications to the existing vegetation classifications and information on new types.

This protocol can also be used in tandem with other resource assessment protocols such as California Wildlife Habitat Relationships (CWHR) protocols to obtain detailed records on habitat quality and suitability for vertebrate animals in any terrestrial habitat. The CWHR protocols can also help test the relationships between the vegetation type and habitat of various animals and thereby refine the understanding and predictability of the distribution of animals. A portion of the CWHR protocols is incorporated into the rapid assessment method to obtain suitability information for vertebrate species.

While people can quickly obtain information on the variety of vegetation types using this method, some of the vegetation types recorded in the rapid assessment process may be poorly defined in the current classification system. These poorly understood or unknown types will be identified and located and then will be prioritized for more detailed assessment using the CNPS relevé protocol. Thus, the rapid assessment method will be used in conjunction with the relevé method to provide large quantities of valuable data on the distribution and the definition of vegetation. These data will be entered into existing databases for summarizing and archiving, and they will be used to modify and improve statewide vegetation classification and conservation information.

<u>Why do we need to know about the composition and distribution of vegetation?</u>

- to have a more accurate understanding of the commonness and rarity of different forms of vegetation throughout the state
- to link the distribution of various rare and threatened plant species with the vegetation units
- to provide a clearer picture of relationships between vegetation types
- to help prioritize community-based land conservation goals based on the local representation of unique types, high diversity areas, etc.

- to do the same for regional vegetation throughout the state and the nation.
- to broaden the vegetation knowledge base for California
- to motivate people to do more to help identify, protect, and conserve vegetation in their area
- to link vegetation types with habitat for animals

Selecting stands to sample:

To start the rapid assessment method, stands of vegetation needs to be defined.
A stand is the basic physical unit of vegetation in a landscape. It has no set size. Some vegetation stands are very small, such as alpine meadow or tundra types, and some may be several square kilometers in size, such as desert or forest types. A stand is defined by two main unifying characteristics:

1) It has compositional integrity. Throughout the site, the combination of species is similar. The stand is differentiated from adjacent stands by a discernable boundary that may be abrupt or indistinct.
2) It has structural integrity. It has a similar history or environmental setting that affords relatively similar horizontal and vertical spacing of plant species. For example, a hillside forest originally dominated by the same species that burned on the upper part of the slopes, but not the lower, would be divided into two stands. Likewise, a sparse woodland occupying a slope with very shallow rocky soils would be considered a different stand from an adjacent slope with deeper, moister soil and a denser woodland or forest of the same species.

The structural and compositional features of a stand are often combined into a term called homogeneity. For an area of vegetated ground to meet the requirements of a stand, it must be homogeneous.

Stands to be sampled may be selected by evaluation prior to a site visit (*e.g.* delineated from aerial photos or satellite images), or they may be selected on site (during reconnaissance to determine extent and boundaries, location of other similar stands, etc.).

Depending on the project goals, you may want to select just one or a few representative stands of each homogeneous vegetation type for sampling (*e.g.* for developing a classification for a vegetation mapping project), or you may want to sample all of them (*e.g.* to define a rare vegetation type and/or compare site quality between the few remaining stands).

Definitions of fields in the protocol

LOCATIONAL/ENVIRONMENTAL DESCRIPTION

Polygon/Stand #: Number assigned either in the field or in the office prior to sampling. It is usually denoted with an abbreviation of the sampling location and then a sequential number of that locale (*e.g.* CRRA-001 for Coyote Ridge rapid assessment number 1).

Air photo #: The number given to the aerial photo in a vegetation-mapping project, for which photointerpreters have already done photointerpretation and delineations of polygons. If the sample site has not been photo-interpreted, leave blank.

Date: Date of the sampling.

Name(s) of surveyors: The full names of each person assisting should be provided for the first rapid assessment. In successive assessments, initials of each person assisting can be recorded. Please note: The person recording the data on the form should circle their name/initials.

GPS waypoint #: The waypoint number assigned by a Global Positioning System (GPS) unit when marking and storing a waypoint for the stand location. These waypoints can be downloaded from the GPS into a computer Geographic Information System to depict sample points accurately on a map.

GPS name: The name personally assigned to each GPS unit (especially useful if more than one GPS unit is used to mark waypoints for the project).

GPS datum: (NAD 27) The map datum that is chosen for GPS unit to document location coordinates. The default datum for CNPS projects is NAD 27. However, other agencies and organizations may prefer another datum. Please circle NAD27 or write in the appropriate datum.

Is GPS within stand? Yes / No Circle "Yes" to denote that the GPS waypoint was taken directly within or at the edge of the stand being assessed, or circle "No" to denoted the waypoint was taken at a distance from the stand (such as with a binocular view of the stand).

If No cite distance (note ft/m), bearing and view from point to stand: An estimate of the number of feet or meters (please circle appropriate), the compass bearing from the waypoint of GPS to the stand, and the method of view used to verify the plot (*e.g.* binoculars, aerial photo).

Error: ± The accuracy of the GPS location, when taking the UTM field reading. Please denote feet (ft) or meters (m). It is typical for all commercial GPS units to be accurate to within 5 m (or 16 ft.) of the actual location, because the military's intentional imprecision (known as "selective availability") has been "turned off" as of July 2000. Please become familiar with your GPS unit's method of determining error. Some of the lower cost models do not have this ability. If using one of those, insert N/A in this field.

UTM field reading: Easting (UTME) and northing (UTMN) location coordinates using the Universal Transverse Mercator (UTM) grid. Record using a GPS unit or USGS topographic map.

UTM zone: Universal Transverse Mercator zone. Zone 10S for California west of the 120th longitude; zone 11S for California east of 120th longitude.

Elevation: Recorded from the GPS unit or USGS topographic map. Please denote feet (ft) or meters (m), and note if reading is from GPS unit or map. (Please note: Readings taken from a GPS unit can be hundreds of feet off.)

Photograph #'s: Note the roll number, frame number, direction, and the name of the person whose camera is being used. Take at least two photographs from different directions, and describe the location and view direction from compass bearings for each frame. Additional photographs of the stand may also be helpful. (Also, if using a digital camera or scanning the image into a computer, positions relative to the polygon/stand number can be recorded digitally.)

Topography: Check two of the provided features, characterizing both the local relief and the broad topographic position of the area. First assess the minor topographic features or the lay of the area (*e.g.* surface is flat, concave, etc.). Then assess the broad topographic feature or general position of the area (*e.g.* stand is at the bottom, lower (1/3 of slope), middle (1/3 of slope), upper (1/3 of slope), or top).

Geology: Geological parent material of site. If exact type is unknown, use a more general category (*e.g.* igneous, metamorphic, sedimentary). *See code list for types.*

Soil: Record soil texture or series that is characteristic of the site (*e.g.* sand, silt, clay, coarse loamy sand, sandy clay loam, saline, et.). *See soil texture key and code list for types.*

% Large Rock (optional): Estimate the percent surface cover of large rocks (e.g. stones, boulders, bedrock) that are beyond 25 cm in size.

% Small Rock (optional): Estimate the percent surface cover of small rocks (e.g. gravel, cobbles) that are greater than 2 mm and less than 25 cm in size.

% Bare/Fines (optional): Estimate the percent surface cover of bare ground and fine sediment (e.g. dirt) that is 2 mm or less in size.

General slope exposure (circle one and enter actual º): Read degree aspect from a compass or clinometer (or estimate). Make sure to average the reading across entire stand. "Variable" may be selected if the same, homogenous stand of vegetation occurs across a varied range of slope exposures.

General slope steepness (circle one and enter actual º): Read degree slope from compass (or estimate), using degrees from true north (adjusting for declination). Average the reading over entire stand.

Upland or Wetland (circle one) Indicate if the stand is in an upland or a wetland; note that a site need not be officially delineated as a wetland to qualify as such in this context (*e.g.* seasonally wet meadow).

Site history, stand age, and comments: Briefly describe the stand age/seral stage, disturbance history, nature and extent of land use, and other site environmental and vegetation factors. Examples of disturbance history: fire, landslides, avalanching, drought, flood, animal burrowing, or pest outbreak. Also, try to estimate year or frequency of disturbance. Examples of land use: grazing, timber harvest, or mining. Examples of other site factors: exposed rocks, soil with fine-textured sediments, high litter/duff build-up, multi-storied vegetation structure, or other stand dynamics.

Type / level of disturbance (use codes): List codes for potential or existing impacts on the stability of the plant community. Characterize each impact each as L (=Light), M (=Moderate), or H (=Heavy). *See code list for impacts.*

VEGETATION DESCRIPTION

Basic alliance and stand description.

Field-assessed vegetation alliance name: Name of alliance (series) or habitat following the CNPS classification system (Sawyer and Keeler-Wolf 1995). Please use binomial nomenclature, *e.g. Quercus agrifolia* forest. An alliance is based on the dominant (or diagnostic) species of the stand, and is usually of the uppermost and/or dominant height stratum. A dominant species covers the greatest area (and a diagnostic is consistently found in some vegetation types but not others).

Please note: The field-assessed alliance name may not exist in present classification, in which you can provide a new alliance name in this field. If this is the case, also make sure to denote and explain this in the "Cannot identify alliance based on MCV classification" of the "**Problems with Interpretation**" section below.

Field-assessed association name (optional): Name of the species in the alliance and additional dominant/diagnostic species from any strata, as according to CNPS classification. In following naming conventions, species in differing strata are separated with a slash, and species in the uppermost stratum are listed first (*e.g. Quercus agrifolia/Toxicodendron diversilobum*). Species in the same stratum are separated with a dash (*e.g. Quercus agrifolia-Quercus kelloggii).*

Please note: The field-assessed association name may not exist in present classification, in which you can provide a new association name in this field.

Size of stand: Estimate the size of the entire stand in which the rapid assessment is taken. As a measure, one acre is about 0.4 hectares or about 4000 square meters.

Number of encounters of this alliance (tally/circle once): This estimate can be done for a landscape-level project of a general area, ecological subsection, watershed, etc., though it is not required. Make an estimate of the total number of times that this alliance was seen in the project survey and recorded on field forms.

Please note: This estimation should only be done once, at the end of a project survey, for every alliance identified in the field. Please provide the tally once for each alliance, and provide the estimate on the first rapid assessment field form that was filled out for each alliance.

Habitat classification per California Wildlife-Habitat Relationships (CWHR)
For CWHR, identify the size/height class of the stand using the following tree, shrub, and/or herbaceous categories. These categories are based on functional life forms.

Tree: Circle one of the tree size classes provided when the tree canopy closure exceeds 10 percent of the total cover (except in desert types), or if young tree density indicates imminent tree dominance. Size class is based on the average dbh (diameter of trunk at breast height). In choosing a size class, make sure to estimate the mean diameter of all trees over the entire stand. Circle the size class 6 multi-layered tree if there is a size class 5 of trees over a distinct layer of size class either 3 or 4 (*i.e.*, distinct height class separation between different tree species) and the total tree canopy exceeds 60%.

If tree, list 1-3 dominant overstory species: If tree canopy cover exceeds 10 percent (except in desert types), please list the dominant species that occur in the overstory canopy.

Shrub: Circle one of the shrub size classes provided when shrub canopy closure exceeds 10 percent (except in desert types). Size class is based on the average amount of crown decadence (dead standing vegetation on live shrubs when looking across the crowns of the shrubs).

Herbaceous: Circle one of the herb height classes provided when herbaceous cover exceeds 2 percent. This height class is based on the average plant height at maturity.

Desert Palm/Joshua Tree: Circle one of the palm or Joshua tree size classes by averaging all the stem-base diameters (*i.e.*, mean diameter of all stem-base sizes). Diameter is measured at the plant's base above the bulge near the ground.

Desert Riparian Tree/Shrub: Circle one of the size classes by measuring mean stem height (whether tree and/or shrub stand).

Overall cover of vegetation
Provide an ocular estimate of cover for the following categories (based on functional life forms). Record a specific number for the total aerial cover or "bird's-eye view" looking from above for each category, estimating cover for the living plants only. Litter/duff should not be included in these estimates.

To come up with a specific number estimate for percent cover, first use to the following CWHR cover intervals as a reference aid to get a generalized cover estimate: <2%, 2-9%, 10-24%, 25-39%, 40-59%, 60-100%. While keeping these intervals in mind, you can then refine your estimate to a specific percentage for each category below.

%Overstory Conifer/Hardwood Tree cover: The total aerial cover (canopy closure) of all live tree species that are specifically in the overstory or are emerging, disregarding overlap of individual trees. Estimate conifer and hardwood covers separately. Please note: These cover values should not include the coverage of suppressed understory trees.

Shrub cover: The total aerial cover (canopy closure) of all live shrub species, disregarding overlap of individual shrubs.

Ground cover: The total aerial cover (canopy closure) of all herbaceous species, disregarding overlap of individual herbs.

Total Veg cover: The total aerial cover of all vegetation. This is an estimate of the absolute vegetation cover, disregarding overlap of the various tree, shrub, and/or herbaceous layers.

Modal height for conifer/hardwood tree, shrub, and herbaceous categories *(optional)*
If height values are important in your vegetation survey project, provide an ocular estimate of height for each category listed. Record an average height value, estimating the modal height for each group. Use the following height intervals and record a height class: 01=<1/2m, 02=1/2-1m, 03=1-2m, 04=2-5m, 05=5-10m, 06=10-15m, 07=15-20m, 08=20-35m, 09=35-50m, 10=>50m.

SPECIES LIST AND COVERAGE

Species (List up to 12 major species), Stratum, and Approximate % cover: (Jepson Manual nomenclature please)

List the species that are dominant or that are characteristically consistent throughout the stand.

When different layers of vegetation occur in the stand, make sure to list species from each stratum. As a general guide, make sure to list at least 1-2 of the most abundant species per

stratum. Provide a stratum code for each species listed, based on height, where T (=Tall) is >5 m in height, M (=Medium) is between 0.5 and 5 m in height, and L (=Low) is <0.5 m in height.

Also, provide a numerical ocular estimate of aerial coverage for each species. When estimating, it is often helpful to think of coverage in terms of the cover intervals from the CNPS relevé form at first (*e.g.* <1%, 1-5%, >5-15%, >15-25%, >25-50%, >50-75%, >75%). Keeping these classes in mind, then refine your estimate to a specific percentage (*e.g* the cover of species "x" is somewhere between 25 and 50 percent, but I think it is actually around 30%). Please note: All estimates are to be reported as absolute cover (not relative cover), and all the species percent covers may total over 100% when added up because of overlap.

Major nonnative species in stand (with % cover): All exotic species occurring in the stand should be listed in this space provided (or they can be recorded in the above Species list). Make sure to give each exotic species an absolute coverage estimate.

Unusual species: List species that are either locally or regionally rare, endangered, or atypical (*e.g.* range extension or range limit) within the stand. This species list will be useful to the Program for obtaining data on regionally or locally significant populations of plants.

PROBLEMS WITH INTERPRETATION

Confidence in Identification: (L, M, H) With respect to the "field-assessed alliance name", note whether you have L (=Low), M (=Moderate), or H (=High) confidence in the interpretation of this alliance name. Low confidence can occur from such things as a poor view of the stand, an unusual mix of species that does not meet the criteria of any described alliance, or a low confidence in your ability to identify species that are significant members of the stand.

Cannot identify alliance based on MCV classification? (Check if appropriate) and Explain: If the field-assessed alliance name is not defined by CNPS's present Manual of California Vegetation (MCV) classification, note this in the space and describe why. In some instances for specific projects, there may be the benefit of more detailed classifications than what is presented in the first edition of the MCV. If this is the case, be sure to substitute the most appropriate and detailed classification.

Other identification problems (describe): Discuss any further problems with the identification of the assessment (*e.g.* stand is observed with an oblique view using binoculars, so the species list may be incomplete, or the cover percentages may be imperfect).

Polygon is more than one type (Yes, No) (Note: type with greatest coverage in polygon should be entered in above section) This is relevant to areas that have been delineated as polygons on aerial photographs for a vegetation-mapping project. In most cases the polygon delineated is intended to represent a single stand, however mapping conventions and the constraints and interpretability of remote images will alter the ability to map actual stands on the

ground. "Yes" is noted when the polygon delineated contains the field-assessed alliance and other vegetation type(s), as based on species composition and structure. "No" is noted when the polygon is primarily representative of the field-assessed alliance.

Other types: If "Yes" above, then list the other subordinate vegetation alliances that are included within the polygon. List them in order of their amount of the polygon covered.

Has the vegetation changed since air photo taken? (Yes, No) If an aerial photograph is being used for reference, evaluate if the stand of the field-assessed alliance has changed as a result of disturbance or other historic change since the photograph was taken.

If Yes, how? What has changed (write N/A if so)**?** If the photographic signature of the vegetation has changed (*e.g.* in structure, density, or extent), please detail here.

Simplified Key to Soil Texture (Brewer and McCann, 1982)

Place about three teaspoons of soil in the palm of your hand. Take out any particles >2mm in size, and use the following key to figure out the soil texture (e.g. loamy sand). Then figure out the texture subclass by using the Code List attached (e.g. coarse loamy sand).

A1 Soil does not remain in a ball when squeezed.....sand

A2 Soil remains in a ball when squeezed..... B

B1 Add a small amount of water. Squeeze the ball between your thumb and forefinger, attempting to make a ribbon that you push up over your finger. Soil makes no ribbon.....loamy sand

B2 Soil makes a ribbon; may be very short.....C

C1 Ribbon extends less than 1 inch before breaking.....D

C2 Ribbon extends 1 inch or more before breaking.....E

D1 Add excess water to small amount of soil; soil feels very gritty or at least slightly gritty .....loam or sandy loam

D2 Soil feels smooth.....silt loam

E1 Soil makes a ribbon that breaks when 1–2 inches long; cracks if bent into a ring.....F

E2 Soil makes a ribbon 2+ inches long; does not crack when bent into a ring.....G

F1 Add excess water to small amount of soil; soil feels very gritty or at least slightly gritty.....sandy clay loam or clay loam

F2 Soil feels smooth.....silty clay loam or silt

G1 Add excess water to a small amount of soil; soil feels gritty or at least slightly gritty.....sandy clay or clay

G2 Soil feels smooth.....silty clay

CALIFORNIA NATIVE PLANT SOCIETY RELEVÉ FIELD FORM CODE LIST

(revised 7/8/02)

MACRO TOPOGRAPHY

00 Bench
01 Ridge top (interfluve)
02 Upper 1/3 of slope
03 Middle 1/3 of slope
04 Lower 1/3 of slope (lowslope)
05 Toeslope (alluvial fan/bajada)
06 Bottom/plain
07 Basin/wetland
08 Draw
09 Other
10 Terrace (former shoreline or floodplain)
11 Entire slope

PARENT MATERIAL

ANDE	Andesite
ASHT	Ash (of any origin)
GRAN	Granitic (generic)
GREE	Greenstone
DIOR	Diorite
BASA	Basalt
OBSI	Obsidian
PUMI	Pumice
IGTU	Igneous (type unknown)
MONZ	Monzonite
PYFL	Pyroclastic flow
QUDI	Quartz diorite
RHYO	Rhyolite
VOLC	General volcanic extrusives
VOFL	Volcanic flow
VOMU	Volcanic mud
BLUE	Blue schist
CHER	Chert
DOLO	Dolomite
FRME	Franciscan melange
INTR	General igneous intrusives
GNBG	Gneiss/biotite gneiss
HORN	Hornfels
MARB	Marble
METU	Metamorphic (type unknown)
PHYL	Phyllite
SCHI	Schist
SESC	Semi-schist
SLAT	Slate
BREC	Breccia (non-volcanic)
CACO	Calcareous conglomerate
CASA	Calcareous sandstone
CASH	Calcareous shale
CASI	Calcareous siltstone
CONG	Conglomerate
FANG	Fanglomerate
GLTI	Glacial till, mixed origin, moraine
LALA	Large landslide (unconsolidated)
LIME	Limestone
SAND	Sandstone
SETU	Sedimentary (type unknown)
SHAL	Shale
SILT	Siltstone
DIAB	Diabase
GABB	Gabbro
PERI	Peridotite
SERP	Serpentine
ULTU	Ultramafic (type unknown)
CALU	Calcareous (origin unknown)
DUNE	Sand dunes
LOSS	Loess
MIIG	Mixed igneous
MIME	Mixed metamorphic
MIRT	Mix of two or more rock types
MISE	Mixed sedimentary
CLAL	Clayey alluvium
GRAL	Gravelly alluvium
MIAL	Mixed alluvium
SAAL	Sandy alluvium (most alluvial fans and washes)
SIAL	Silty alluvium
OTHE	Other than on list

SOIL TEXTURE

COSA	Coarse sand
MESN	Medium sand
FISN	Fine sand
COLS	Coarse, loamy sand
MELS	Medium to very fine, loamy sand
MCSL	Moderately coarse, sandy loam
MESA	Medium to very fine, sandy loam
MELO	Medium loam
MESIL	Medium silt loam
MESI	Medium silt
MFCL	Moderately fine clay loam
MFSA	Moderately fine sandy clay loam
MFSL	Moderately fine silty clay loam
FISA	Fine sandy clay
FISC	Fine silty clay
FICL	Fine clay
SAND	Sand (class unknown)
LOAM	Loam (class unknown)
CLAY	Clay (class unknown)
UNKN	Unknown

DOMINANT VEGETATION GROUP

Trees:

TBSE	Temperate broad-leaved seasonal evergreen forest
TNLE	Temperate or subpolar needle-leafed evergreen forest
CDF	Cold-deciduous forest
MNDF	Mixed needle-leafed evergreen-cold-deciduous. forest
TBEW	Temperate broad-leaved evergreen woodland
TNEW	Temperate or subpolar needle-leaved evergreen woodland
EXEW	Extremely xeromorphic evergreen woodland
CDW	Cold-deciduous woodland
EXDW	Extremely xeromorphic deciduous woodland
MBED	Mixed broad-leaved evergreen-cold-deciduous woodland
MNDW	Mixed needle-leafed evergreen-cold-deciduous woodland

Shrubs:

TBES	Temperate broad-leaved evergreen shrubland
NLES	Needle-leafed evergreen shrubland
MIES	Microphyllus evergreen shrubland
EXDS	Extremely xeromorphic deciduous shrubland
CDS	Cold-deciduous shrubland
MEDS	Mixed evergreen-deciduous shrubland
XMED	Extremely xeromorphic mixed evergreen-deciduous shrubland

Dwarf Shrubland:

NMED	Needle-leafed or microphyllous evergreen dwarf shrubland
XEDS	Extremely xeromorphic evergreen dwarf shrubland
DDDS	Drought-deciduous dwarf shrubland
MEDD	Mixed evergreen cold-deciduous dwarf shrubland

Herbaceous:

TSPG	Temperate or subpolar grassland
TGST	Temperate or subpolar grassland with sparse tree
TGSS	Temperate or subpolar grassland with sparse shrublayer
TGSD	Temperate or subpolar grassland with sparse dwarf shrub layer
TFV	Temperate or subpolar forb vegetation

THRV	Temperate or subpolar hydromorphic rooted vegetation
TAGF	Temperate or subpolar annual grassland or forb vegetation

***Sparse Vegetation*:**

SVSD	Sparsely vegetated sand dunes
SVCS	Sparsely vegetated consolidated substrates

Releve Protocol
Santa Monica Mtns NRA

June 11, 2003

This document is intended to provide general instructions and guidelines for conducting Releves at SAMO NRA. Parts have been adapted from the Yosemite Releve Protocol or CNPS Rapid Assessment Protocol. For SAMO NRA, the Releve has essentially become an in-depth Rapid Assessment. That is to say essentially the same information is gathered for a Rapid Assessment as for a Releve with the addition of a complete species list. The other main difference between the two protocols is that for Releves, the species list is compiled from within a defined area as opposed to the entire stand.

The same field form is used for both RA and Releve information. However, not all fields are required for both data types.

Establishing a Plot

1) Figure out where to place your plot. This is a subjective process. You'll want to place your plots in areas that seem to be both relatively **homogenous** and **representative** of the vegetation of the polygon as a whole. In other words, avoid areas where the vegetation appears to be transitioning from one type to another, and areas with anomalous or heterogeneous structure or species composition. Take some time to do this carefully, because the plots you set up may become *permanent*; relocated and resampled over time in order to determine responses to management, and other useful things. Look at *all* the vegetation strata to determine if the area is structurally and floristically uniform and generally try to place your plots a fair distance from what you see as the 'boundary' between this vegetation type and any neighboring, distinctly different types. However, the rule-of-thumb is to conduct a reconnaissance of the plot if time and topography allows.

Note: In cases where a polygon is very heterogeneous, more than one plot may be needed. Again, look around, use that human perception.

2) Take GPS information from CENTER of plot. Remember that this may become a permanent plot, so being able to *find* it again will be key: use the GPS, rather than estimating! (If you cannot get a GPS reading, estimate the coordinates from the topo map and note on the form that you had to resort to this method.)

Note: You can deviate from the standard plot *shapes* where that makes sense, but the total plot *area* encompassed by the boundaries should be as listed above for each major class of vegetation. For example, forested riparian vegetation, may be sampled in a more linear, 10 x 100 m (1000 m^2) plot; herbaceous riparian or ridgeline vegetation in a 2 x 50 m (100 m^2) plot.

Standard plot sizes

If you're in a ...	You should make your plot...	Giving you a plot area of...
Forest (trees have their crowns overlapping, usually forming 60-100% cover)	20 m x 50 m	1000 m^2
Woodland (open stands of trees with crowns usually not touching. Canopy tree cover is 25-60% Or exceeds shrub, dwarf-shrub, herb, and nonvascular cover).	20 m x 50 m	1000 m^2
Shrubland (shrubs greater than 0.5 m tall are dominant, usually forming more than 25% cover OR exceeding tree, dwarf-shrub, herb, and nonvascular cover)	20 m x 20 m	400 m^2
Dwarf-shrubland (shrubs less than 0.5 m tall are dominant, usually forming more than 25% cover OR exceeding tree, shrub, herb, and nonvascular cover).	20 m x 20 m	400 m^2
Herbaceous (herbs dominant, usually forming more than 25% cover OR exceeding tree, shrub, dwarf-shrub, and nonvascular cover).	10 m x 10 m	100 m^2
Nonvascular (nonvascular cover dominant, usually forming more than 25% cover).	5 m x 5 m	25 m^2

Notes on Compiling Species list:

As you begin to collect the species, DBH, and cover information on page two, keep these four rules in mind—they will speed your data collection considerably:

1) If there are more than 25 trees over 10 cm DBH, measure a representative quarter of the plot (this may be any portion of the plot but should be 25% of the total plot area. CLEARLY NOTE on the form where this sub-sample was taken. Also, remember that DBH is an inherently inexact measurement (your 'breast height may be very different from the next ecologist's for one thing), so don't fret over this one—this should be a quick measurement!

2) Except in very diverse plots, don't spend more than **20 minutes** looking for new and different species to record. Remember that these plot data are to be used to classify the overall vegetation of the Park, not to make a complete species list for it. And if you had to spend much more than 20 minutes to *find* a species, it probably isn't going to be important in characterizing the vegetation type. For diverse plots with over 25 taxa you may take up to 30 minutes on the listing process.

3) We have asked you to estimate in cover classes, but often it is helpful to make and attempt to estimate an actual percent cover for certain species. This may be useful in getting a sense of total vegetation cover (by adding percentages) and in determining to which category a species that is a

borderline between two cover classes should be assigned. Try not to agonize over the percent cover column. This is only a rough visual estimate.

4) If you can't identify a plant to species, record the species on your form as "unknown species 1," "unknown species 2," "Carex unknown sp. 1," etC. Record cover class and other data for the unknown as you would for any other species.

If you need the species identified right away because it appears to be dominant or diagnostic (you're seeing it all over the place or you're seeing much more in this particular vegetation type than in others), take a sample of the species with as much of the plant as possible, especially intact sexual parts, if present. Place the sample in a baggie, and label the baggie with the plot code and the name you gave it on the data form. On an office day, take the time to key the plant out. If unable to get a definite ID, bag the plant and give it to the Inventory and Monitoring Botanist or send it to the UCLA herbarium curator.

Definitions of fields in the protocol

LOCATIONAL/ENVIRONMENTAL DESCRIPTION

Polygon/Stand #: Number assigned either in the field or in the office prior to sampling. If it is a polygon that AIS has requested information on, assign it the AIS number given on the In-house Field Map. If AIS has not requested information on the polygon (no AIS number to be assigned), use the next sequential number from your team's list of Releve numbers. Also be sure to label the location on paper copy of the photo overlay.

Air photo #: The number given to the aerial photo in a vegetation-mapping project, for which photointerpreters have already done photointerpretation and delineations of polygons. If the sample site has not been photo-interpreted, leave blank.

Date: Date of the sampling.

Name(s) of surveyors: The full names of each person assisting should be provided for their first rapid assessment. In successive assessments, initials of each person assisting can be recorded. Please note: The person recording the data on the form should circle their name/initials.

Initial AIS Code: 4-digit mapping classification code assigned by AIS at time of initial interpretation.

Field Crew Code: 4-digit code mapping classification code assigned by Field crew upon completion of form. This should correspond as closely as possible to the Field Alliance and Association Name (see below).

GPS waypoint #: The waypoint number assigned by a Global Positioning System (GPS) unit when marking and storing a waypoint for the stand location. These waypoints can be downloaded from the GPS into a computer Geographic Information System to depict sample points accurately on a map.

GPS name: The name personally assigned to each GPS unit (especially useful if more than one GPS unit is used to mark waypoints for the project).

GPS datum: (NAD 27) The map datum that is chosen for GPS unit to document location coordinates. The default datum for CNPS projects as well as SAMO projects is NAD 27. Please circle NAD27 or write in the appropriate datum.

Is GPS within stand? Yes / No Circle"Yes" to denote that the GPS waypoint was taken directly within or at the edge of the stand being assessed, or circle "No" to denoted the waypoint was taken at a distance from the stand (such as with a binocular view of the stand). For Releves, there is an additional field "If RELEVE, center of plot?". Be sure to describe location of the point if not taken at center.

If No cite distance (note ft/m), bearing and view from point to stand: An estimate of the number of feet or meters (please circle appropriate), the compass bearing from the waypoint of GPS to the stand, and the method of view used to verify the plot (*e.g.* binoculars, aerial photo).

If Releve, Center of plot? Yes/No If the plot being gathered is a releve, was the GPS point taken at the center of the releve? If it is not in the center, describe the location in the notes section.

Error: ± The accuracy of the GPS location, when taking the UTM field reading. Please denote feet (ft) or meters (m). It is typical for all commercial GPS units to be accurate to within 5 m (or 16 ft.) of the actual location, because the military's intentional imprecision (known as "selective availability") has been "turned off" as of July 2000. Please become familiar with your GPS unit's method of determining error. Some of the lower cost models do not have this ability. If using one of those, insert N/A in this field.

UTM field reading: Easting (UTME) and northing (UTMN) location coordinates using the Universal Transverse Mercator (UTM) grid. Record UTMs using a GPS unit (preferred) or In-House Topographic Field Maps.

UTM zone: Universal Transverse Mercator zone. Zone is 11 for all of SAMO.

Elevation: Recorded from the GPS unit or USGS topographic map. Please denote feet (ft) or meters (m), and note if reading is from GPS unit or map. (Please note: Readings taken from a GPS unit can be hundreds of feet off.)

Photograph #'s: Note the roll number, frame number, direction, and the name of the person whose camera is being used. Take at least two photographs from different directions, and describe the location and view direction from compass bearings for each frame. Additional photographs of the stand may also be helpful.

Topography: Check two of the provided features, characterizing both the local relief and the broad topographic position of the area. First assess the minor topographic features or the lay of the area (*e.g.* surface is flat, concave, etc.). Then assess the broad topographic feature or general position of the area (*e.g.* stand is at the bottom, lower (1/3 of slope), middle (1/3 of slope), upper (1/3 of slope), or top). . In general, this should describe both the entire stand and the Releve plot as the releve location should represent the overall conditions of the stand.

Geology: Geological parent material of site. If exact type is unknown, use a more general category (*e.g.* igneous, metamorphic, and sedimentary). *See code list for types.*

Soil: Record soil texture or series that is characteristic of the site (*e.g.* sand, silt, clay, coarse loamy sand, sandy clay loam, saline, etc.). *See soil texture key and code list for types.*

% Large Rock (optional): Estimate the percent surface cover of large rocks (e.g. stones, boulders, bedrock) that are beyond 25 cm in size.

% Small Rock (optional): Estimate the percent surface cover of small rocks (e.g. gravel, cobbles) that are greater than 2 mm and less than 25 cm in size.

% Bare/Fines (optional): Estimate the percent surface cover of bare ground and fine sediment (e.g. dirt) that is 2 mm or less in size.

% Litter (optional): Estimate the percent surface cover of organic litter.

General slope exposures (circle one and enter actual º): Read degree aspect from a compass (or estimate), using degrees from true north (adjusting for declination). Make sure to average the reading across entire stand. "Variable" may be selected if the same, homogenous stand of vegetation occurs across a varied range of slope exposures. In general, this should describe both the entire stand and the Releve plot as the releve location should represent the overall conditions of the stand.

General slope steepness (circle one and enter actual º): Read degree slope from compass or clinometer (or estimate). Average the reading over entire stand. In general, this should describe both the entire stand and the Releve plot as the releve location should represent the overall conditions of the stand.

Upland or Wetland (circle one): Indicate if the stand is an upland or a wetland; note that a site need not be officially delineated as a wetland to qualify as such in this context (*e.g.* seasonally wet meadow).

Site history, stand age, and comments: Briefly describe the stand age/serial stage, disturbance history, nature and extent of land use, and other site environmental and vegetation factors. Examples of disturbance history: fire, landslides, avalanching, drought, flood, animal burrowing, or pest outbreak. Also, try to estimate year or frequency of disturbance. Examples of land use: grazing, timber harvest, or mining. Examples of other site factors: exposed rocks, soil with fine-textured sediments, high litter/duff build-up, multi-storied vegetation structure, or other stand dynamics.

Type / level of disturbance (use codes): List codes for potential or existing impacts on the stability of the plant community. Characterize each impact each as L (=Light), M (=Moderate), or H (=Heavy). *See code list for impacts.*

VEGETATION DESCRIPTION

Basic alliance and stand description.

Field-assessed vegetation alliance name: Name of alliance (series) or habitat following the CNPS classification system (Sawyer and Keeler-Wolf 1995). Please use binomial nomenclature, *e.g. Quercus agrifolia* forest. An alliance is based on the dominant (or diagnostic) species of the stand, and is usually of the uppermost and/or dominant height stratum. A dominant species covers the greatest area (and a diagnostic is consistently found in some vegetation types but not others).

Please note: The field-assessed alliance name may not exist in present classification, in which you can provide a new alliance name in this field.

Field-assessed association name (optional): Name of the species in the alliance and additional dominant/diagnostic species from any strata, as according to CNPS classification. In following naming conventions, species in differing strata are separated with a slash, and species in the uppermost stratum are listed first (*e.g. Quercus agrifolia/Toxicodendron diversilobum*). Species in the same stratum are separated with a dash (*e.g. Quercus agrifolia-Quercus kelloggii).*

Please note: The field-assessed association name may not exist in present classification, in which you can provide a new association name in this field.

Size of stand: Estimate the size of the entire stand in which the rapid assessment is taken. As a measure, one acre is about 0.4 hectares or about 4000 square meters.

Number of encounters of this alliance (tally/circle once): This estimate can be done for a landscape-level project of a general area, ecological subsection, watershed, etc., though it is not required. Make an estimate of the total number of times that this alliance was seen in the project survey and recorded on field forms.

Please note: This estimation should only be done once, at the end of a project survey, for every alliance identified in the field. Please provide the tally once for each alliance, and provide the estimate on the first rapid assessment field form that was filled out for each alliance.

Habitat classification per California Wildlife-Habitat Relationships (CWHR)

For CWHR, identify the size/height class of the stand using the following tree, shrub, and/or herbaceous categories. These categories are based on functional life forms.

Tree: Circle one of the tree size classes provided when the tree canopy closure exceeds 10 percent of the total cover (except in desert types), or if young tree density indicates imminent tree dominance. Size class is based on the average dbh (diameter of trunk at breast height). In choosing a size class, make sure to estimate the mean diameter of all trees over the entire stand. Circle the size class 6 multi-layered tree if there is a size class 5 of trees over a distinct layer of size class either 3 or 4 (*i.e.*, distinct height class separation between different tree species) and the total tree canopy exceeds 60%.

If tree, list 1-3 dominant overstory species: If tree canopy cover exceeds 10 percent (except in desert types), please list the dominant species that occur in the overstory canopy.

Shrub: Circle one of the shrub size classes provided when shrub canopy closure exceeds 10 percent (except in desert types). Size class is based on the average amount of crown decadence (dead standing vegetation on live shrubs when looking across the crowns of the shrubs).

Herbaceous: Circle one of the herb height classes provided when herbaceous cover exceeds 2 percent. This height class is based on the average plant height at maturity.

Desert Palm/Joshua Tree: Circle one of the palm or Joshua tree size classes by averaging all the stem-base diameters (*i.e.*, mean diameter of all stem-base sizes). Diameter is measured at the plant's base above the bulge near the ground.

Desert Riparian Tree/Shrub: Circle one of the size classes by measuring mean stem height (whether tree and/or shrub stand).

Overall cover of vegetation

Provide an ocular estimate of cover for the following categories (based on functional life forms). Record a specific number for the total aerial cover or "bird's-eye view" looking from above for each

category, estimating cover for the living plants only. Litter/duff should not be included in these estimates.

To come up with a specific number estimate for percent cover, first use to the following CWHR cover intervals as a reference aid to get a generalized cover estimate: <2%, 2-9%, 10-24%, 25-39%, 40-59%, 60-100%. While keeping these intervals in mind, you can then refine your estimate to a specific percentage for each category below.

%Overstory Conifer/Hardwood Tree cover: The total aerial cover (canopy closure) of all live tree species that are specifically in the overstory or are emerging, disregarding overlap of individual trees. Estimate conifer and hardwood covers separately. Please note: These cover values should not include the coverage of suppressed understory trees.

Shrub cover: The total aerial cover (canopy closure) of all live shrub species, disregarding overlap of individual shrubs.

Ground cover: The total aerial cover (canopy closure) of all herbaceous species, disregarding overlap of individual herbs.

Total Veg cover: The total aerial cover of all vegetation. This is an estimate of the absolute vegetation cover, disregarding overlap of the various tree, shrub, and/or herbaceous layers.

Modal height for conifer/hardwood tree, shrub, and herbaceous categories (optional)

If height values are important in your vegetation survey project, provide an ocular estimate of height for each category listed. Record an average height value, estimating the modal height for each group. Use the following height intervals and record a height class: 01=<1/2m, 02=1/2-1m, 03=1-2m, 04=2-5m, 05=5-10m, 06=10-15m, 07=15-20m, 08=20-35m, 09=35-50m, 10=>50m.

Species list and coverage: This Section should be skipped when performing a Releve. An extended table is provided on the back of the sheet.

Species (List up to 12 major species), Stratum, and Approximate % cover: (Jepson Manual nomenclature please) **Major nonnative species in stand (with % cover), Unusual species.** If using form for a releve, this information is filled out in a separate table. See Releve Info below.

PROBLEMS WITH INTERPRETATION

Confidence in Identification: (L, M, H) With respect to the "field-assessed alliance name", note whether you have L (=Low), M (=Moderate), or H (=High) confidence in the interpretation of this

alliance name. Low confidence can occur from such things as a poor view of the stand, an unusual mix of species that does not meet the criteria of any described alliance, or a low confidence in your ability to identify species that are significant members of the stand.

Other identification problems (describe): Discuss any further problems with the identification of the assessment (*e.g.* stand is observed with an oblique view using binoculars, so the species list may be incomplete, or the cover percentages may be imperfect).

Polygon is more than one type (Yes, No) (Note: type with greatest coverage in polygon should be entered in above section) This is relevant to areas that have been delineated as polygons on aerial photographs for a vegetation-mapping project. In most cases the polygon delineated is intended to represent a single stand, however mapping conventions and the constraints and interpretability of remote images will alter the ability to map actual stands on the ground. "Yes" is noted when the polygon delineated contains the field-assessed alliance and other vegetation type(s), as based on species composition and structure. "No" is noted when the polygon is primarily representative of the field-assessed alliance.

Other types: If "Yes" above, then list the other subordinate vegetation alliances that are included within the polygon. List them in order of their amount of the polygon covered.

Has the vegetation changed since air photo taken? (Yes, No) If an aerial photograph is being used for reference, evaluate if the stand of the field-assessed alliance has changed as a result of disturbance or other historic change since the photograph was taken.

If Yes, how? What has changed (write N/A if so)**?** If the photographic signature of the vegetation has changed (*e.g.* in structure, density, or extent), please detail here.

RELEVE INFO: This section is only for Releve use.

Plot Length (m): Record the long axis of the Releve plot in meters.

Plot Width: Record the short axis of the Releve plot in meters.

If circle, diam: If the Releve plot is a circle, record the diameter in meters.

Plot Permanent? If the Releve plot is marked permanently with rebar, etc, circle Y (yes).

Representativeness of plot in stand: Does this plot represent the full variability of the polygon? If not, were additional plots taken? Note additional species not seen in plot in the space provided below. You may also include notes about how this polygon compares to others you have seen of similar type.

Species Table (Releve)

This is found on the backside of the form. At the top of the page, be sure to fill out polygon/stand #, Air photo, and the number of pages the species list is on. List the species that are dominant or that are characteristically consistent throughout the plot.

When different layers of vegetation occur in the plot, make sure to list species from each stratum. As a general guide, make sure to list at least 1-2 of the most abundant species per stratum. Check a stratum code for each species listed, based on height, where T (=Tall) is >5 m in height, M (=Medium) is between 0.5 and 5 m in height, and L (=Low) is <0.5 m in height. Note that you may list the same species in more than one strata, based on the maximum height of the individuals, thus, those canopy tree-sized individuals should only be listed in the canopy tree category and those herb-size individuals should only be listed in the H layer.

For plots with trees, list the DBH (in cm) of all trees above 10 cm diameter (this would include each stem from a multi-stemmed tree). Separate the measurements with a comma. For plots with very high tree density DBH measurements will be done in a subplot. If the number of trees with a DBH greater than 10 cm is more than about 25, divide the plot into quarters and measure the DBH of trees in the most representative quadrant. CLEARLY NOTE on the form that this is what you've done.

Provide a numerical ocular estimate of aerial coverage for each species. When estimating, it is often helpful to think of coverage in terms of the cover intervals (see below). Record the cover class, and then refine your estimate to a specific percentage (*e.g.* the cover of species "x" is somewhere between 25 and 50 percent, but I think it is actually around 30%). Please note: All estimates are to be reported as absolute cover (not relative cover), and all the species percent covers may total over 100% when added up because of overlap.

Cover Scale for Species Percent Cover

Code	Range of Class	Class midpoint
01	>0-1%	0.5%
02	1-5%	3%
03	5-25%	15%
04	25-50%	37.5%
05	50-75%	62.5%
06	75-100	87.5%

VEGETATION RAPID ASSESSMENT / RreleVE FIELD FORM

(Revised April 23, 2003--SAMO)

Accuracy Assessment Protocol
Santa Monica Mountains NRA

Updated: August 11, 2004

Accuracy Assessments (AAs) are gathered to assess the accuracy and calibration level of the mapping units assigned to each polygon. AAs focus on the drawn polygon more than the actual stand.

Choose stands of which you have a good, representative view. Do not choose to AA a polygon that you can only see part of or ones that seem to be transitional. AAs need to be representative of all the diversity of mapped vegetation units in the entire mapping area, much like Rapid Assessments and Releves. A regularly-updated tracking matrix will be provided to the field crews to help insure spread of AAs across SAMO mapping area.

Definitions of Data Fields:

IDENTIFIERS/LOCATORS

Field Point Number: Number assigned to polygon. Each team has been provided with a list of consecutive numbers to be assigned to AA point. Select the next available number and be sure to label the location on the paper copy of the field overlay.

Air Photo: The number given to the aerial photo in a vegetation-mapping project.

Date: Date of the sampling.

Surveyors: The full names of each person assisting should be provided for their first accuracy assessment. In successive assessments, initials of each person assisting can be recorded. Please note: The person recording the data on the form should circle their name/initials.

Park Site Name: Provisional name assigned by field worker that describes where the data were collected. It should represent an identifiable feature on a topographic map.

Quad Code: Appropriate name/scale from survey map used; use 7.5-minute quadrangle if possible. May often be found on photo overlay.

Primary Veg Assoc Name: Using the Vegetation Type Classification Key, assign the best-fitting Association name. Also record the 4-digit mapping code. If Classification Key is not completed, record best guess under Classification Comments.

Secondary Veg Assoc Name: Using the Vegetation Type Classification Key, assign the second-best-fitting Association name. Also record the 4-digit mapping code. If Classification Key is not completed, record best guess under Classification Comments.

Other Veg Assocs within 50m: Record the direction/location and the names of vegetation associations within 50 meters of polygon, as you see them onsite. This is used to double-check location of polygon surveyed.

Classification Comments: Does it key easily using the Vegetation Type Classification Key? Are all diagnostic species present in proper proportions? In not, how do they differ?

GPS File Name: The waypoint number assigned by a Global Positioning System (GPS) unit when marking and storing a waypoint for the stand location. These waypoints can be downloaded from the GPS into a computer Geographic Information System to depict sample points accurately on a map.

GPS Unit: The name personally assigned to each GPS unit (especially useful if more than one GPS unit is used to mark waypoints for the project).

GPS datum: (NAD 27) The map datum that is chosen for GPS unit to document location coordinates. The default datum for CNPS projects as well as SAMO projects is NAD 27. Please circle NAD27 or write in the appropriate datum.

Is GPS within stand? Yes / No Circle"Yes" to denote that the GPS waypoint was taken directly within or at the edge of the stand being assessed, or circle "No" to denoted the waypoint was taken at a distance from the stand (such as with a binocular view of the stand).

If No cite distance (note ft/m), bearing and view from point to stand: An estimate of the number of feet or meters (please circle appropriate), the compass bearing from the waypoint of GPS to the stand, and the method of view used to verify the plot (*e.g*. binoculars, aerial photo).

Error: ± The accuracy of the GPS location, when taking the UTM field reading. Please denote feet (ft) or meters (m). It is typical for all commercial GPS units to be accurate to within 5 m (or 16 ft.) of the actual location because the military's intentional imprecision (known as "selective availability") has been "turned off" as of July 2000. Please become familiar with your GPS unit's method of determining error. Some of the lower cost models do not have this ability. If using one of those, insert N/A in this field.

UTM field reading: Easting (UTME) and northing (UTMN) location coordinates using the Universal Transverse Mercator (UTM) grid. Record UTMs from a GPS unit (preferred) or In-House Topographic Field Maps.

UTM zone: Universal Transverse Mercator zone. Zone is 11 for all of SAMO.

Corrected UTM: Not to be filled out in field.

ENVIRONMENTAL DESCRIPTION

Elevation: Recorded from the GPS unit or USGS topographic map. Please denote feet (ft) or meters (m), and note if reading is from GPS unit or map. (Please note: Readings taken from a GPS unit can be hundreds of feet off.)

General slope exposures (circle one and enter actual º): Read degree aspect from a compass (or estimate) using degrees from true north (adjusting for declination).. Make sure to average the reading across entire stand. "Variable" may be selected if the same, homogenous stand of vegetation occurs across a varied range of slope exposures.

General slope steepness (circle one and enter actual º): Read degree slope from compass or clinometer (or estimate), Average the reading over entire stand.

Topography: Check two of the provided features, characterizing both the local relief and the broad topographic position of the area. First assess the minor topographic features or the lay of the area (*e.g.* surface is flat, concave, etc.). Then assess the broad topographic feature or general position of the area (*e.g.* stand is at the bottom, lower (1/3 of slope), middle (1/3 of slope), upper (1/3 of slope), or top).

Environmental Comments: Include comments on hydrology and fire history. Has the vegetation in polygon changed since photos?

Unvegetated Surface: Use the cover scale below to record % cover of Large rocks, Small rocks, Bare/Fine, Litter.

VEGETATION DESCRIPTION

Leaf phenology (of dominant stratum): Select the value which best describes the leaf phenology of the dominant stratum. The dominant stratum is the uppermost stratum that contains at least 10% cover.

EVERGREEN - Greater than 75% of the total woody cover is never without green foliage.

COLD-DECIDUOUS - Greater than 75% of the total woody cover sheds its foliage in connection with an unfavorable season mainly characterized by winter frost.

DROUGHT DECIDUOUS - Greater than 75% of the total woody cover sheds its foliage in connection with an unfavorable season mainly characterized by drought.

MIXED EVERGREEN - COLD-DECIDUOUS - Evergreen and deciduous species generally contribute 25-75% of the total woody cover. Evergreen and cold-deciduous species admixed.

MIXED EVERGREEN - DROUGHT DECIDUOUS - Evergreen and deciduous species generally contribute 25-75% of the total woody cover. Evergreen and drought-deciduous species admixed.

PERENNIAL - Herbaceous vegetation composed of more than 50% perennial species.

ANNUAL - Herbaceous vegetation composed of more than 50% annual species.

Leaf Type: Select one value which best describes the leaf form of the dominant stratum. The dominant stratum is the uppermost stratum that contains at least 10% cover.

BROAD-LEAVED - Woody vegetation primarily broad-leaved (generally contributes greater than 50 percent of the total woody cover).

NEEDLE-LEAVED - Woody vegetation primarily needle-leaved (generally contributes greater than 50 percent cover).

MICROPHYLLOUS - Woody cover primarily microphyllous.

GRAMINOID - Herbaceous vegetation composed of more than 50 percent graminoid/stipe leaf species.

FORB (BROAD-LEAF-HERBACEOUS) - Herbaceous vegetation composed of more than 50% broad-leaf forb species.

PTERIDOPHYTE - Herbaceous vegetation composed of more than 50 percent species with frond or frond-like leaves.

PHYSIOGNOMIC CLASS CHOOSE ONE:

FOREST: Trees with their crowns overlapping (generally forming 60-100% cover).

WOODLAND: Open stands of trees with crowns not usually touching (generally forming 25-60% cover). Canopy tree cover may be less than 25% in cases where it exceeds shrub, dwarf-shrub, herb, and nonvascular cover, respectively.

SHRUBLAND: Shrubs generally greater than 0.5 m tall with individuals or clumps overlapping to not touching (generally forming more than 25% cover, trees generally less than 25% cover). Shrub cover may be less than 25% where it exceeds tree, dwarf-shrub, herb, and nonvascular cover, respectively. Vegetation dominated by woody vines is generally treated in this class.

DWARF-SHRUBLAND: Low-growing shrubs usually under 0.5 m tall. Individuals or clumps overlapping to not touching (generally forming more than 25% cover, trees and tall shrubs generally less than 25% cover). Dwarf-shrub cover may be less than 25% where it exceeds tree, shrub, herb, and nonvascular cover, respectively.

HERBACEOUS: Herbs (graminoids, forbs, and ferns) dominant (generally forming at least 25% cover; trees, shrubs, and dwarf-shrubs generally with less than 25% cover). Herb cover may be less than 25% where it exceeds tree, shrub, dwarf-shrub, and nonvascular cover, respectively.

NONVASCULAR: Nonvascular cover (bryophytes, non-crustose lichens, and algae) dominant (generally forming at least 25% cover). Nonvascular cover may be less than 25% where it exceeds tree, shrub, dwarf-shrub, and herb cover, respectively.

SPARSE VEGETATION: Abiotic substrate features dominant. Vegetation is scattered to nearly absent and generally restricted to areas of concentrated resources (total vegetation cover is typically less than 25% and greater than 0%).

Strata/Lifeform, Height, Cover, Diagnostic Species: Visually divide the community into vegetation layers (strata). Indicate the average height class of the stratum in the first column, using the Height Scale on the form. Enter the average percent cover class of the whole stratum in the second column, using the Cover Scale on the form. Height and Cover classes are also listed below.

List the *dominant* species and individual cover classes in each stratum. If species known to be diagnostic of a particular vegetation type are present, list these as well, marking them with an asterisk. Only note species of the dominant vegetation type. *Do not list species found in inclusions* (small patches in polygon of different vegetation types).

Note: All AA's collected before August 11, 2004, included all species found in inclusions in the species list in an effort to describe the entire mapping polygon.

Heterogeneity: Choose the one that best describes the heterogeneity of the polygon.

HOMOGENEOUS: a map unit with at least 85% of the area composed of a homogenous condition of vegetation (at the appropriate level in the classification hierarchy) or dominance types

COMPOSED OF SIMILAR TYPES: a map unit composed of a grouping of vegetation or dominance types (at the appropriate level in the classification hierarchy) with similar taxonomic composition and physiognomy. For example, a complex of scrub oak pure and scrub oak - interior oak patterns something different at the fine scale but is closely related in the vegetation classification.

COMPOSED OF DISSIMILAR TYPES: a map unit composed of a grouping of dissimilar vegetation types (at the appropriate level in the classification hierarchy) that are spatially and ecologically related on the landscape. For example, a small herbland and adjacent rock outcroppings complexing in a small area.

Inclusions: List the vegetation type of any inclusions found within the mapping polygon and the percent of the polygon composed of them. Additional descriptions of the inclusions such as location can be entered under *AA Comments*.

Cover Scale 1:

01	0-5%
02	>5-10%

Observation Protocol
Santa Monica Mountains NRA

June 11, 2003

The observation form has been developed as a way to efficiently provide photointerpretors with basic information on specified polygons. The photointerpretors do not always need the complete information of a Rapid Assessment but rather a quick confirmation or check of a photo signature. This form in combination with the Priority Categories listed below significantly speeds and focuses data collection.

The use of this form is up to the discretion of the field crew. If you feel the additional information in an RA would be very helpful to AIS, perform an RA. *Crews do not have to fill out form completely for each polygon* depending information needed and how close AIS is to correct code.

Remember to label these on the RA sheets so that other teams know information has already been gathered there.

Definitions of Data Fields

Air photo #: The number given to the aerial photo in a vegetation-mapping project, for which photointerpreters have already done photointerpretation and delineations of polygons. If the sample site has not been photo-interpreted, leave blank. Data from only one air photo should be recorded on the same observation sheet.

Date(s): Date(s) of the sampling.

Name(s) of surveyors: Initials of each person assisting can be recorded.

Polygon/Stand #: Number assigned either in the field or in the office prior to sampling.

Initial AIS Code: 4-digit mapping classification code assigned by AIS at time of initial interpretation.

Field Crew Code: 4-digit code mapping classification code assigned by Field crew upon completion of form. This should correspond as closely as possible to the Field Alliance and Association Name (see below).

Confidence in Identification: (L, M, H) With respect to the "field-assessed alliance name", note whether you have L (=Low), M (=Moderate), or H (=High) confidence in the interpretation of this alliance name. Low confidence can occur from such things as a poor view of the stand, an unusual mix of species that does not meet the criteria of any described alliance, or a low confidence in your ability to identify species that are significant members of the stand.

Problems (describe): Discuss any further problems with the identification of the assessment (*e.g.* stand is observed with an oblique view using binoculars, so the species list may be incomplete, or the cover percentages may be imperfect).

General slope exposures (circle one and enter actual º): Read degree aspect from a compass (or estimate), using degrees from true north (adjusting for declination). Make sure to average the reading across entire stand. "Variable" may be selected if the same, homogenous stand of vegetation occurs across a varied range of slope exposures. In general, this should describe both the entire stand and the Releve plot as the releve location should represent the overall conditions of the stand.

General slope steepness (circle one and enter actual º): Read degree slope from compass or clinometer (or estimate). Average the reading over entire stand. In general, this should describe both the entire stand and the Releve plot as the releve location should represent the overall conditions of the stand.

Bino Assessed Only? (circle one): If the polygon was only viewed through binoculars and was not entered into, circle yes.

Site history, stand age, and comments: Briefly describe the stand age/serial stage, disturbance history, nature and extent of land use, and other site environmental and vegetation factors. Also include any other notes that may be of help to photointerpretors.

Field-assessed alliance/association: Name of alliance (series) or association following the CNPS classification system (Sawyer and Keeler-Wolf 1995). Please use binomial nomenclature, *e.g.* *Quercus agrifolia* forest. An alliance is based on the dominant (or diagnostic) species of the stand, and is usually of the uppermost and/or dominant height stratum. A dominant species covers the greatest area (and a diagnostic is consistently found in some vegetation types but not others).

Please note: The field-assessed alliance or assocation name may not exist in present classification, in which you can provide a new alliance name in this field.

%Overstory Conifer/Hardwood Tree cover: The total aerial cover (canopy closure) of all live tree species that are specifically in the overstory or are emerging, disregarding overlap of individual trees. Estimate conifer and hardwood covers separately. Please note: These cover values should not include the coverage of suppressed understory trees.

Shrub cover: The total aerial cover (canopy closure) of all live shrub species, disregarding overlap of individual shrubs.

Ground cover: The total aerial cover (canopy closure) of all herbaceous species, disregarding overlap of individual herbs.

Total Veg cover: The total aerial cover of all vegetation. This is an estimate of the absolute vegetation cover, disregarding overlap of the various tree, shrub, and/or herbaceous layers.

Species list and coverage

Species (List up to 6 major species), Stratum, and Approximate % cover: (Jepson Manual nomenclature please)

List the species that are dominant or that are characteristically consistent throughout the stand.

When different layers of vegetation occur in the stand, make sure to list species from each stratum. As a general guide, make sure to list at least 1-2 of the most abundant species per stratum. Provide a stratum code for each species listed, based on height, where T (=Tall) is >5 m in height, M (=Medium) is between 0.5 and 5 m in height, and L (=Low) is <0.5 m in height.

Also, provide a numerical ocular estimate of aerial coverage for each species. All estimates are to be reported as absolute cover (not relative cover), and all the species percent covers may total over 100% when added up because of overlap.

Other Notes: At bottom of the form, record additional notes about specific polygons or about photo in general. For example: There is no *Malosma laurina* in area, only *Rhus ovata*.

WIKIPEDIA

Juglans californica

Juglans californica, the **California black walnut**, also called the **California walnut**, or the **Southern California black walnut**, is a large shrub or small tree (up to 30 feet tall) of the walnut family, Juglandaceae, endemic to California.

Contents

Distribution

Description

Uses

- Food
- Cultivation

Taxonomy

Further reading

External links

Distribution

Juglans californica is generally found in the southern California Coast Ranges, Transverse Ranges, and Peninsular Ranges, and the Central Valley. It grows as part of mixed woodlands, and also on slopes and in valleys wherever conditions are favorable. It is threatened by development and overgrazing. Some native stands remain in urban Los Angeles in the Santa Monica Mountains and Hollywood Hills. ***J. californica*** grows in riparian woodlands, either in single species stands or mixed with California's oaks (***Quercus*** spp.) and cottonwoods (***Populus fremontii***).

Description

Juglans californica can be either a large shrub with 1–5 trunks, or a small, single-trunked tree. The main trunk can fork close to the ground, making it look like two trees that have grown together, then diverged. It has thick bark, deeply channeled or furrowed at maturity. It has large, pinnately compound leaves with 11–19 lanceolate leaflets with toothed margins and no hair in the vein angles.[2] It has a small hard nut in a shallowly grooved, thick shell that is difficult to remove.

Uses

Juglans californica

California black walnut
Conservation status

Vulnerable (IUCN 2.3)
Scientific classification
Kingdom: Plantae
Clade: Angiosperms
Clade: Eudicots
Clade: Rosids
Order: Fagales
Family: Juglandaceae
Genus: Juglans
Section: Juglans sect. Rhysocaryon
Species: J. californica
Binomial name
Juglans californica S. Wats.[1]

Food

The Chumash Indians of the Channel Islands of California and Ventura County eat the nuts; however, they are not grown commercially for this purpose.

Cultivation

Juglans californica is cultivated throughout California to support the walnut industry, used as a rootstock in English walnut orchards. It is also cultivated as an ornamental tree where it is planted in California native plant, xeriscape, and wildlife habitat gardens and natural landscaping in California, and in Hawaii.

Natural range

Taxonomy

Some authorities (e.g. the California Native Plant Society) combine this species with ***J. hindsii***. On the other hand, a 2007 molecular analysis of the genus[3] suggests ***J. californica*** is sister to the remaining black walnuts (section Rhysocaryon). This article follows the conventions of ***The Jepson Manual***.[4][5]

Re: CEQA Appeal for 11472 West Laurelcrest Drive, Los Angeles, California; CF 19-1134

Dear Council President Martinez and Councilmembers:

This firm represents Sunshine Hill Residence Association ("Appellant" or "Association"). Appellant has cited to a variety of reference materials in the letters submitted to the City thus far. This letter is intended to provide the City with copies of additional cited source documents to ensure that are made part of the Administrative Record. See Exhibits 22-24.

I may be contacted at 310-982-1760 or at jamie.hall@channellawgroup.com if you have any questions, comments or concerns.

Sincerely,

Jamie T. Hall

U.S. Department of the Interior
National Park Service
Natural Resource Stewardship and Science
Fort Collins, Colorado

The National Park Service, Natural Resource Stewardship and Science office in Fort Collins, Colorado, publishes a range of reports that address natural resource topics. These reports are of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate comprehensive information and analysis about natural resources and related topics concerning lands managed by the National Park Service. The series supports the advancement of science, informed decision-making, and the achievement of the National Park Service mission. The series also provides a forum for presenting more lengthy results that may not be accepted by publications with page limitations.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received formal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data, and whose background and expertise put them on par technically and scientifically with the authors of the information.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available in digital format from the Natural Resource Publications Management website. To receive this report in a format optimized for screen readers, please email irma@nps.gov.

Executive Summary

Artificial night lighting represents a growing challenge for managers of parks and protected lands. The disruption of natural patterns of light and dark, which have been more or less reliable for millions of years, has a range of adverse consequences for wildlife across taxonomic groups and landscape types. This document reviews effects of artificial night lighting by habitat type and discusses the approaches available to land managers to mitigate and avoid certain adverse effects of artificial night lighting.

Coastal dunes, beaches, and shorelines are a transition zone between terrestrial and aquatic habitats. They often contain gradients of lighting influence from developed shorelines to darker lakes and oceans. Sea turtles are prominent victims of these disrupted lighting regimes. The foraging decisions of many other species are influenced by lighting conditions, embodying tradeoffs between predation risk and dietary needs.

Deserts and scrublands are open habitats with few barriers to light transmission. They are also often hot in the day, with large proportions of nocturnal and crepuscular species avoiding thermal stress. Many nocturnal desert species prefer low illumination levels and have good visual performance under the faint light of the darkest nights.

Wetlands and rivers are often dark spots surrounded by lights, especially when close to human settlement. Movement of species into and out of wetlands and streams is influenced by lights, as is the movement of animals, such as fishes or aquatic invertebrates, up and down rivers and streams. Downwelling light mediates most predator–prey interactions in the water column. Changing light levels cause predators and prey to change depth. Small prey species are influenced by the phase of the moon, and lighting can degrade conditions favorable to successful foraging. Emerging research demonstrates that lighting influences the developmental rates of wetland organisms such as amphibians.

Islands, oceans, and reefs are increasingly influenced by lights from onshore sources, hydrocarbon extraction platforms, fishing vessels, and all manner of ships. Downwelling light is also a dominant factor in structuring ecosystem processes in marine water columns, and many organisms are sensitive to extremely small changes in light levels. Extensive vertical migrations are driven by changes in surface illumination. Changes in surface lighting can have effects hundreds of meters below the surface. Lighting will alter reproduction and predator–prey interactions, and can attract organisms across wide areas.

Grasslands are also open habitats with few barriers to block lights. Research shows influence of lighting on nesting behavior of birds, distribution of predators, and signaling by bioluminescent organisms such as fireflies.

Deciduous and evergreen forests can block light and reduce its influence, but also contain communities of forest floor species adapted to lighting levels much dimmer than in exposed habitats. Therefore even low levels of light can influence foraging times or timing of reproductive activity.

Alpine and tundra habitats are well represented in protected lands. Many species have annual rhythms designed to avoid the harsh winter that are potentially disrupted by lighting cues. In alpine habitats, the slope of the land potentially exposes habitats to direct glare from downslope sources in addition to light reflected in the atmosphere.

Finally, *urban environments* have many artificial light sources, but still can support significant biodiversity in the form of both resident and migratory species. Migratory birds are attracted to lighted structures at night and collide with windows during the day. Some bat species are attracted to insects found under city lights, while others avoid them.

Mitigation of adverse effects of anthropogenic light in these different habitats is guided in five ways:

1. Need. Creative solutions are often available to avoid use of lights where they are not absolutely necessary. Especially in natural areas, managers should exercise discretion in limiting the lighting infrastructure.
2. Spectrum. Although no color of light is benign in all situations, managers should avoid lights that have ultraviolet or blue light (shorter wavelengths) and in general use lights with red and yellow hues.
3. Intensity. Reducing the intensity of lights can often improve visibility for humans by reducing the contrast between light and shadow, allowing people to see a larger area than they might otherwise be able to discern. Guidelines for lighting intensity from the lighting industry should not be followed when trying to reduce impacts to wildlife, because they are usually higher than necessary for human vision and do not take into account impacts to wildlife.
4. Direction. Lights should be shielded such that they only cast light where it is needed, and never be directed upwards.
5. Duration. Timers and motion detectors can reduce the time a light is on and may therefore reduce impacts. Curfew hours for lights can also enhance visitor experience.

In this report, many lighting situations are considered, including communication towers, night hiking and mountain biking, campsite lighting, off-road vehicles, monuments, light-assisted fishing, security lighting, bridges, roadway lighting, energy production installations, indoor lighting, lighthouses, and billboards. With careful planning and collaboration, usually with nearby jurisdictions, managers of parks and other protected lands can be leaders in the control of light pollution and increase enjoyment of natural lands from inner city parks to wilderness areas.

Introduction

Americans have long recognized that parks and protected lands can provide opportunities to see and enjoy the solitude of unspoiled nature, where the natural rhythms of life are allowed to flourish with minimal influence from humans. Managers of parks and protected lands balance the need to provide visitor facilities with the impacts of such infrastructure on the environment. Although night lighting may be a requirement for visitors in some circumstances, scientific research has documented a range of adverse consequences of night lighting on ecosystems and wildlife. The effects of lighting on species and ecosystems can be reduced, and in some instances avoided altogether. This report provides examples of assessing the impacts of night lighting on wildlife, and presents options to retrofit and design lighting that minimize impacts to wildlife and the nocturnal environment.

Extensive outdoor (and indoor) electric lighting is a recent phenomenon. Thomas Edison commercialized the electric light bulb in the late 1880s, and outdoor use was largely limited to cities until well into the 1900s. Electric lights were introduced in city centers as replacements for gas lamps in the late 1880s, with lethal effects on wildlife. Nearly 1,000 migratory birds were killed in collisions after being attracted to an electric light tower in Decatur, Illinois in 1886 (Gastman 1886). Significant outdoor lighting spread with the rural electrification programs of the 1930s and 1940s. More recently, other significant sources of outdoor lighting have spread across large swaths of the globe, primarily through illumination of human settlements and associated transportation infrastructure. Other sources of artificial night lighting have proliferated as well. Lighting associated with oil and gas development illuminates large terrestrial and offshore regions. Similarly, light-assisted fishing operations illuminate oceans in many regions and oceangoing freighters and passenger ships introduce mobile light sources along oceanic routes. Together, these and other light sources introduce novel lighting conditions that have no historical precedent in natural ecosystems. Natural patterns of darkness are lost or endangered globally (Bennie et al. 2015, Duffy et al. 2015, Marcantonio et al. 2015).

This document is divided into two sections. The first section reviews the effects of artificial night lighting on major habitat types. No single solution can mitigate all adverse effects of artificial night lighting. We therefore attempt to generalize the concerns that typify each biome. The second section provides recommendations for management approaches to minimize impacts from lighting. We address the characteristics of lights in terms of need, spectrum, intensity, direction, and duration, with reference to biomes in which each method of control would be applicable. This discussion addresses common lighting applications — roadways, parking, and walkways — as well as specialized situations like night hiking and mountain biking, vanity lighting, communication towers, and light-assisted fishing.

Effects of Artificial Night Lighting on Natural Ecosystems

Natural patterns of light and dark

In the natural world, sources of light are either very predictable or notably ephemeral. The dominant and structuring source of light is the sun, through daylight and the reflected light of moonlight. Patterns and intensity of sunlight and moonlight vary with geographic location, weather, and time, but they have certain predictable characteristics. For example, the daily, monthly, and seasonal patterns of moonlight and sunlight incident upon the Earth's atmosphere are only rarely interrupted (e.g., by a solar eclipse). Once the sun has set, the brightest possible constant light source is a full moon until the sun rises again (**Figure 1**). The length of the night varies by season and latitude and these patterns are, in the timescale of biological activity, fixed. Weather influences illumination during the day, and does not, with the exception of lightning, increase nocturnal illumination. Fires, lightning, bioluminescence, starlight, airglow, and zodiacal light contribute to nighttime illumination under natural conditions, and these transient sources are brief, rare, or dim in comparison with sunlight and moonlight.

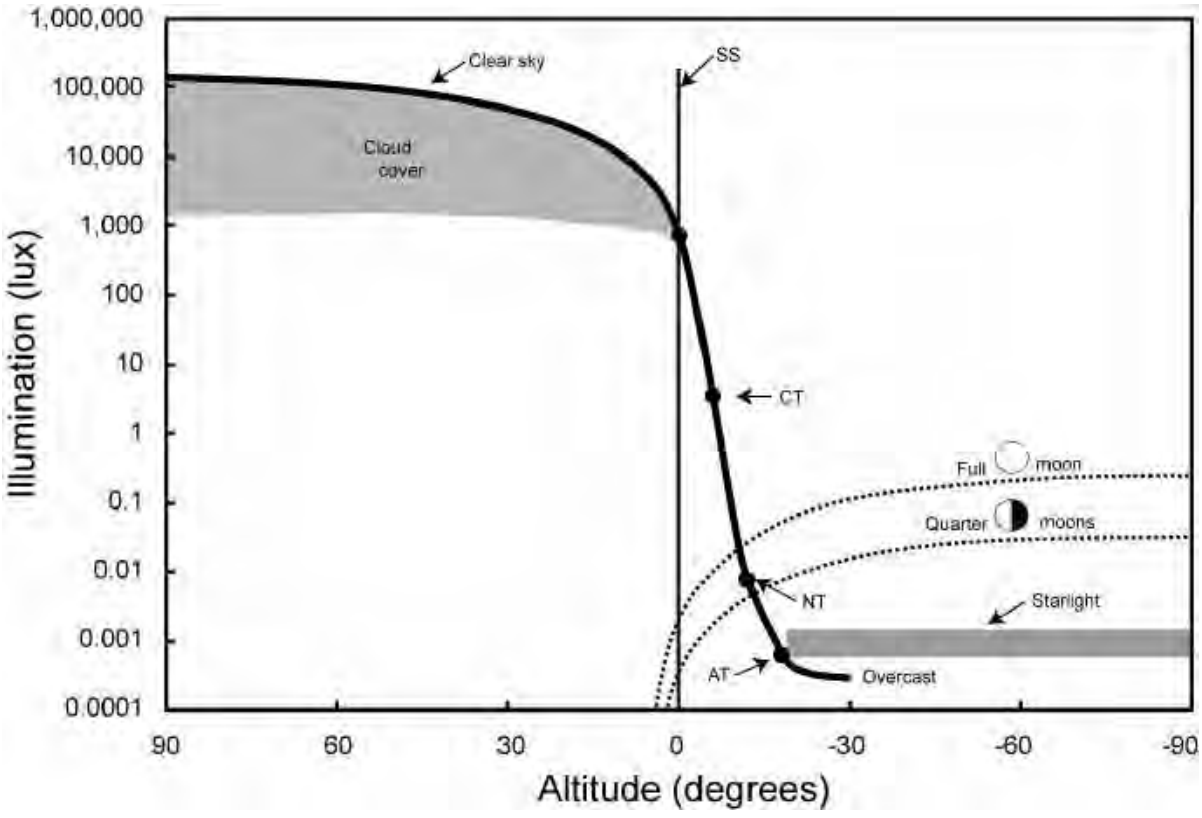

Figure 1. Natural horizontal illumination during the day, sunset, and at night (Beier 2006). Horizontal illumination on the y-axis; x-axis shows altitude above the horizon for the sun and moon. SS = sunset, CT = civil twilight, NT = nautical twilight, AT = astronomical twilight. Modified with permission from Beier (2006) and following Brown (1952).

Light falling on a surface is often measured in lux, a unit of illuminance that sums electromagnetic energy after filtering in accordance with the daytime (photopic) sensitivity of the human eye. Light

emitted from a source is often measured in lumens, a unit of luminance that also accounts for the photopic spectral sensitivity of the human eye. Measurements of lux and lumens place more weight on wavelengths to which the human eye responds most strongly, and less on those wavelengths to which the human eye is less sensitive. Similar measurements can be customized for the optic spectral sensitivities of different species by re-weighting the calculations to emphasize different wavelengths of light (Gal et al. 1999 and **Figure 2**).

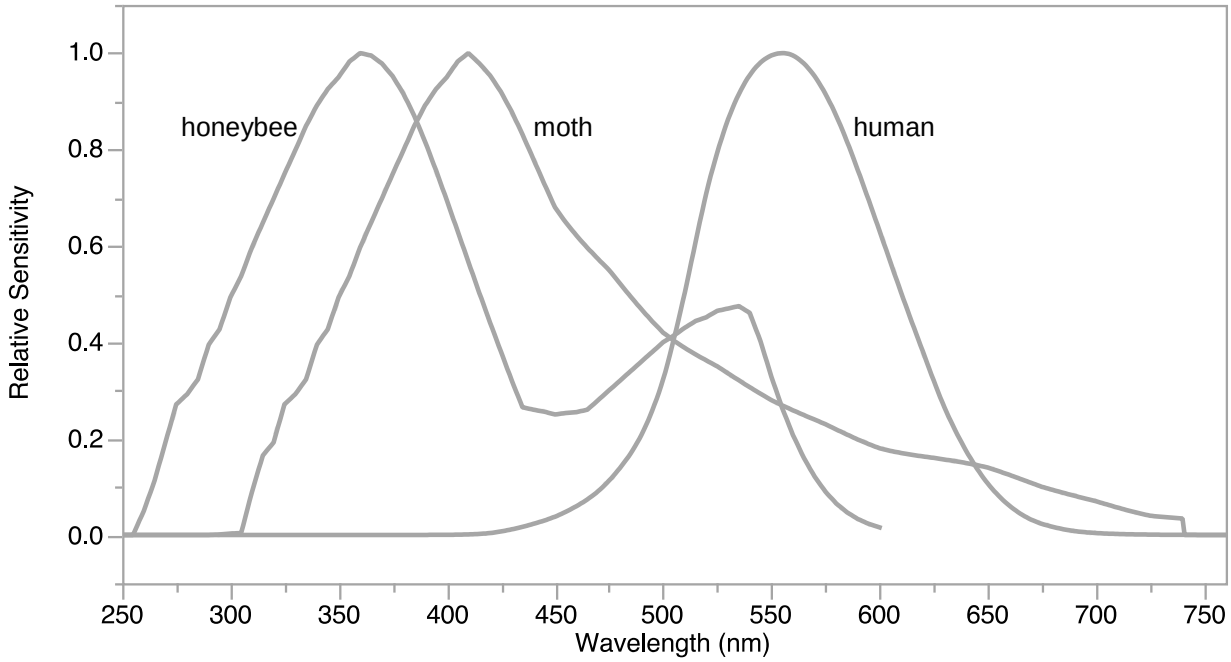

Figure 2. Relative sensitivity to light across the visual spectrum for honeybees (Menzel and Greggers 1985), moths (Cleve 1964), and human photopic vision (CIE 1932).

Outdoor illumination during the day ranges from 100,000 lux in full sunlight to 1,000 lux on a cloudy day (**Figure 1**). Dusk and dawn are transitions into and out of much darker conditions. These transitions are also characterized by predictable changes in the relative intensities of the wavelengths of light. As dusk falls, blue light increases, especially when the moon is new or not present. With moonlight, this blue pulse is diminished or absent and moonlight itself is red-shifted relative to sunlight (Sweeney et al. 2011). Airglow is dominated by green light while zodiacal light is reflected sunlight and will track its spectral composition quite closely, although very slightly shifted to the red (Leinert et al. 1998). Variations in illuminance and color trigger many behavioral and physiological processes (Sweeney et al. 2011, Walmsley et al. 2015). Circadian, circannual, and circalunar rhythms are linked to the predictable changes in the light environment. Light triggers can be at different illuminations depending on the environment. What is extraordinarily dim in one environment may be bright in another. For example, the illumination at which activity takes place on a forest floor is on average dimmer than illumination levels triggering the same activity for similar organisms in open grassland. Illumination that is within the natural range of variation on a beach may be far brighter than anything experienced at night at ground level in a dense forest.

Life evolved with predictable daily, monthly, and seasonal patterns of light and dark, and these patterns underlie the natural rhythms of nearly all living organisms. Artificial night lighting has long been known to affect these patterns. Nocturnal species, which represent the majority of some major taxonomic groups (**Figure 3**), are obviously vulnerable, as are diurnal or crepuscular species whose behavioral niches can be distorted by lighting. Concern about adverse effects of lighting dates to descriptions of the "destruction" of birds at lighthouses in the late 1800s (Allen 1880) and even the first electric urban lighting (Kumlien 1888). Mortality of hatchling sea turtles at lights was identified as a conservation issue in the 1960s (McFarlane 1963). Verheijen coined the term *photopollution* in 1985 (Verheijen 1985), which was followed by Ken Frank's classic review of the effects of lighting on moths (Frank 1988), and a series of unpublished reports (Outen 1998), conference proceedings (Schmiedel 2001), and research reports from Europe (De Molenaar et al. 2000, Kolligs 2000). In 2004, we described *ecological light pollution* as "artificial light that alters the natural patterns of light and dark in ecosystems" (Longcore and Rich 2004).

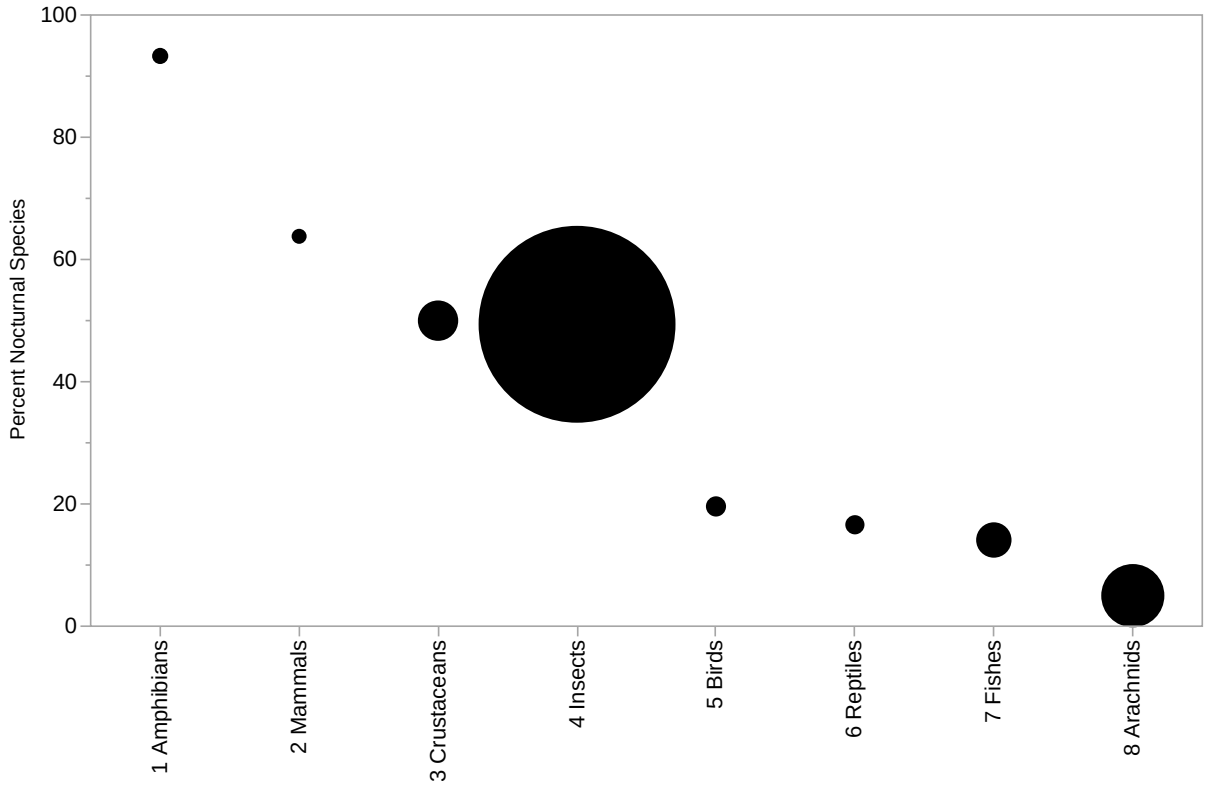

Figure 3. Proportion of major animal groups that are nocturnal. Area of markers is proportional to the number of species known in the group. Data from Hölker et al. (2010).

The disruptions caused by artificial night lighting occur whenever the natural patterns of light and dark are changed. This means that very low lighting levels (far below that of the full moon) can have important effects.

Reviews of the effects of artificial night lighting on different taxonomic groups can be found in Rich and Longcore (2006). Resource managers dealing with questions about specific groups of organisms

should consult this source, which contains chapters on mammals, birds, reptiles and amphibians, fishes, invertebrates, and plants. Taxonomically specific information is essential to devise lighting systems that minimize impacts on sensitive species when lighting is necessary. Sensitive species should be identified relative to a specific area and might include both those species that have a formal designation as being threatened or endangered or any species of concern that would be sensitive to changes in nocturnal illumination. Nocturnal, crepuscular, and diurnal species can be affected by nighttime lighting conditions.

In the sections that follow, we present short reviews of the effects of artificial night lighting in different habitat types.

Coastal dunes, beaches, and shorelines

Coastal dunes and beaches are generally open environments with low vegetation adapted to moving sand (**Figure 4**). Dunes present unique environmental conditions that are often quite distinct from their surroundings, and they are often populated by endemic species that thrive in these unique conditions. Coastal endemic species are often a focus of management concern because of the development pressure on coastal ecosystems in the United States (Schlacher et al. 2007a). Dunes are also ecological transition zones between land and water; light from development in coastal dunes illuminates adjacent water bodies, and animals such as turtles move from water to land to nest. Shorelines are essential for organisms such as amphibians and aquatic insects that have biphasic life cycles.

On a beach or coast under natural conditions, the view toward the land is almost always darker than the view toward the water. This is a function of landward vegetation and topography blocking light from the sky (Salmon 2006), in addition to moonlight and starlight reflected off the water. Organisms can use this pattern for orientation. Artificial lighting on the shore or from cities and other coastal development can reverse the natural conditions; the landward horizon becomes brighter, while the water is darker (Salmon 2006).

Stray light and sky glow from coastal development spread across and into many dune and shoreline environments. As in many environments, nocturnal activity near shorelines is significant (Salmon 2006). Beaches and coasts also regularly experience foggy and high-aerosol conditions, which scatter light and thereby amplify the local effects of lights (Kyba et al. 2011).

Artificial lighting has adverse consequences for sea turtles because the darkest horizon is no longer the landward horizon. Indeed, the lethal effects of lights on sea turtles have led to increased awareness of the adverse effects of artificial night lighting in general. Female sea turtles avoid illuminated beaches as nest sites, and hatchings are fatally affected by lights visible from beaches (Salmon 2003, 2006). This phenomenon was first recorded by MacFarlane (1963), and aversion of females to lights was confirmed experimentally by Witherington (1992). Habitat degradation by lights is caused both by lights adjacent to dunes and beaches and by regional sky glow (Salmon 2006).

Figure 4. Beach environments are vulnerable to the effects of anthropogenic light because of their open nature. Hatchling sea turtles are easily disoriented by onshore lights or sky glow and patterns of nocturnal foraging by shorebirds are also affected.

As a general rule, additional light — whether moonlight or anthropogenic light — increases foraging efficiency of predators and reduces activity of prey (Longcore and Rich 2004, Rich and Longcore 2006, Seligmann et al. 2007). This phenomenon has been shown many times in different habitats. On dunes, Bird et al. (2004) investigated the effects of lighting on foraging behavior of beach mice. Bird et al. (2004) used low-pressure sodium lights and yellow incandescent "bug" lights, which are commonly employed on beaches in Florida because they have limited effects on sea turtle hatchlings. They found that foraging by beach mice was significantly decreased in proximity to both types of turtle-friendly lights. Similar behavior by prey species has been shown for both natural and anthropogenic light. For example, ghost crabs are active only at night, and avoid activity under both the full moon (Schlacher et al. 2007b) and artificial light (Christoffers 1986). The exception to this pattern is that prey species that flock or school together can be aided by additional light that facilitates communal vigilance (Nightingale et al. 2006).

Effects from lights on beaches and shorelines may also affect aquatic ecosystems. For example, lights affect the predator–prey dynamics of fishes and marine mammals (Hobson 1965, Hobson et al. 1981, Yurk and Trites 2000, Nightingale et al. 2006).

Shorebirds sometimes forage at night (Dugan 1981, Burger and Gochfeld 1991, Rohweder and Baverstock 1996). Various explanations have been proposed: as a defense against predation (Robert

et al. 1989, McNeil et al. 1992, Thibault and McNeil 1994), as a result of slightly higher invertebrate activity on beaches at night (Dugan 1981, Evans 1987), and as a response to visual cues that are available due to higher levels of natural or anthropogenic light (Dwyer et al. 2012). Predator defenses of shorebirds are different during the night compared with the day; in an observational study, some proportion of Dunlins freeze and limit vocalizations as a defense at night while all individuals in a flock fly away in response to predators during the day (Mouritsen 1992). Owls are the major nocturnal predator of shorebirds and are aided by additional light when foraging (Clarke 1983). Timing of foraging by shorebirds, therefore, probably depends on tradeoffs between risks of becoming prey with ability to detect their own prey. Whether birds are flocking and have sufficient light for the associated communal predator vigilance probably also interacts with these factors.

Artificial night lighting on dunes and beaches can therefore have a variety of effects on species. Predator–prey relations are disrupted and key reproductive behaviors can be inhibited. Beaches and dunes also provide a gateway to adjacent water bodies, which have no barriers to block the propagation of light. Because there is usually less anthropogenic light at beaches and on shorelines than in surrounding urban or suburban areas, park visitors often use beaches and dunes to gaze at the night sky. Beaches and dunes should be kept as free from the influence of artificial lights as possible, with special attention paid to ensuring that any lights installed are absolutely necessary and that no lights are directly visible from the beach and points offshore.

Deserts and scrublands

Deserts and scrublands are open habitats with few barriers to the spread of light (**Figure 5**). Many animal species in hot deserts and scrublands adopt nocturnal behaviors to conserve water and avoid daytime temperature maxima. This shift to nocturnal activity may increase seasonally with higher temperature (Kronfeld-Schor and Dayan 2008). Consequently, artificial night lighting has the potential to change the ecology of these environments by disrupting the natural patterns of light and dark relied upon by a large proportion of fauna.

Desert animals can have narrow preferences for illumination levels. These preferences may be related to foraging opportunities, predation risk, or physiological requirements. For example, *Leucorchestris arenicola*, a trapdoor spider endemic to the Namib Desert, exhibits exclusively nocturnal activity patterns (Nørgaard et al. 2006). Males are active only during dark moonless nights, when they are able to navigate hundreds of meters across dune environments using only faint ambient light from stars, airglow, and zodiacal light (Nørgaard et al. 2006). For a species such as this, addition of illumination from any source in its habitat would eliminate its preferred habitat conditions.

Desert rodents also exhibit specific illumination preferences to manage their risk of becoming prey (Grigione and Mrykalo 2004, Beier 2006). Some species are active at twilight, others after twilight, and some during the darkest periods of moonless nights (Grigione and Mrykalo 2004, Upham and Hafner 2013). Anthropogenic light can disrupt these patterns; even the light from a camp lantern equivalent to a quarter moon ($\sim 10^{-2}$ lux) was sufficient to substantially inhibit foraging by a suite of rodent species (Kotler 1984). Those species vulnerable to this disruption lack other predator avoidance abilities such as exceptional hearing (Kotler 1984, Kotler 1985). Because many desert

animals exhibit circalunar patterns in their activities, especially predaceous arthropods such as scorpions (Skutelsky 1996, Tigar and Osborne 1999) and granivorous small mammals (Price et al. 1984, Daly et al. 1992, Upham and Hafner 2013), it follows that any artificial light that produces light equivalent to even a quarter moon can alter these patterns.

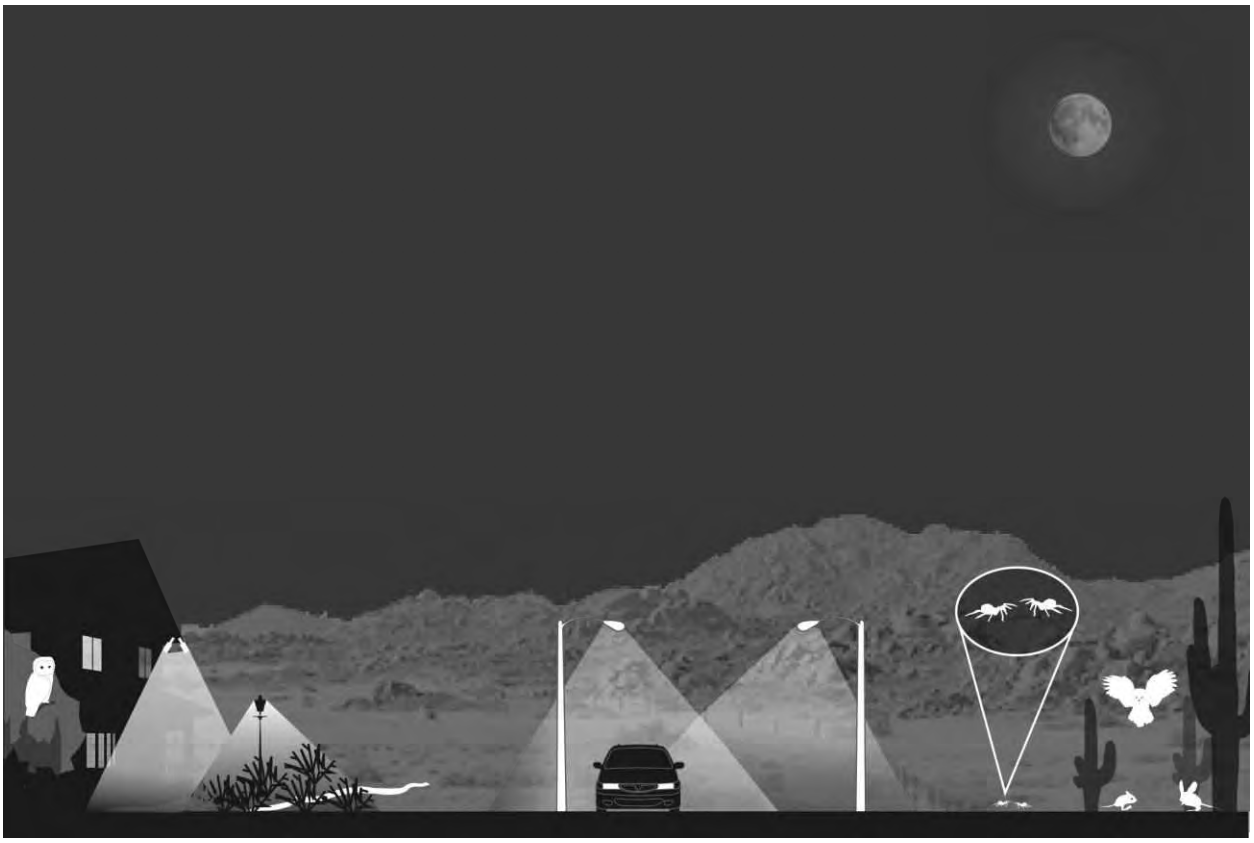

Figure 5. Lights in desert scrublands are visible for long distances and night lighting affects a disproportionate fraction of the wildlife because high daytime temperatures induce nocturnal activity patterns.

Scrubland environments share many characteristics with deserts, especially in Mediterranean climates. A disproportionate number of species is nocturnal at high temperatures, and the open vegetation structure of drier scrublands allows for light to propagate for unusually long distances.

Perry and Fisher (2006) describe the decline of nocturnal snake species in the scrublands of southern California. Long-nosed snake (*Rhinocheilus lecontei*), a nocturnal species, showed a pattern of decline consistent with the gradient of light pollution as estimated by satellite imagery (Fisher and Case, unpub. data). Otherwise suitable scrub habitats, which supported other diurnal species of snakes, lacked long-nosed snakes. The authors hypothesized that decreases in numbers of the snake's small-mammal prey, also associated with light pollution, were responsible for the decline (Perry and Fisher 2006).

Wetlands and rivers

In some places, wetlands and lakes are the last refuges of a natural night on the landscape (**Figure 6**). The difficulty of developing wetlands often leaves them as the only remaining unlighted sites in urban and suburban regions. Many aquatic organisms depend on daily cycles of light and dark and artificial lights disrupt critical behaviors in many species (Moore et al. 2006, Perkin et al. 2011, Henn et al. 2014).

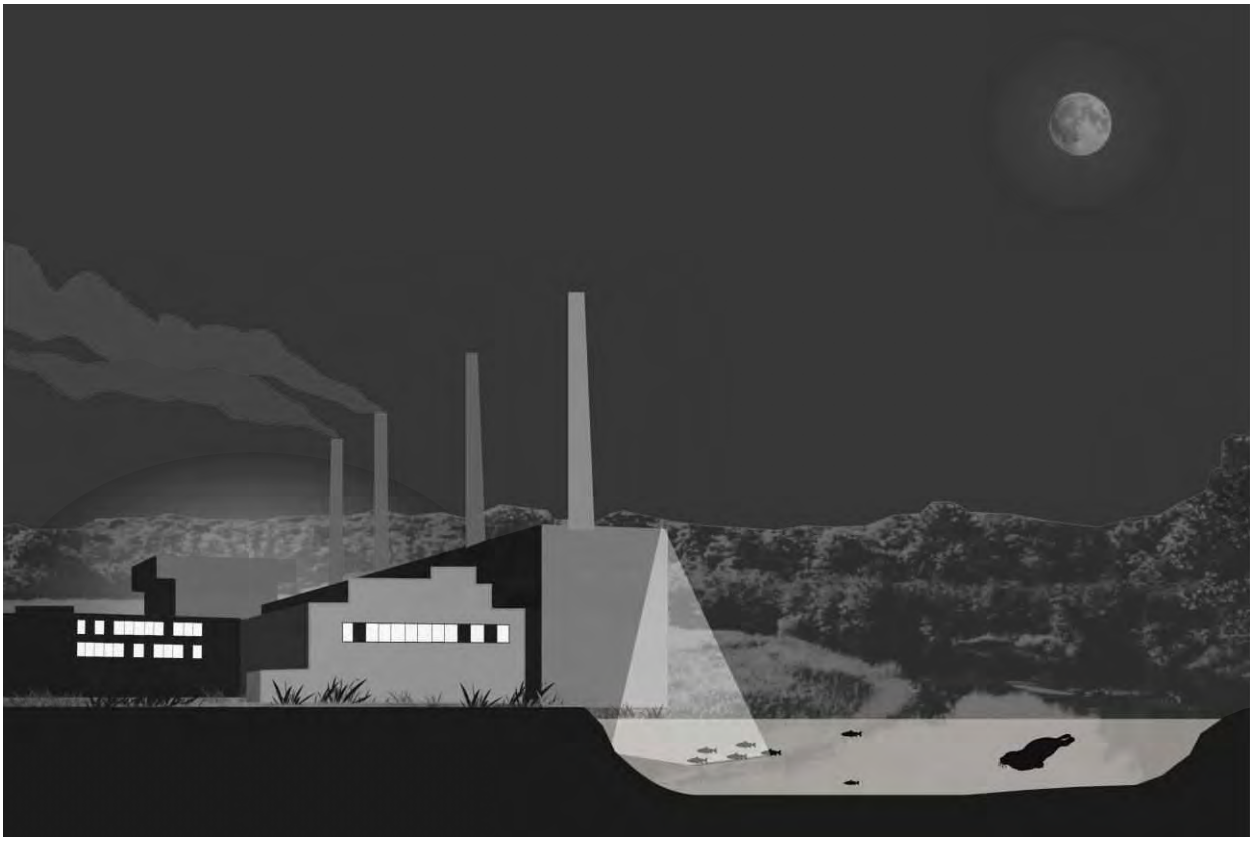

Figure 6. Lights along rivers and streams can disrupt predator–prey interactions, such as seals hunting salmon under lights.

Wetlands are often geographically fragmented, occurring as isolated patches or as linear features stretching across the landscape. Linear features are susceptible to disturbances such as artificial night lighting because they have a high edge-to-area ratio. They also tend to induce development along their edges, which leads to lighting from urban development on either side. Similarly, small wetlands are especially vulnerable to disturbances from their surroundings.

Aquatic invertebrates are important components of wetland ecosystems and provide an example of the sensitivity of wetlands to lighting levels (**Figure 7**). Many aquatic invertebrates migrate up and down in wetlands during the course of a night and day. This "diel vertical migration" presumably results from a need to avoid predation during lighted conditions so many zooplankton forage near water surfaces only during dark conditions. Light dimmer than that of a half moon ($<10^{-1}$ lux) is sufficient to influence the vertical distribution of aquatic invertebrates, and indeed diel vertical

migration follows a lunar cycle. When constant light from human development is added to the natural nocturnal illumination of the moon and stars, the darkest conditions are never experienced, and the magnitude of diel migrations (both range of vertical movement and number of individuals migrating) is decreased, which has been shown experimentally for *Daphnia* (Moore et al. 2000). Disruption of diel vertical migration by artificial lighting may have significant detrimental effects on ecosystem health. Moore et al. (2000) conclude that "[decreases in] vertical migration of lake grazers may contribute to enhanced concentrations of algae in both urban lakes and coastal waters. This condition, in turn, often results in deterioration of water quality (i.e. low dissolved oxygen, toxicity, and odor problems)."

Figure 7. Light in wetlands can suppress diel vertical migration of zooplankton and influence foraging behavior of amphibians.

Amphibians found in nearshore and wetland habitats also are particularly vulnerable to artificial lighting. Amphibians are highly sensitive to light and can perceive increases in illumination that are impossible for humans to detect (Hailman and Jaeger 1976). A rapid increase in illumination causes a temporary reduction in visual acuity, from which the recovery time may be minutes to hours (Buchanan 1993, Buchanan 2006). In this manner, a simple flash of headlights can arrest activity of a frog for hours (Perry et al. 2008). Amphibians are also sensitive to changes in ambient illumination from sky glow. Frogs in an experimental enclosure ceased mating activity during night football games when lights from a nearby stadium increased sky glow (Buchanan 2006). In an experiment to

investigate the effects of intermittent artificial light, male green frogs called less and moved more when exposed to the light of a handheld flashlight (Baker and Richardson 2006).

In naturally lit environments, some amphibians will forage only at extremely low light levels, and foraging times are partitioned among species with different lighting level preferences (Jaeger and Hailman 1976). The squirrel tree frog (*Hyla squirrela*) orients and forages at lighting levels as low as 10^{-6} lux and stops foraging at illumination above 10^{-3} lux (Buchanan 1998). The western toad (*Bufo boreas*) forages only at illuminations between 10^{-1} and 10^{-5} lux, while the tailed frog (*Ascaphus truei*) forages only during the darkest part of the night below 10^{-5} lux (Hailman 1984).

Laboratory experiments indicate that the development of amphibians is influenced by artificial light (Wise and Buchanan 2006, Wise 2007). Light interferes with the production of the hormone melatonin, which is involved in regulating many important functions, including sexual development, thermoregulation, adaptation of eyes to the dark, and skin coloration (Wise and Buchanan 2006, Wise 2007). Current research shows that artificial lighting slows larval amphibian development in the laboratory (**Figure 8**). The influence of artificial lighting on such physiological processes in the field is currently not well known, but the potential for lighting to harm amphibians and other wetland species is evident.

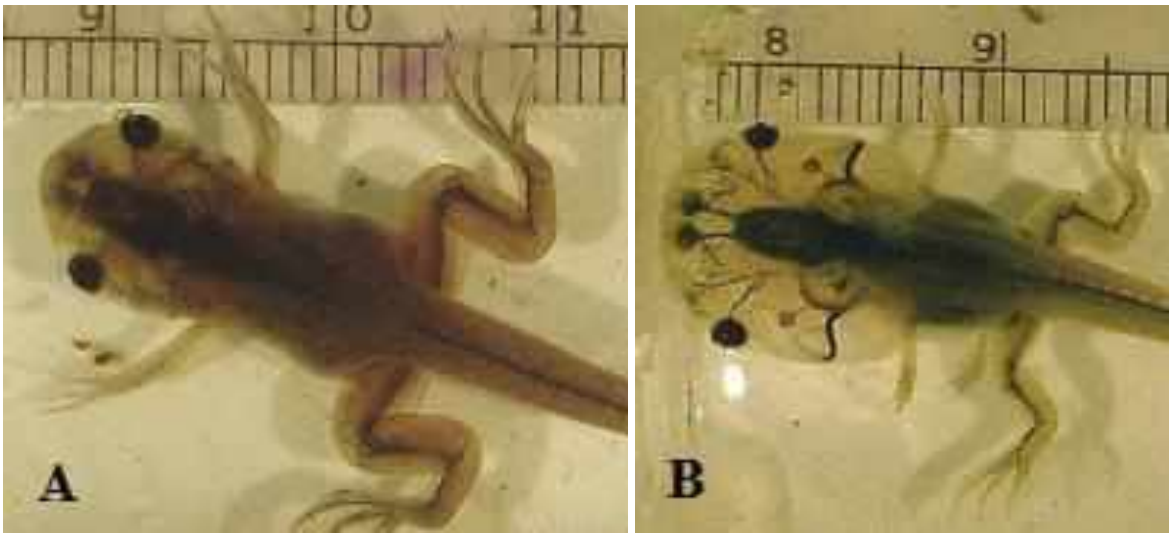

Figure 8. Two tadpoles of the same age and kept in 12:12 L:D lighting. (A) was kept in the equivalent of very dark night (10^{-4} lux) in the dark phase, while (B) was exposed to artificially bright illumination in the dark phase and is not yet metamorphosing (reprinted from Wise 2007).

Fishes are also highly attuned to natural ambient light conditions, with lighting levels influencing the distribution of predaceous species and the foraging behavior of their prey (Nightingale et al. 2006, Becker et al. 2013). Laboratory experiments have shown that the timing of downstream migration of salmon (*Salmo salar*) fry is significantly delayed and disrupted by lights of a similar illumination and spectrum as streetlights (Riley et al. 2013). Nocturnal downstream drift of insects is also delayed by artificial lighting (Henn et al. 2014).

Islands, oceans, and reefs

Light propagates unimpeded across open water, and its reach is extended beyond the curvature of the Earth by reflection off high clouds. Fog can increase local impacts of bright lights. Although light shining directly down on water tends to penetrate rather than reflect, light coming in at an angle is reflected. This physical property of water exacerbates the effects of coastal lighting as it is reflected and propagates out from the shoreline. Island, ocean, and reef environments are affected by artificial light sources that range from light-assisted fishing to urban sky glow to offshore hydrocarbon facilities (Davies et al. 2014) (**Figure 9**).

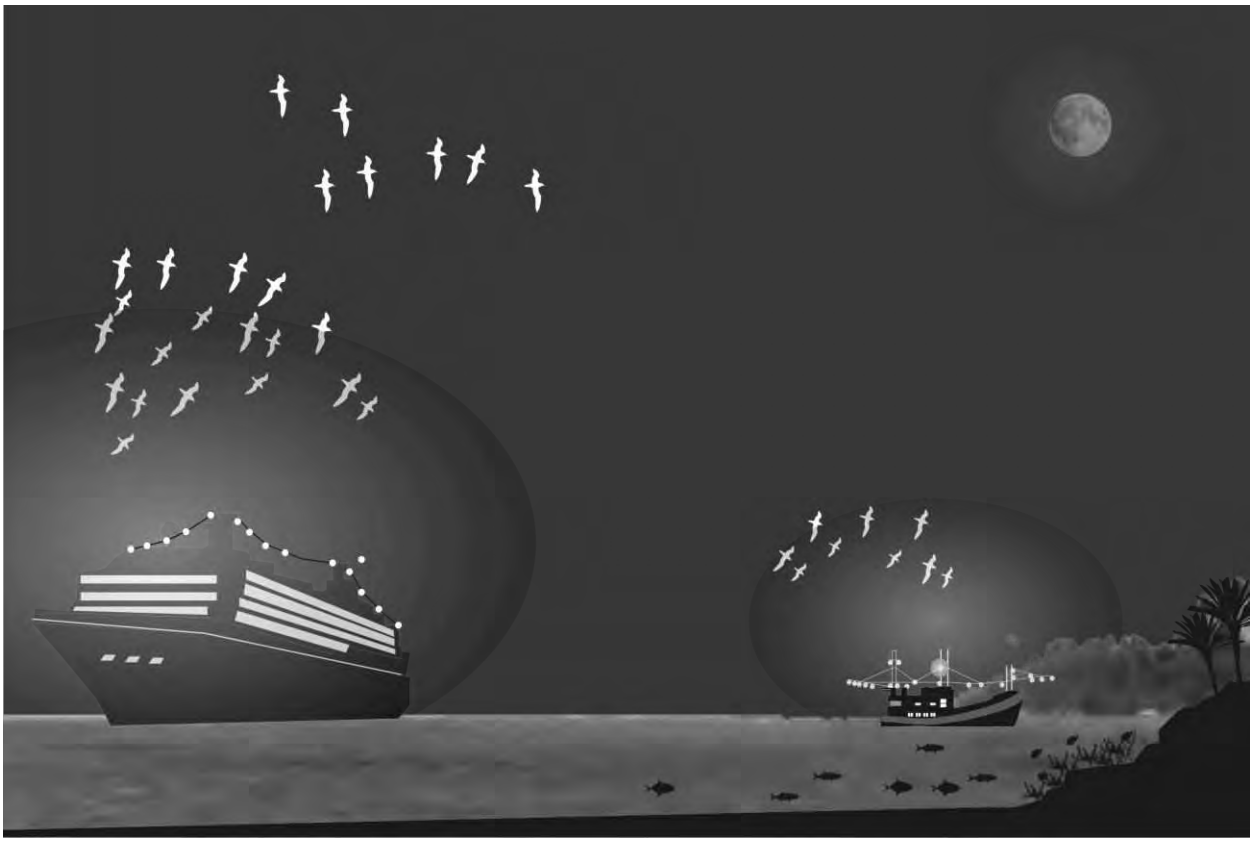

Figure 9. Cruise ships and squid boats are just two of the sources of artificial lighting on the oceans that attract seabirds and migrating songbirds.

In 1999, Xantus's murrelets (*Synthliboramphus hypoleucus*) nesting on Santa Barbara Island, part of Channel Islands National Park off the coast of southern California, were dying at twice the average annual rate. Park managers suspected this increase in mortality was directly related to a recent increase in fishing boats equipped with dusk-to-dawn floodlights to attract squid. Squid boats typically have 30,000 watts of light per boat. The number of squid boats increased dramatically in the 1990s, and in 1999 intense squid fishing occurred during murrelet nesting season (spring, while historically fishing was during fall and winter), and near important murrelet breeding islands. Managers believed that the nesting seabirds, without the safety of darkness, were subject to increased predation, especially from barn owls (*Tyto alba*). During the 1999 season, an unprecedented 165

dead Xantus's murrelets were found on Santa Barbara Island. Most of the dead were killed by barn owls, while five were victims of western gulls (*Larus occidentalis*). Researchers also recorded high nest abandonment closest to the most intensive squid boat activity. Faced with these observations, managers closed the areas around the islands to squid fishing, and death rates for the birds returned to normal. The excluded areas were subsequently incorporated into a permanent marine preserve with no fishing allowed to allow for replenishment of fish stocks. Also, the California Fish and Game Commission listed Xantus's murrelet under the California Endangered Species Act, citing artificial night lighting as one of the major threats to the species.

Nearly all seabirds are nocturnal, and an adverse response to decidedly unnatural conditions such as those suffered by Xantus's murrelets should not be surprising (Montevecchi 2006). Years of studies have shown that nocturnal seabirds are less active during moonlit nights, and those that are active suffer more predation during those times. Seabird chicks are directly affected by lighting levels; they are far less likely to be fed by adults during bright nights (Riou and Hamer 2008). Seabirds are attracted to lights perhaps because they naturally cue in on bioluminescent plankton to find prey (Montevecchi 2006). They have, therefore, long suffered from collisions with light sources on and adjacent to the ocean, including lighthouses, cruise ships, fishing vessels, lighted buoys, oil derricks, and streetlights on and near islands where they nest (Rodríguez and Rodríguez 2009, Rodrigues et al. 2012, Wilhelm et al. 2013); many of these collisions are fatal. Where lights correspond with critical habitat or high-use zones such as feeding or breeding areas, or migratory routes, the effects could be significant.

Other sources of artificial night lighting threaten the nighttime environment of the oceans. Cruise ships are pervasive, large, and are often brightly illuminated. Ships in the path of bird migrations, or near undersea food sources, may attract both migratory birds and foraging seabirds, which collide with the ships and can be stunned or killed. Anecdotal accounts have emerged where cruise ship staff frantically work to clear the decks of dead birds before passengers awake in the morning. Offshore hydrocarbon extraction platforms are also significant sources of light, and attract and kill birds through collision, exhaustion, and even by incineration in flares burning off natural gas. Many of these birds are long-distance migrants, and the losses at oil platforms may affect regional and global breeding populations.

Coral reefs are also threatened by artificial night lighting. Lighting has been used as a proxy for other impacts (urban development, intense fishing, hydrocarbon extraction) to assess risk to coral reefs on a global scale (Aubrecht et al. 2008). Aubrecht et al. (2008) also illustrated how artificial lighting would adversely impact reefs directly. Corals themselves are highly sensitive to light and synchronize spawning according to lunar cycles (Jokiel et al. 1985, Gorbunov and Falkowski 2002). Many coral reef species exhibit marked light-driven diel cycles or synchronize reproduction by monthly cycles (Sebens and DeRiemer 1977, Bentley et al. 2001, Levy et al. 2001). Predator–prey interactions are influenced by light levels, with diel vertical migration of both zooplankton (Yahel et al. 2005) and planktivorous fishes observed (Leis 1986). Natural light signals, such as bioluminescence, are important to marine organisms (Johnsen 2012), and can both attract and repel fishes (Holzman and Genin 2003, 2005). Artificial lighting at similar and greater intensity must

affect a range of marine organisms. Experimental investigation has now confirmed that lighting affects the colonization of marine invertebrates on surfaces (Davies et al. 2015).

Grasslands

Like other open habitats, light has few barriers in grasslands (**Figure 10**). Lights can thereby influence both illumination and direct glare over hundreds of meters or more, depending on topography. Artificial night lighting can be expected to influence habitat use and behavior of grassland species.

Figure 10. Grasslands are vulnerable to disruption from even distant lights because of their open character. Fireflies, often found in wet grasslands, can have their signals disrupted or be excluded by high illumination, while some grassland bird species, such as black-tailed godwit (*Limosa limosa*), have been shown to avoid streetlights in selecting nest sites (De Molenaar et al. 2006).

The lights of a road bisecting wet grassland in the Netherlands were shown to influence the spatial distribution of black-tailed godwit (*Limosa limosa*), a rare ground-nesting bird (De Molenaar et al. 2000, De Molenaar et al. 2006). When road lights were turned on during a breeding season, the birds nested slightly farther away from the road, with the effect extending 300 m (984 ft) from the lights. Birds that arrived first to the breeding area nested farther from the lights while those arriving later nested closer (De Molenaar et al. 2000, De Molenaar et al. 2006). The same research group investigated the behavior of mammals in wet grasslands and showed that some species (polecat, *Mustela putorius*, stout, *Mustela erminea*, weasel, *Mustela nivalis*, and fox, *Vulpes vulpes*) were

more likely to take paths near lights, while other species were not influenced or preferred darker areas (De Molenaar et al. 2003). Such differences in habitat use have the potential to change predation rates and distribution of prey species as well (Lima 1998).

Fireflies are another group of grassland species that can be adversely affected by artificial night lighting (Lloyd 2006). Because light is used for firefly communication, both for sexual behavior and in some interspecific interactions (where females attract males of other species to capture and eat them), any disruption of the ability to see light will have adverse effects. Artificial light washes out the signals used for communication and is potentially contributing to the decline of fireflies and other organisms that rely on bioluminescent communication (Lloyd 2006, Hagen and Viviani 2009, Bird and Parker 2014).

Deciduous and evergreen forests

Although the structural complexity of forests blocks light and reduces its propagation, species that inhabit the forest floor are sensitive to illumination at levels appropriate to the darker nighttime environment there (**Figure 11**). A review of the research on forest species shows some general patterns that illustrate the potential for lights to affect wildlife behavior.

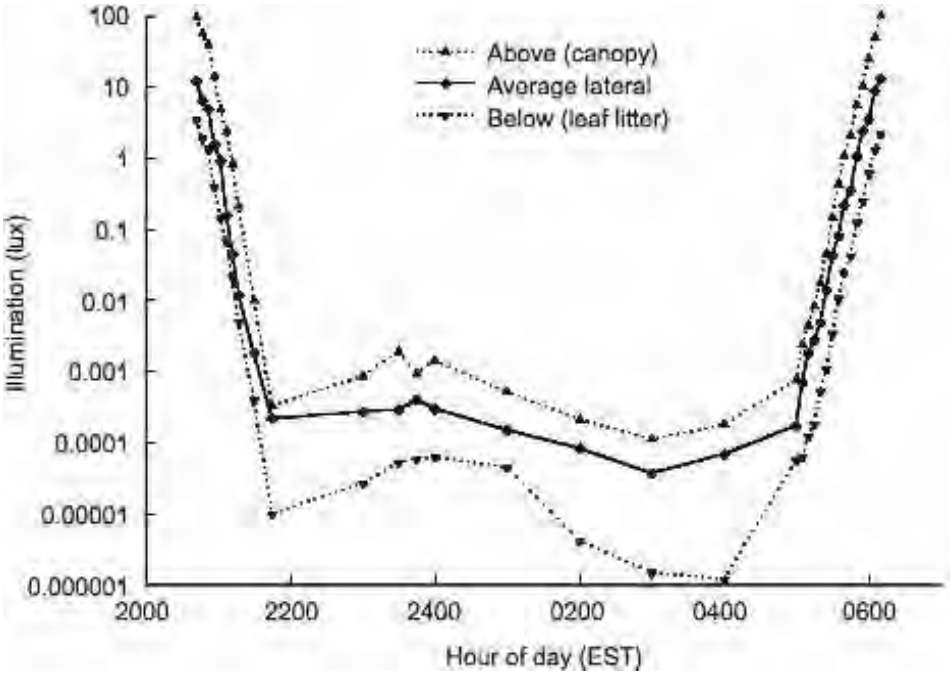

Figure 11. Illumination in deciduous forest (Buchanan 2006). Reprinted with permission.

As in many other ecosystems, salamanders in forests exhibit reactions to light equivalent to moonlight, under which foraging is reduced or delayed (Wise 2007) (**Figure 12**). This has been shown experimentally with dim artificial lights installed in a forest environment (Wise 2007). In two different experiments, lighting delayed the emergence time of nocturnal mammals (DeCoursey 1986, Barber-Meyer 2007) and reduced foraging activity (Barber-Meyer 2007). For sugar gliders, a

nocturnal forest mammal native to Australia, light equivalent to that produced by streetlights (7–12 lux) reduced the time individuals were active at night (Barber-Meyer 2007).

Figure 12. Species of the deciduous forest are adapted to the lower light levels found under the canopy. Flying squirrels and salamanders will delay their foraging under artificial lights.

In other instances, reproductive behavior can be affected by artificial lighting. The leafcutter ant *Atta texana* usually undertakes nuptial flights approximately 15 minutes before dawn, but in instances where security lights from homes and businesses were visible, the colonies flew 15 minutes after dawn (Moser et al. 2004). This change in timing interferes with behaviors that are carefully synchronized across colonies. Furthermore, artificial lights are also attractive to the flying ants and, as a result, may both decrease mating success and increase predation at the lights (Moser et al. 2004).

Alpine and tundra habitats

Alpine and tundra habitats are disproportionately represented in parks and other protected lands. They are on average less developed than other habitat types but can be, and are, developed for recreational and industrial infrastructure. Control of artificial lighting in alpine and tundra habitats is important to avoid disruptions of predator–prey interactions and to avoid disrupting annual rhythms that are entrained by day length.

The topography of mountainous habitats also makes them vulnerable to sky glow from distant sources (**Figure 13**). Because sky glow brightens horizons, areas of steep slopes are positioned to be

exposed to that light. In these locations, the aspect of the slope becomes important. Those facing bright horizons will be substantially brighter than nearby locations facing a different direction and therefore will be exposed to far less artificial lighting.

As in other habitats, predator–prey interactions in alpine environments are mediated by illumination (**Figure 14**). For example, small mammals of rocky outcrops typical of alpine regions are often nocturnal, foraging in open areas at night and retreating to the safety of outcrops for shelter (Kramer and Birney 2001). In experimental conditions one such species, long-eared mouse (*Phyllotis xanthopygus*), foraged less under 1.5 and 3.0 lux treatments (up to very bright moonlight) when compared with a 0.0 lux control (Kramer and Birney 2001). Similar results have been found for snowshoe hares (Gilbert and Boutin 1991), which are subject to more predation under brighter nocturnal conditions, especially during the winter (Griffin et al. 2005). Such small mammals depend on natural darkness for foraging to keep up body weight (Vasquez 1994).

Figure 13. Alpine habitats can be affected by distant lights and those from recreational and industrial facilities.

Circannual rhythms are found in most animals, but the environmental conditions that influence them are less well understood because of the long period necessary to conduct experimental research (Beier 2006). Light appears to have a large influence in setting these cycles, although temperature is also important (Beier 2006). Light can be important in determining when species react to the seasons (e.g., hibernation, Hock 1955), and consequently disrupting these signals has the potential to put

species out of phase with climate. In alpine and tundra environments, where conditions change so dramatically between the seasons, appropriate synchronization of activities is important. For example, reindeer (*Rangifer tarandus*) eyes change seasonally to reflect different wavelengths of light; color of the tapetum lucidum shifts from yellow in the summer to blue in the winter, which is associated with increased retinal sensitivity during the dark winter nights (Stokkan et al. 2013). Captive reindeer exposed to sodium vapor streetlights, not directly visible but just over the horizon, are reported to have green eyes in the winter, not completing the normal transition from yellow to blue, and with reduced visual sensitivity (Yong 2013).

Figure 14. Predator–prey interactions are affected by artificial lights during long nights on the tundra.

Urban environments

Even though urban environments have many sources of artificial lighting at night, variations within already light-polluted environments still make a difference to wildlife (**Figure 15**). For example, American crows (*Corvus brachyrhynchos*) choose roost sites in urban areas that are on average more brightly illuminated than non-roost sites (Gorenzel and Salmon 1995). Presumably, this allows the communal predator response behaviors of the flock to operate more efficiently, reducing predation from owls. Elevated populations of this native species have adverse consequences for other native species for which the crows are predators. In another example, urban-tolerant bat species are influenced by the degree of illumination on the exit hole of their roosts. Nightly emergence is delayed by illumination of the exit hole, which reduces fitness of individuals in the colony and can eliminate the colony altogether (Boldogh et al. 2007). Because of the importance of bats as

consumers of insects, and their conservation status, the adverse impacts of lighting are concerning (Stone et al. 2015).

Figure 15. Cities are affected by altered light environments, which are exploited by synanthropic species such as crows and some bat species.

Cities are also sites of mortality for nocturnally migrating birds, which are attracted to lights. Birds die either in collisions with buildings at night, or during the day when they attempt to regain their orientation and continue migration. This phenomenon is well documented in Chicago, Toronto, New York, and Washington, D.C. A notable example in a national park is the ongoing mortality of nocturnal migrant birds at the Washington Monument, which started when it was illuminated (Overing 1938).

The profusion of light in urban areas also has spillover effects on surrounding natural areas and open spaces within cities. For example, extremely high levels of ambient light are measured in the Santa Monica Mountains National Recreation Area near Los Angeles, with all-sky brightness exceeding natural levels by 18.4 times and maximum nocturnal vertical illuminance 32.4 times brighter than natural levels (J. White and C. Moore, pers. comm.). Although it is difficult to address the multitude of sources of light, it is worthwhile for parks to incorporate lighting and the night sky as part of their education, outreach, and engagement in communities adjacent to and near parks (Aubé and Roby 2014).

The evidence from across habitat types indicates that artificial lighting at night is either proven to, or has the potential to, disrupt the natural behavior of wildlife species, sometimes with lethal consequences. From this context we can identify practices that can reduce and minimize the effects of lighting in parks and other lands managed for natural resource values.

Mitigating the Effects of Lighting on Protected Lands

Knowledge about the effects of lighting on wildlife continues to grow. All indications are that lighting can have cumulative and additive consequences that are especially important for vulnerable species. Many general approaches to minimizing the effects of artificial lighting on wildlife are known. To reduce effects on certain target species, these mitigations may need to be adapted to craft desirable solutions for specific locations. In the following two sections, considerations for developing such mitigation measures are discussed. First we introduce the attributes of nighttime lighting that might be manipulated — spectrum, intensity, direction, and duration — and how different groups of species might be affected by them. Then we review the many contexts in which light is used (e.g., security lighting, vanity lighting, communication towers) and identify preferred mitigation strategies for them.

Approaches to minimize lighting impacts

The impacts of artificial lighting to wildlife can be reduced in five ways: 1) avoiding use of lighting that is not needed, 2) controlling color spectrum, 3) limiting light intensity, 4) managing the direction of light emissions, and 5) limiting the duration of light output. For some of these characteristics, a single approach applies in all instances. For others, the recommendation depends upon the context of use or the species that might be affected. A combination of mitigation approaches is likely to be more effective (e.g., reducing intensity and adjusting color spectrum) than would be any approach taken individually.

Need

The first question that should be asked about artificial lighting, especially in natural areas, is whether it is in fact needed. In some situations, a creative solution, such as the choice of a pale color for a pathway, curb, or steps, is all that is needed to guide visitors (**Figure 16**). In others, lighting can be left to the visitor to provide in the form of headlights or a flashlight. Only when the need is demonstrated and necessary for visitor experience, safety, or security, should lights be installed.

Figure 16. A pale-colored path can be just as effective as electric lights in some park situations.

Spectrum

It is tempting to believe that a certain spectrum of light will minimize the effects of lighting in all situations. Unfortunately, no universal solution exists. Rather, it is possible to identify spectra of light that have shown to affect wildlife less in certain contexts. The only 100% wildlife-friendly light is one that is switched off or never installed.

The higher efficiency of high-pressure and low-pressure sodium lamps resulted in their widespread adoption in street lighting applications and security lighting, replacing the older mercury vapor lamp technology. Recently, however, full-spectrum light sources such as metal halide lamps, compact fluorescent lamps, and LEDs are becoming more common (Gaston 2013). Full-spectrum lights appear white, in contrast with other lights such as sodium vapor lamps that appear yellow or orange. Earlier technologies, such as mercury vapor lamps, were also full-spectrum, but have largely been replaced by sodium vapor lamps. LEDs are more efficient than older lamps used for outdoor lighting, and have greater color rendition than sodium vapor light sources. This return to white light sources brings certain advantages for human use, but includes a wider range of wavelengths, potentially impacting more species (Stone et al. 2012) and exacerbating sky glow (Aubé et al. 2013).

The combination of colors that make up a full-spectrum light is described by the correlated color temperature (CCT) of the light. CCT is measured in degrees Kelvin and corresponds to the appearance of light that would be emitted from an idealized “black body” if it were heated to that temperature. Lower CCTs are dominated by yellow and other longer wavelengths, while higher

CCTs are dominated by blue and other shorter wavelengths. For example, an incandescent bulb has a CCT of 2600–2700 K (Elvidge et al. 2010), while a metal halide lamp has a CCT of 2900–4200 K (Elvidge et al. 2010) and direct sunlight 3000–30,000 K, but usually 5200–6000 K (Thorington 1985). Full-spectrum LEDs are offered in many color temperatures, from 6500 K to 2700 K. High-pressure sodium lamps have a CCT of around 2100 K (Elvidge et al. 2010) and low-pressure sodium lamps, which are almost monochromatic yellow, are measured at 1740–1800 K (Thorington 1985, Elvidge et al. 2010).

One general rule is to avoid any light that has emissions in the ultraviolet spectrum and adjacent short wavelengths. Ultraviolet light is not visible to humans, yet is visible to other species. Insects are highly attracted to ultraviolet light and their attraction and mass death at lights would be dramatically reduced by eliminating ultraviolet light from general use (Frank 1988, Eisenbeis and Hassel 2000, Eisenbeis 2006, Frank 2006). Mercury vapor lamps are high in ultraviolet radiation, while other commonly used outdoor lamps (e.g., metal halide, fluorescent) have some ultraviolet as well. LEDs have no ultraviolet emissions and therefore attract fewer insects than lamps of comparable intensity and color temperature that do have some ultraviolet emissions (Poiani et al. 2015, Longcore et al. 2015).

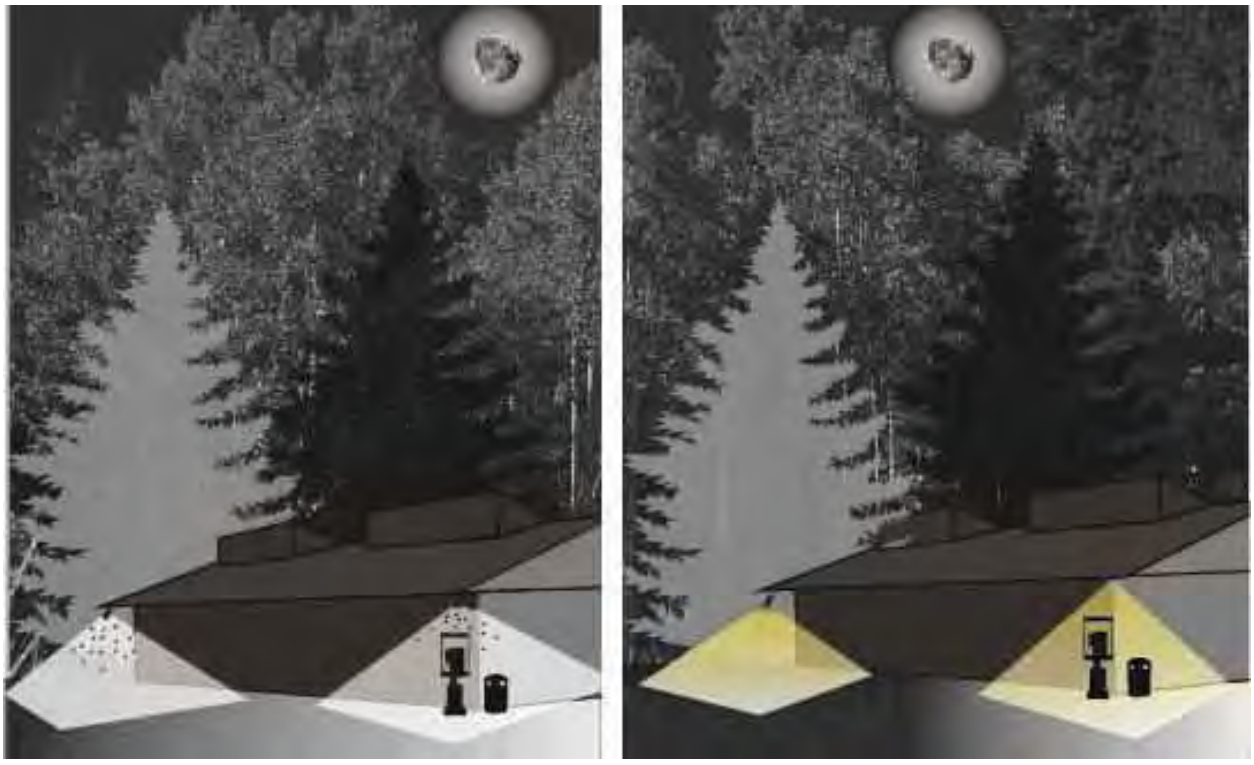

Figure 17. Yellow light that does not contain blue or ultraviolet wavelengths attracts far fewer insects.

Insects are also attracted to light in the short visible wavelengths (e.g., violet and blue) (**Figure 17**). Full-spectrum lighting that allows good color rendering for human vision is not advisable from the standpoint of ecological effects because it contains light in the blue spectrum (Eisenbeis and Eick

2011). All lights heavy in the blue portion of the spectrum, such as fluorescent lights, metal halide lights, and full-spectrum LED lights, will have greater impacts on insects than lights with longer wavelengths (e.g., low-pressure sodium vapor lamps or yellow/amber LEDs) (Eisenbeis and Eick 2011, Pawson and Bader 2014, Poiani et al. 2015, Longcore et al. 2015). If full-spectrum lighting is required, then the lowest possible color temperature is recommended (Longcore et al. 2015).

Blue light contains the most biologically active wavelengths for physiological processes such as the production of hormones and the timing of daily activities (Beier 2006, Brainard et al. 2015). This concern has been best expressed relative to human health (Pauley 2004, Brainard et al. 2015), but blue light also disrupts circadian rhythms in wildlife. To minimize disruption to circadian rhythms, shorter wavelengths such as blue and violet should be avoided. They might also be avoided to minimize influence on species that are phototactic to blue light, such as many frog species that have a blue light preference whereby they move toward blue light, presumably as an escape mechanism that leads them away from vegetation (and into water) in times of danger (Hailman and Jaeger 1974, Buchanan 2006); these preferences can vary depending on the intensity of illumination, however (Buchanan 2006).

Figure 18. Green lighting designed to minimize attraction of birds developed by Philips. Shell is using these lights on an oil platform in Alaska and Philips is adding the lights to its regular catalog. Photograph courtesy of Joop Marquenie.

Birds are able to orient to the Earth's magnetic field under monochromatic blue or green light, but such navigational ability apparently does not function under lights that are only red or yellow. The molecular mechanism that allows detection of the Earth's magnetic field requires light of a certain wavelength to be activated (Ritz et al. 2009), which presumably explains the inability of migratory birds to orient under light that lacks those wavelengths (Wiltschko et al. 1993, Wiltschko and Wiltschko 1995). Dutch researchers have experimented with the use of specially designed lamps that contain blue and green light at coastal locations and on offshore platforms to see if the number of

attracted and disoriented birds is decreased (van de Laar 2007, Poot et al. 2008). Results show blue and green lights influence birds less than red and full-spectrum (white) light, although the effects on other species have not been documented in the scientific literature (**Figure 18**; **Figure 19**).

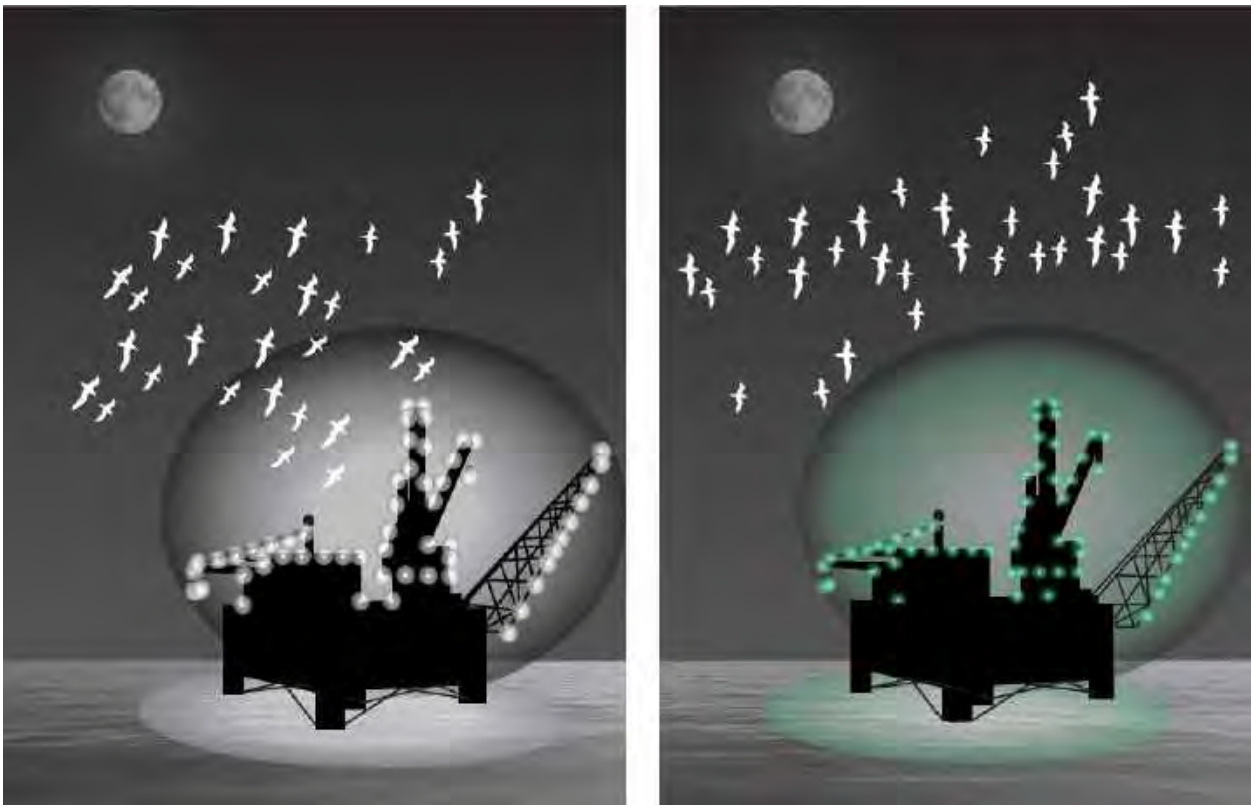

Figure 19. Green lights have been investigated for use on offshore structures and shown to be less attractive to birds.

In other situations, light that includes longer wavelengths appears to attract few insects and does not disrupt orientation of sea turtle hatchlings. For this reason, yellow lights are commonly identified as being wildlife-friendly (**Figure 17**). These same lights, however, reduce the foraging activity of native beach mice (some species of which are endangered) along the Florida coastlines where turtle-friendly lighting is recommended (Bird et al. 2004). Fireflies are vulnerable to impacts from yellow light because it is this part of the spectrum that is used by those species flying after dusk (Lloyd 2006).

Red light appears to disrupt the orientation capabilities of birds, but it seems to have the least effect on other species (**Figure 20**). Few insects are attracted to red light and dark-adapted eyes are not bleached by red light, making it the spectrum of choice for stargazers. In low-light environments in parks, red light might be preferable where lights are needed for safety reasons (**Figure 21**).

Figure 20. Red light does not disrupt dark-adapted vision and is therefore appropriate for campsites and locations used for astronomical observation.

Figure 21. Illumination of a stairway at a campground by two low-intensity red bulbs instead of by a bright white spotlight (Wagner et al. undated).

Through all the considerations for different taxa, a few general lessons emerge to guide use of spectrum: 1) the choice of color significantly affects the degree of biological disruption; 2) narrow-spectrum lights are preferable to broad-spectrum sources (i.e., white light); 3) ultraviolet light should be avoided; 4) blue and shorter wavelengths increase biological responses and generally should be avoided; and 5) concerns about individual species in an area may influence the choice of least disruptive color for lights.

Intensity

Land and facility managers have great latitude in selecting the intensity and quantity of lighting used. From a wildlife perspective, discretion should be exercised to use the minimum amount of light required. This can be accomplished by significantly decreasing the luminous output commonly specified by lighting designers. Land managers should not rely on standards promulgated by professional societies to guide lighting levels for natural areas because these are generally developed for urban/suburban areas with little to no regard for wildlife. Rather, every effort should be made to reduce the intensity of lights and still achieve the desired function.

Reduction in lighting intensity benefits species in the vicinity of lighting and also reduces the reflection of light in the atmosphere. The glow of lighted areas can thereby be reduced, decreasing impacts to natural systems and park visitor experience in wildlands. Often, illumination levels can be reduced without adverse consequence for human activity. In fact, reducing the contrast between light and dark areas increases the ability of humans to see. The human eye adapts to the brightest light in view. As the eye adapts to bright lights, acuity in darker areas is lost. Bright lights plunge the surrounding areas into dark shadows, while with dimmer lights the eye is able to retain some of its ability to see in darker areas.

Direction

Shielding lights is a common mitigation measure to reduce impacts to natural lands and species (**Figure 22**). Usually this involves shielding a fixture so that little or no light is emitted above the horizontal plane, and less than 10% of the light is emitted within ten degrees below the horizontal plane. This is the definition of a full cutoff lighting fixture. Shielding in this manner greatly reduces (but does not eliminate) sky glow. Light still reflects off the ground and scatters, so reduction in intensity should be combined with shielding. Downward-directed lights may still have adverse ecological consequences such as attracting insects and species that feed on the insects (e.g., bats, frogs, birds), or directing light into sensitive habitats such as wetlands and rivers.

Land managers should endeavor to shield lights beyond full cutoff to ensure that light falls only on the intended surfaces. Such mitigation will minimize direct glare, which can affect the orientation of organisms across distances (Reed et al. 1985, Telfer et al. 1987, Beier 1995, Longcore and Rich 2004); this will also minimize the area that is artificially illuminated. Design solutions to achieve these goals include the use of embedded lights to illuminate important surfaces (**Figure 23**) and simple retrofits to shield existing lights (**Figure 24**).

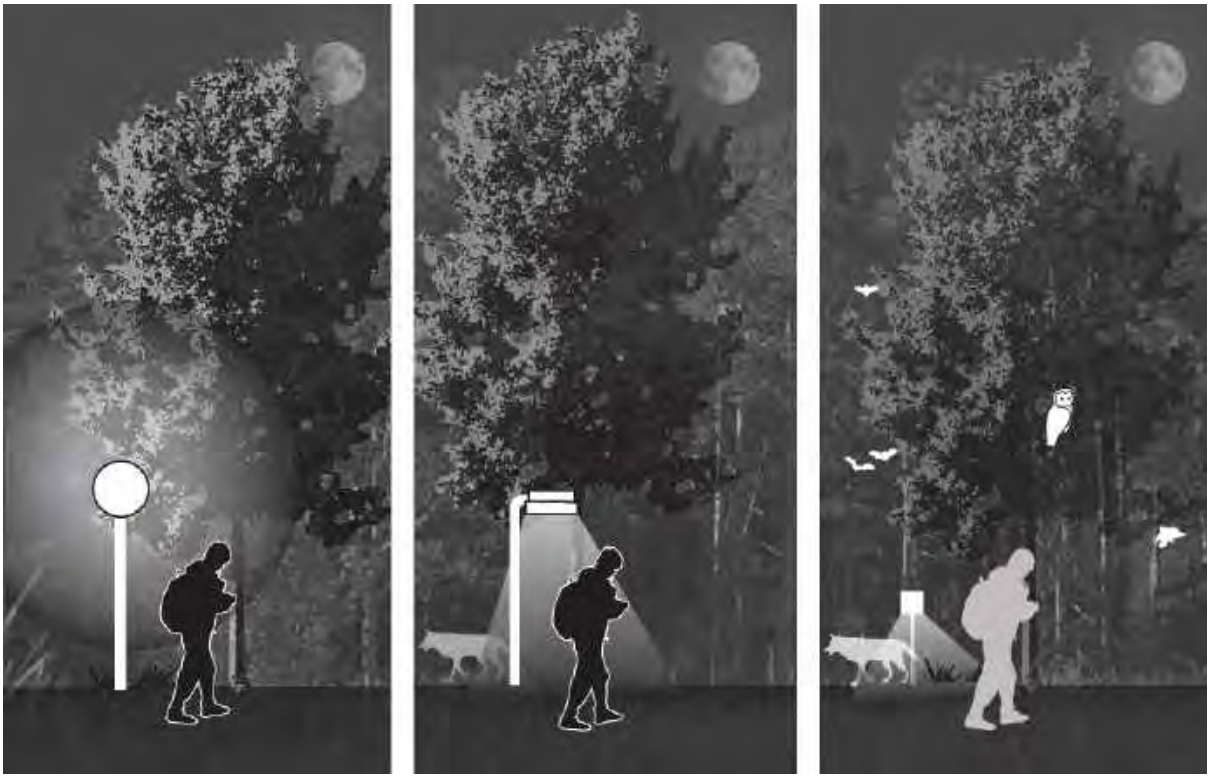

Figure 22. The more focused light can be on its target, the less it will affect other species.

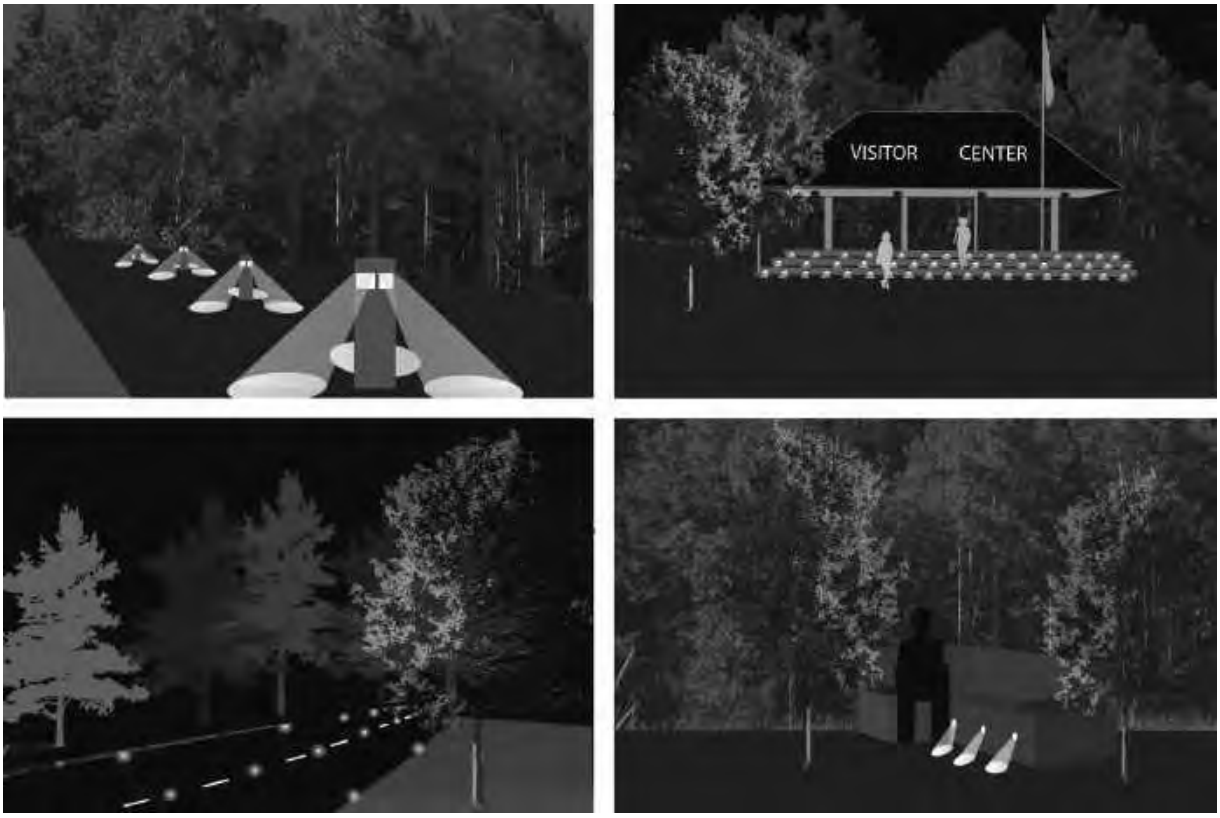

Figure 23. Embedded lights allow wayfinding with minimal intensity and good directional control.

Figure 24. A full cutoff shield being installed on an existing light on the lodge at Yellowstone National Park. This previously unshielded light was visible across the lake and from the backcountry. Photograph by Travis Longcore.

Duration

Impacts from lighting can be reduced by changing the duration of illumination. This approach reduces some impacts, but it may have some adverse consequences for those species sensitive to a changing light environment and so should be implemented with these limitations in mind. One common way to reduce the duration of illumination is to install a motion detector so that a light is only on when there is activity in a particular area (**Figure 25**). Although this limits the amount of time lights are on, lights that go on and off at irregular intervals may disrupt the nocturnal behavior of some species. For example, green frogs (*Rana clamitans*) reduce calling behavior and move away when a light is shining on them (Baker and Richardson 2006); return to a dark-adapted state can take hours (Buchanan 2006).

Another restriction on duration is setting a time for lights to be extinguished each night (**Figure 26**). For example, the lights that illuminate Mount Rushmore are only on for a few hours each night. This approach, known as part-night lighting, reduces impacts by allowing darkness during the late night and early morning hours. Depending on the timing of the lighting, darkness can be maintained for the majority of the activity period for a target species (Day et al. 2015). This approach, however, may still disrupt activities during the specific light conditions at dusk that are required by other species (Longcore et al. 2003, Day et al. 2015). Rather than a smooth range of illumination conditions occurring as the sun goes down and darkness falls, sites will experience a single illumination level until the lights are turned off. Many groups of species share resources across lighting levels; that is, one species may forage at dusk, another right after dusk, and another in the dark of night (Hailman 1984). Increased illumination, even on a temporary basis at dusk or dawn, reduces the time available

for critical behaviors and could eliminate them altogether if a species prefers the transitional lighting levels of dusk when lights are illuminated. If artificial lighting eliminates a significant period of potential activity time for a species, the long-term consequences will be negative. In studies of bats, part-night lighting has been found to be ineffective in avoiding the activity periods of most species in the locations studied (Azam et al. 2015, Day et al. 2015).

Figure 25. Motion- and heat-detecting lights provide illumination only when it is needed.

Figure 26. Timed lights may affect species negatively during the transitional period of dusk, but may reduce impacts later at night.

There may be instances where avoiding lighting during a particular time when animals are active is an appropriate way to mitigate impacts. Many species are active during the crepuscular periods of dusk and dawn. If lighting can be avoided until after dark, or closer to dark, certain impacts on those species might be avoided. Setting photodetectors to activate lights only at very low levels of illumination will avoid the biologically active crepuscular period, reduce insect attraction, and limit light to after civil twilight when it is really needed.

Whenever lights are required, reducing their intensity or turning them off during periods they are not needed should always reduce impacts. For example, the Dutch government has mitigated lighting impacts on sensitive wet grassland habitats by turning off roadway lighting at 11 P.M. and replacing it with 7-watt incandescent bulbs halfway up the light standards (De Molenaar et al. 2006). These lights allow for wayfinding and have not changed the number of accidents occurring on the road.

Lighting situations

In addition to controlling for spectrum, intensity, direction, and duration, mitigation measures can be devised for many other situations in which lighting might be installed in parks. In the sections that follow, we discuss the issues involved with mitigating impacts from a series of different situations that might be faced by a park manager.

Communication towers

Each tower in the United States that is taller than 200 ft (61 m) must have obstruction lighting in accordance with Federal Aviation Administration (FAA) guidelines. Lighting is a primary factor resulting in the attraction to and mortality of birds at towers. An estimated 6.8 million birds per year are killed at tall towers (Longcore et al. 2012), including many species of conservation concern (Longcore et al. 2013). Reviews of previous work, and subsequent studies, have shown that mortality can be reduced by using a lighting system that has flashing lights only, whether these are strobe lights or red flashing lights (Gehring and Kerlinger 2007). White strobe lights have long been approved as lighting on towers and the FAA has updated its regulations to allow red flashing lights only (see FAA Advisory Circular 70/7460-1K). It is also important that towers do not have ground-level lighting around them because these lights can attract birds that then collide with tower guy wires (Longcore et al. 2008). Another option for tower lighting is an audio-visual warning system like OCAS (http://www.ocasinc.com). This approach uses radar to detect nearby aircraft, activating marker lights and emitting a verbal warning on aviation band radio. It is essentially a motion detector for tower lighting.

Night hiking and mountain biking

Night hiking and mountain biking have become popular activities in natural areas. The lights used in these activities, especially those used in mountain biking, have become brighter in recent years. For example, full-spectrum LED lights that emit 3,600 lumens (approximately the same as a 200-watt incandescent bulb) are advertised for use by bikers. Activities such as these expose wildlife to unnatural disturbance at night; this affects behaviors both because of the disturbance itself and because of the potential bleaching of eye pigments ("blinding") from which recovery time can take minutes to hours.

Managers can mitigate the impacts of night hiking and biking by employing various strategies. These include:

1. Restrict the time of month when illuminated nocturnal recreation is allowed to the days before and after the full moon. In this manner animals are allowed the darkest part of the month as a refuge from disturbance.
2. Restrict the total luminous intensity of lights used in these activities.
3. Set curfews for illuminated nocturnal recreation.
4. Restrict nocturnal recreation activities to areas that are already disturbed by night lighting, leaving more remote wildland areas protected from nocturnal disturbance.

Campsite lighting

Although "traditional" camping with firelight and flashlights is certainly still a popular activity, more and brighter portable lights are being brought to campsites. Large arrays of lights are readily available and increasingly used by campers. Such lights can degrade the nighttime camping experience for other campers and will have greater impacts on wildlife than a campfire or small personal flashlight. Park managers might consider establishing guidelines for nighttime lighting at campsites, including limits on overall illumination, lighting curfews, and recommendations to use

flashlights instead of area lighting. Lighting restrictions could be established in conjunction with quiet hours, and address portable lanterns and recreational vehicle lights. In especially dark areas, managers could recommend the use of red filters on flashlights. Such actions should be paired with minimizing lighting from the existing infrastructure (e.g., converting lights on bathrooms to low-intensity red lamps).

Off-road vehicles

Deserts and beaches often accommodate vehicular recreation. Vehicles commonly have 1,000–1,500 lumens of forward-facing light, and because this is concentrated in a fairly narrow cone, the light intensity can be very high, with low-beam headlights exceeding 4,000 candela on axis (candela is a unit measuring the brightness of a light emitted in a particular direction). For wildlife along the axis of the headlight, the intensity of a directional headlight is equivalent to an unrestricted 100,000-lumen light source (Schoettle et al. 2004). This disruption can be an intermittent impact or, in some situations, a chronic one. For example, vehicles on a beach will often park with the headlights kept on, in which case multiple headlights will be directed into the shoreline environment and have the effect of a much larger number of streetlights due to their concentrated and directed nature. The most effective mitigation would be to prohibit vehicles from these environments during sensitive times for wildlife. Additional mitigations may include restricting headlights to when the vehicle is moving or requiring low beams only.

Monuments

Parks must consider the need to preserve natural and cultural resources when making decisions related to lighting cultural monuments. For example, the Washington Monument is bathed in white light and is known to attract and kill migratory birds (Overing 1938). Because the Washington Monument has been illuminated at night since the 1930s and is so powerfully symbolic of Washington, D.C., it is not feasible to propose elimination of lighting altogether. Limitation on the hours of illumination is probably the best management action in such situations. Lighting for monuments should be designed to illuminate the monument only, and with the lowest intensity possible. Bright lighting that might have been required to accommodate photography in the past is no longer needed with current digital imaging technology.

Lighting schemes at monuments could also play a role in pest management. At the Lincoln Memorial, the lights are turned on at twilight when midges and gnats fly over from the Potomac River and onto the Memorial. This in turn attracts many spiders that weave webs on the monument and require extensive and frequent cleaning (C. Moore, pers. comm.). It might be possible to turn the lights on slightly later, after the crepuscular period, or to change the spectrum of light used to eliminate short blue and ultraviolet wavelengths. In such a manner the lighting scheme then becomes part of an Integrated Pest Management program.

Light-assisted fishing

Offshore lighting poses threats both to aquatic and terrestrial ecosystems. Light has a long history of use as a method to attract fishes for capture. In artisanal fisheries, dim lamps may be used on small human-powered boats. Current industrial-scale fisheries, however, use extremely bright lights (equivalent to 30,000 watts incandescent) to attract squid and other fishes. Even boats that do not use

lights to attract their catch operate during the night and are highly illuminated. Illumination in this manner affects behavior of fishes (Nightingale et al. 2006) and other aquatic organisms (Forsythe et al. 2004). Lighting is also implicated in the mortality of seabirds in fisheries (Dick and Donaldson 1978, Carter et al. 2000). Spillover light on seabird nesting colonies has the potential to increase predation on vulnerable species (Keitt et al. 2004). Park managers should take action to reduce fishing activity with disruptive lighting near sensitive island habitats and in marine protected areas. A range of options is available to do so, including outright bans, limiting light-assisted fishing by phase of the moon (to dates around the full moon), and limiting total luminance allowed in protected waters.

Security lighting

Managers are often faced with pressure to install security lighting in hopes of decreasing illegal activity. The evidence that increased illumination reduces crime is unclear at best (Tien et al. 1977, Sherman et al. 1997), and dimming or shutting off lights may in fact reduce crime (Steinbach et al. 2015). Some schools use a "dark campus" approach, wherein all lights are extinguished at a certain hour. Lights seen after this time are then quickly recognized as indicative of unauthorized activity (Mizon 2012). Park managers should think very carefully about installation of any dusk-to-dawn security lighting. It has very little chance of being effective if staff members are not on site to observe activity. Complete darkness at night for areas in parks and protected areas that are off-limits and unoccupied should be considered in consultation with law enforcement.

Bridges

Bridges can introduce artificial lighting into natural areas through roadway lighting for safety or through architectural lighting. Both of these have the potential to disrupt natural habitats. For example, harbor seals used the lights on the Puntledge Bridge in British Columbia to form a "feeding line" and intercept outmigrating juvenile salmonid smolts (Yurk and Trites 2000). Extinguishing these lights led to a decrease in salmon mortality. Other studies document increased predation on fishes under illuminated bridges and docks (Nightingale et al. 2006). For bridges with tall structures, illumination of these towers may result in attraction of migratory birds. Such lighting should be avoided to the extent possible, such that obstruction lighting is limited to red flashing lights (if lighting is required by the FAA) and any roadway lighting is carefully directed onto the roadway with little or no spillover into the river. Furthermore, use of yellow light is preferable under most circumstances to minimize the attraction of insects, although selection of yellow lights alone will not eliminate the effects of lighting on foraging behavior of mammals (Bird et al. 2004). Other considerations with bridges include the synergistic effects of lighting and polarization that misleads insects and may even result in bridges being dispersal barriers along rivers (Horváth et al. 2009, Málnás et al. 2011).

Roadway lighting

Roadway lighting is a major source of outdoor illumination and contributes significantly to sky glow. In a study of lighting in Tucson, Arizona, roadway lighting accounted for 12% of upward directed lighting, following only commercial lights (36%) and sports fields (32%) as a proportion of total uplight (Luginbuhl et al. 2009). To maintain natural illumination conditions inside parks, managers must work with communities outside park boundaries to address these sources. Inside park

boundaries, managers must make the decision whether roadway lighting is necessary in the first place, and if so, what characteristics it should have. To minimize impacts on wildlife, roadway lighting should be avoided to the extent possible, and where used should only be designed for the required intensity. The recommended lighting for a local road with low pedestrian conflict in the United States is 3–4 lux (ANSI/IES RP-8-14), which is more than 30 times brighter than the full moon's maximum intensity, so no roadway lighting is ecologically trivial. Recommended illumination for most roadways ranges from 6–15 lux (ANSI/IES RP-8-14).

One issue with reducing illumination for roadways is a concern that any reduction will increase traffic collisions. Studies of changes to roadway lighting in England and Wales, however, found no significant effect on number of traffic collisions from part-night lighting, switching off roadway lighting entirely, or changing the spectrum of roadway lighting (Steinbach et al. 2015).

Where light is essential, fixtures should be full cutoff and shielded to minimize glare from any non-road site, especially in areas with known sensitive species. The best overall choice for spectrum is probably yellow (e.g., low-pressure sodium or yellow/amber LED), but technical considerations may lead to use of a broader spectrum (e.g., high-pressure sodium). Yellow/amber LED streetlight fixtures are commercially available in response to demand for lighting with minimal impacts on bats (e.g., Innolumis bat lamp from the Netherlands) and other wildlife (e.g., Star Friendly® lights, C&W Energy Solutions).

Other alternatives are available to further reduce the impacts of street lighting. Embedded roadway lighting (**Figure 27**) has been investigated in Florida as a way to minimize impacts on nesting sea turtles (Bertolotti and Salmon 2005). Such lights may be useful in locations where snow plowing is not necessary. Another alternative is the use of dynamic lighting systems that decrease illumination based on the time of day or traffic volume so that lights are extinguished by a certain time at night or at a percentage of peak traffic (Collins et al. 2002).

Interested park managers can consult reviews on the impacts of light from street lighting systems, which recommend against full-spectrum lamps because of ecological, physiological, and dark-sky impacts (Falchi et al. 2011, Bierman 2012).

Vehicles along roads can cause the type of periodic changes in lighting levels that can affect animal behavior (Baker and Richardson 2006) and influence views of the night sky (Luginbuhl et al. 2009). Birds, especially migratory species and seabirds, can be attracted to vehicle headlights (Gauthreaux and Belser 2006). Although additional research on this topic would be welcome, managers can mitigate impacts from headlights by providing shielding of sensitive receptors using a range of physical barriers, including berms, dense shrubs, or even walls in particularly sensitive areas.

Figure 27. Embedded roadway lighting. These LED lights installed in the pavement are not visible to sea turtles nesting on the adjacent beach and are well received by motorists and pedestrians (Bertolotti and Salmon 2005). Photograph courtesy of Michael Salmon.

Energy production installations

Efforts to increase domestic energy production have resulted in pressure to explore and extract fossil fuels and develop industrial-scale facilities for wind and solar energy both on land and water. Energy production facilities have the potential to affect natural resources on park properties that may be found intermixed with other public and private lands approved for such activities. The direct impacts of such activities are of great conservation concern, but are not discussed here. In the event that such facilities are evaluated in the environmental review process, the following recommendations could be made to minimize the impacts of artificial night lighting.

Wind energy installations are generally illuminated with red flashing lights at the corners of arrays of turbines. Not all turbines have obstruction lighting. Researchers documenting mortality of animals (both bats and birds) at wind turbines have concluded that these flashing lights do not attract birds, but that constant illumination of ancillary structures on the ground is associated with increased bird mortality at nearby turbines (Kerlinger 2004, Kerlinger et al. 2010). Wind turbines currently are estimated to kill on the order of 100,000 (Kerlinger et al. 2011) and 573,000 (Smallwood 2013) birds per year, with this number likely to grow 30-fold in the next 20 years to meet federal goals for renewable energy. Ensuring that lighting is only red flashing with no steady-burning lights on any accessory structures would reduce mortality of nocturnal migrant birds, but would not mitigate the significant bat mortality that is associated with wind turbines (Kunz et al. 2007, Smallwood 2013).

Solar power plants are proposed and being built in open desert areas near parks and protected natural lands. Such facilities should not require dusk-to-dawn night lighting. If security lighting is desired, the recommendation should be made that it be fully shielded, low intensity, and on a motion detector.

Oil and natural gas facilities are often brightly illuminated at night. This light can have adverse consequences for any habitat in which it is found. For example, offshore oil platforms attract seabirds, usually to their detriment (Wiese et al. 2001, Montevecchi 2006). Terrestrial oil and gas facilities are often the only sources of light in remote open spaces. Parks can work with existing facilities to retrofit lights. For marine facilities, some initially positive data have been collected suggesting that using a green light on an offshore platform reduces the number of birds that are attracted to it (van de Laar 2007, Poot et al. 2008). By retrofitting the platform from white lights to green lights, Dutch researchers documented a reduction in the number of birds observed circling a platform (van de Laar 2007). The cause of this reduction could have been the wavelength of light used, or an overall decrease in lighting intensity that was a byproduct of the lighting change. The research shows that decreasing illumination and restricting the spectrum of light is a promising approach to reducing impacts to biological resources while still maintaining safe operations.

Indoor lighting

Although outdoor lighting is usually the focus of efforts to reduce impacts of night lighting on wildlife, indoor lighting should be considered as well. Indoor lighting may contribute substantially to ecological light pollution. In the extreme example of all-glass structures, greenhouses in Germany attract insects and migratory birds (Abt and Schultz 1995, Kolligs 2000). Furthermore, office buildings in urban cores can contribute as much to sky glow as billboards or roadway lighting (Oba et al. 2005). In darker environments, even the lights from a residence may have some effect on local wildlife behavior and degrade the experience of visitors in adjacent natural areas. Managers can be aware of these issues and seek to shield interior lights through use of curtains. This also gives an additional reason to cluster developments within parks. For urban areas and office buildings, guidelines are available to minimize the effects on birds, including through steps to reduce interior illumination (New York City Audubon Society 2007).

Lighthouses

The fatal attraction of birds to lighthouses has been observed for well over a century (Dutcher 1884, Miller 1897, Hansen 1954). In the United States, mortality of birds is more commonly reported on the East Coast than on the West Coast (Allen 1880, Merriam 1885), although mortality has been recorded on the West Coast as well (Squires and Hanson 1918). There has been some conflicting research on lighting color and flashing since the early 1900s (see review in Gauthreaux and Belser 2006), but the view has solidified that mortality can be decreased through the use of a flashing rather than constant light (Baldwin 1965, Jones and Francis 2003, Gauthreaux and Belser 2006). It is important that the light itself flashes, extinguishing completely between flashes, rather than the flashing effect being created by a rotating beam that remains illuminated. Reduction in lighting intensity also reduces bird mortality (Jones and Francis 2003).

Billboards

Billboards and other signage can affect wildlife behavior when illuminated. For example, light from a single billboard was sufficient to change the concealment behavior of juvenile salmon in a stream (Contor and Griffith 1995). While the significance of such behavioral changes is unknown, illumination of billboards and other signs should be controlled to minimize cumulative effects of lighting on wildlife, especially as digital billboards proliferate. Illumination from a typical digital

billboard proposed for installation in endangered species habitat in southern California would have caused lighting levels to exceed 10^{-1} lux (equivalent to that of a full moon) up to 1,000 ft (305 m) from the sign, according to the lighting engineers for the applicant (Longcore 2015; the proposal was not approved). Such intense lighting has the potential to influence nearby sensitive resources and contribute to sky glow.

Conclusion

Light pollution within parks and protected lands can have a measurable impact upon the habitat quality of the park, even if the light itself originates outside of the park's administrative boundary. Minimizing ecological impacts requires that land managers adopt an ethic of using only the minimum light necessary for human needs and being cautious when introducing light into or near a natural landscape. This report provides examples of the range of negative consequences that may arise from artificial night lighting. Though not a compendium of information for every species and every environment, it should provide adequate evidence for reasonable management of lighting in natural areas.

Park managers should first inventory their resources and determine if and where sensitive species or habitats exist. This information can then guide the development of the prescription of lighting zones within a park where different levels of lighting are allowed, depending on the uses and experiences desired for those zones. Lighting zones may be designed to minimize wildlife impacts only or also to integrate other aspects of a park experience. The most sensitive zone would have a prohibition on outdoor lighting or impose restrictions that define a narrow range of allowable artificial lighting. Looser restrictions that still provide adequate mitigation would be delineated for developed areas in parks and those with substantial human nighttime activity. In all instances, mitigation should address spectrum, intensity, direction, and duration. When all four aspects are addressed, mitigations can be effective at reducing ecological disruption from artificial night lighting.

California Partners in Flight wishes to thank the Packard Foundation for funding this important project. Many thanks to everyone who helped write, edit, and publish this document, and also those who contributed data. Many individuals and organizations volunteered time to this project and continue to support the mission of Partners in Flight. Special thanks to those who reviewed part or all of the plan: The California Oak Foundation, Ron Cowan, Walter Koenig, Kathy Purcell, Rich Reiner, Mark Reynolds, and Bill Tietje. Thanks also to Keyt Fischer, Claire Kremen, Kerri Frangioso, Melissa Duncan, David McCauley, Kristin Bruce, Jonathan Richard, Jay Mann, Susan Frankel, Hilary Cooke, John Alexander, Bill Hogoboom, and Colin Lee. Finally, thank you to The Wildlife Society for logistic support in the writing of this document and to the Oak Foundation for funding the first printing of version 2.0.

Executive Summary

This Oak Woodland Bird Conservation Plan is a collaborative effort of California Partners in Flight (CalPIF). It has been developed to guide conservation policy and action on behalf of oak woodland habitats and wildlife. The plan has focused on data concerning bird species that are dependent on oak woodlands, but conservation recommendations have broad applicability for all oak woodland habitats and, if implemented, would benefit many oak woodland species. The plan, which includes both this written document and an associated web site, is meant to provide a source of information on oak woodland bird conservation for landowners, managers, agencies and non-governmental organizations.

This conservation plan, along with the associated Geographic Information System (GIS) database of oak woodland habitats and monitoring data maintained at the Point Reyes Bird Observatory (PRBO), is the first iteration of a continuous process of updating habitat conservation recommendations based on the latest scientific monitoring and research data. This is not a regulatory document, nor does it represent the policies of any agency or organization.

A major extension of this conservation plan is the on-line GIS database of oak woodland monitoring projects and species breeding status available through the CalPIF section of PRBO's website at http://www.prbo.org/calpif/. Contributing to and managing data in this database is accomplished through a web interface, to which access is available by request. This database, in particular, is used for cataloguing new information and new analyses and for updating conservation recommendations and goals. Analyses of bird data will be posted on the PRBO website (www.prbo.org), periodically updated, and made available for use by the public. Therefore, this conservation plan is a dynamic, "living" document.

Biological Need

Oak woodlands have the richest wildlife species abundance of any habitat in California, with over 330 species of birds, mammals, reptiles, and amphibians depending on them at some stage in their life cycle (Verner 1980; Barrett 1980; Block and Morrison 1998). Wilson and others (1991) suggest that California oak woodlands rank among the top three habitat types in North America for bird richness. Oak woodlands are able to sustain such abundant wildlife primarily because they produce acorns, a high quality and frequently copious food supply (Koenig 1990; Ostfeld et al. 1996; McShea and Schwede 1993, and McShea 2000). Oaks also provide important shelter in the form of cavities for nesting (Waters 1988; Purcell 1995). Moreover, oak woodlands are among the most highly prized of California's

Acorn Woodpecker *photo by Ian Tait*

landscapes, for both aesthetic reasons and utilitarian needs such as firewood collection and grazing.

Yet, as with most of California's native habitats, oak woodlands have not escaped impacts from intensive human settlement: today only two-thirds of California's original oak woodlands remain (approximately 7 million acres). Of those, only about four percent enjoy protected status (Thomas 1997). This trend continues today, through loss of oak woodlands to urbanization and intensive agriculture such as vineyards (Tobin 1999, Larson 1999).

If loss of oak woodlands could be stemmed through protection and management incentives the problem might not be viewed as dire. However, oak woodlands are also faced with more insidious threats. Even today's existing oak woodlands in many cases are not regenerating naturally (i.e. young trees are not establishing to replace older trees as they senesce and die). Thus Californians continue to lose their oak woodland heritage, even in sites that are protected from development.

The causes of lack of natural regeneration are many, varied and inter-related in complex ways that are not completely understood. These include fire suppression (Biswell 1989; Stephens 1997) and overgrazing (Fleischner 1994; Belsky et al. 1999), both of which contribute to invasion of non-native annual grasses and cause long-term changes in habitat structure (Barnhart et al.1996). Annual grasses tend to outcompete native perennials and young oak seedlings for soil moisture, while herbivory by cattle can also stymie oak sapling development (Hamilton 1997).

The newest threat to California's oak woodlands is Sudden Oak Death (SOD). This pathogen started attacking California oaks in 1985 and became a full-scale epidemic by 1999. In the summer 2000, a previously unknown species of *Phytophthora*, the same genus responsible for the Irish potato famine, was identified as the pathogen causing SOD (Hansen et al. 2000). Oaks of many species infected with SOD die quickly, and there are currently no known cures or prophylactic measures for stopping the disease. The disease is currently present over more than 350 miles of California coastal forests (and into southern Oregon) and will most likely continue to spread (as it has recently to bigleaf maples in the Sierras).

Lack of recruitment of young oaks combined with the SOD epidemic affect 7 of the 10 acorn-bearing species of oak tree in California, including tanoak (Table 4-1). Thus, the combined effect of these two problems on native wildlife populations is likely to be considerable. Surprisingly, several recent assessments of biodiversity and environmental problems in the Unites States make no special mention of the major problems facing California's oak woodlands (e.g., Noss et al. 1995, Mac et al. 1998, Ricketts et al. 1999, Stein et al. 2000).

Mission and Objective

The mission of Partners in Flight (PIF) is to stop the decline of, maintain, or increase healthy populations of landbirds in North America. This mission translates into identification of habitat conservation and management priorities for bird species at risk in California, a priority of the associated Joint Ventures. By developing the Oak Woodland Bird Conservation Plan, California PIF (CalPIF) seeks to promote conservation and restoration of oak woodland habitat to support long-term viability and recovery of both native bird populations and other native species. The goals of the CalPIF oak woodland conservation effort are to:

- Define the conservation implications of three key problems facing California's oak woodlands: the long-term lack of recruitment, the new pathogen (*Phytophthora* sp.) that causes Sudden Oak Death, and the loss of oak woodland habitats.

- Collect data and analyze existing scientific information to inform land managers, planners, and the public of the complex and interrelated issues affecting California's oak woodlands and their management.

- Provide technical support for private landowners, land managers (state, federal, and non-profit), funders, agencies, and conservation organizations for assisting in the selection, design, and implementation of the highest priority conservation and land management actions.

- Support and inform efforts to increase the quantity (acreage) and quality (ecosystem function) of oak woodland habitat in California by providing funding information and promoting on-the-ground conservation projects.

Designing conservation efforts for oak woodland habitats based on the needs of birds is useful because birds occupy a diverse range of niches within oak woodlands: from those that nest on the ground to those that nest in the cavities of mature trees, those that feed primarily on insects and those that rely heavily on the acorn mast from year to year. Evidence and experience indicate that by managing for a diversity of birds, diverse oak woodland habitat structure will be maintained and many other elements of terrestrial biodiversity will be conserved (Martin 1995, Askins 2000).

CalPIF recognizes that the subject of land management and land use, whether on private or public lands, can be contentious. Because 85% of all oak woodlands are on private lands (Griffin and Muick 1990), CalPIF supports the need for land managers and landowners to have flexibility to develop systems that accommodate their needs while seeking to achieve the desired habitat characteristics that will maximize benefits to wildlife. CalPIF supports and will seek to maximize the benefits of new and ongoing efforts, such as the Integrated Hardwood Range Management Program, to work with viticulturists, ranchers, and public land managers with the ultimate goal of ensuring a thriving oak woodland heritage for future generations of Californians.

Findings and Recommendations

This Conservation Plan has been developed collaboratively by the leading bird researchers in California through a process designed to:

- capture the conservation needs of the complete range of oak woodland habitat types throughout the state, and
- develop biological conservation objectives for selected oak woodland bird species.

Lark Sparrow *PRBO*

At over 120 sites throughout California, monitoring data on oak woodland birds have been collected continuously over the past ten years. This document places an emphasis on a suite of seven bird species chosen because of their conservation interest to serve as focal species representative of the range of oak habitats in the state (Acorn Woodpecker, Blue-gray Gnatcatcher, Lark Sparrow, Oak Titmouse, Western Bluebird, Western Scrub-Jay, Yellow-billed Magpie). Visit http://www.prbo.org/calpif/ to view maps of oak woodland habitat coverage, focal species ranges and PIF monitoring sites in California. Preliminary analyses of the seven focal species' habitat requirements reveal the following:

- Four of seven focal species have experienced significant population declines, local extirpations, or both. The only species that appears to be significantly and consistently increasing is the Western Scrub-Jay, a bird that adjusts readily to urbanization but is also an important nest predator of many other native bird species.
- Loss of habitat or habitat structure (such as dead standing trees, mature trees with cavities, or a shrubby understory component) is implicated as a likely cause of decline and/or other problems for five of the seven focal species.

Accordingly, a series of conservation recommendations are provided, focusing primarily on protection, restoration and management of habitat that will facilitate and promote natural oak woodland regeneration. Other recommendations focus on the need to promote nest success, by retaining mature oaks in altered landscapes to provide nest cavities and by keeping down the number of native and introduced nest predators. Species-specific conservation recommendations for the Western Bluebird, Blue-gray Gnatcatcher and Acorn Woodpecker are also defined.

High priority conservation areas or "portfolio sites," distinguished by their protected status and potential for managing oak woodland habitat through restoration, are identified within

the ten bioregions of California as defined by the California Biodiversity Council. Setting conservation goals by bioregion facilitates planning site-specific projects in a broader context, and provides a comparable framework to other conservation planning efforts such as the North American Bird Conservation Initiative (NABCI). Setting and achieving conservation goals by bioregion will:

- Ensure that a suite of ecological communities representative of California's diversity will be conserved throughout the state.
- Ensure the broadest range of biodiversity and locally adapted races of species will be conserved.
- Facilitate action at the local level.

California's Oak Woodland Conservation Act provides funds for protection and conservation of oak woodlands. This program is administered by the Wildlife Conservation Board. It offers financial incentives to private landowners to protect and promote biologically functional oak woodlands over time. Conservation easements, land improvements, public education and outreach are some of the activities that may be funded by AB 242, initiated by the California Oak Foundation and carried by Assemblywoman Helen Thomson.

Finally, scientific efforts for conservation have little impact without the support of affected local communities, including private landowners, government land managers, and the general public (Askins 2000). This is particularly true for oak woodlands in California, which are 85% privately owned. To gain crucial public support, research and management programs must share their findings and involve the interested parties at all levels of the conservation enterprise. Therefore, this plan provides a list of current programs focusing on oak woodland conservation and management, educational and volunteer opportunities for children and adults, and a list of resources and organizations for those interested in involving their families and communities in oak woodland conservation.

Chapter 1. Introduction

The quintessential landscape of California is oak woodland. Oaks are the central features of the landscape that most Californians identify with. Yet, California's oak woodlands are imperiled in many ways. Moreover, the forces that put California's oaks at risk endanger the birds and other wildlife dependent upon them.

Blue Oak Woodland *photo by Sandy Scoggin, PRBO*

Oaks in Peril

The conservation concerns outlined here for oak woodlands, particularly the consequences of Sudden Oak Death, the lack of regeneration of several oak species, and the loss of oak habitat to development seem to be harbingers of the future for all the wildlife of California's oak woodlands.

Birds and Oaks

Coast Live Oak *photo by Rich Stallcup*

The birds of California's oak woodlands are connected to this distinctive habitat mainly through acorns, the fruits of oaks that are eaten and stored by dozens of species. This ecological relationship is reciprocal: species like Western Scrub-Jays, Steller's Jays, and Yellow-billed Magpies do not completely retrieve cached acorns and thus act as dispersers of oak seedlings across the landscape. In crucial ways, oaks provide key food for many birds, and some birds provide seed dispersal for oaks. Large oak trees also provide cavities for cavity-dependent nesting birds and other wildlife, as well as caching sites for acorn woodpeckers, nuthatches, and other species. Additionally, oaks commonly host mistletoe, which is an important food for Western Bluebirds, Phainopepla, and other species. The ties between oaks and birds are profound and diverse.

As is true for most natural landscapes, the loss of oak woodland habitat continues as our ever-growing population converts ranches into suburbia, foothills into vineyard, and forest into prime real estate. Further, the lack of recruitment of new oaks in many species represents a crisis in the making, but one that is not currently widely acknowledged. Nonetheless, our existing oak woodlands are frequently not regenerating new oaks to replace the old ones. Finally, a new threat dubbed "Sudden Oak Death," or SOD, is killing coastal oaks and tanoaks. This new pathogen represents a very urgent crisis indeed. The majority of California's oak tree species are affected either by lack of regeneration or SOD, or both (Table 4-1).

Partners in Flight

This Oak Woodland Bird Conservation Plan is part of a series of California Partners in Flight (CalPIF) Bird Conservation Plans. Bird scientists and ecologists working in oak woodlands have attempted to bring an understanding of these threats to California's oak woodlands and to discern how these issues are affecting and will affect the birds that are an integral part of these ecosystems. Perhaps unlike other CalPIF Conservation Plans, the primary focus here is on habitat problems over the immediate problems of the birds that inhabit them, but like other plans, conservation solutions are generally habitat based.

The Oak Woodland Bird Conservation Plan is an outgrowth of the national movement known as Partners in Flight (PIF). It is a plan produced by California Partners in Flight. CalPIF was formed in 1992 with the full participation of state, federal, and private land managers, scientists, and researchers interested in the conservation of nongame landbirds. Recognizing that the major cause of population declines in California was due to habitat loss, CalPIF began identifying critical habitats important to birds. The first effort was on riparian

habitat (see the "Riparian Bird Conservation Plan", PRBO website www.prbo.org for current information).

Objective of the Oak Woodland Bird Conservation Plan

The objective of the Oak Woodland Bird Conservation Plan is to promote conservation and restoration of oak woodland habitat in California to support the long-term viability and recovery of native bird populations and the associated natural diversity tied to oak woodlands. The main goals of our endeavor are to:

- Present an overview of the conservation implications of three key problems facing California's oak woodlands: the long-term lack of recruitment of many species of oaks and the recent pathogen (*Phytophthora* sp.) threat to tanoaks, coast live oak, interior live oak, and black oak (Sudden Oak Death), and the loss of oak woodland habitats.

- Collect data and analyze existing scientific information to help inform land managers, planners, and the public of the complex and interrelated issues affecting California's oak woodlands and their management.

- Provide technical support for private landowners, land managers (state, federal, and non-profit), funders, agencies, and conservation organizations for assisting in the selection, management design, and implementation of the highest priority conservation/land management projects and activities.

- Support and inform efforts to increase the quantity (acreage) and quality (ecosystem function; i.e., facilitate the regeneration of oaks and restoration of native perennial grasses) of oak woodland habitat in California by identifying and promoting on-the-ground conservation activities and projects (ones that are demonstrating success in habitat restoration and recruitment).

Chapter 2. Oak Woodland Habitats in California

Geologic History of Oak Woodlands

Oaks appeared in southwestern North America, including California, beginning in the Eocene (ca. 50+ million years before present) (Axelrod 1988). The history of oaks and oak woodlands in geologic time in California is a complicated one of community assembly and disassembly with the vicissitudes of climate change. In general, oaks increase in prominence in warmer, drier conditions, and decline in cooler, wetter conditions (Axelrod 1988). By the Miocene (ca. 24 million years before present) many of California's present oak species were evident (e.g., tanoak, coast live oak, interior live oak, blue oak, and valley oak).

Finer-scale fluctuations in oak abundance and distribution are evident in the Holocene (from 10,000 years ago to the present), as shown in pollen studies (Byrne et. al. 1991). Oaks began to reestablish themselves following the last glacial period in California. Oaks were more abundant than at present during the mid-Holocene (ca. 6,000 years ago).

Classification of Oak Woodland Types

Oaks are in the plant family Fagaceae. The members of this family include *Lithocarpus* (tanoaks, the majority of species (ca. 300) are in Asia), *Castanopsis* (now more frequently referred to as *Chrysolepis*) (the chinquapins), *Castanea* (chestnuts), and *Quercus* (oaks). All produce hardened fruits. Hardened fruit evolution in the Fagaceae and related families, the associated dispersal of such fruits by vertebrates, and a great explosion of plant diversity among such families all occurred in the Eocene (Tiffney 1986). *Lithocarpus* is considered the most plesiomorphic ("primitive") while *Quercus* is considered the most apomorphic ("advanced"), as evidenced from floral morphology (Kaul 1986).

There is a long history of classification of present vegetation in California (see review in Sawyer and Keeler-Wolf 1995). Holland (1986) identified 18 natural communities dominated by oaks in California. Six are forest communities (e.g., coast live oak riparian forest), four are chaparral communities (e.g., scrub oak chaparral), and eight are woodland and savanna communities (e.g., blue oak woodland and Oregon oak woodland).

In their own treatment of California vegetation, Sawyer and Keeler-Wolf (1995) note no fewer than 15 series of oak dominated by shrubs and 14 series of oak (and tanoak) dominated by trees; a total of 81 tree series are described in total. Among the tree series, the black oak, blue oak, coast live oak, mixed oak, Oregon white oak, tanoak, and valley oak series occur over significantly large areas of California.

Griffin (1988) noted that oak woodlands have "little floristic unity", but nonetheless partitioned oak woodlands broadly into "Foothill Woodland", "Southern Oak Woodland", "Northern Oak Woodland", and "Riparian Forest" region, with each category having several subcategories, or phases. In the Foothill type, valley oak, blue oak, and interior live oak predominate. It is in the Southern oak woodland type that we find coast live oak. Griffin's

main emphasis, however, is that oak woodland represents an "ill-defined zone of oak-dominated communities growing between open grassland and montane forest."

Thus, for our purposes, we define oak woodlands as simply those forests or woodlands where oaks (or tanoaks) are common or predominate. We wish instead to emphasize that for wildlife, including the bird community, the key issue of oak woodlands is not so much in the detail of which oak species are present, but rather that all oaks (and tanoaks) produce acorns. Acorns are perhaps the most important food product for wildlife produced in California's many diverse habitats.

Blue Oak Acorns *photo by Steve Zack, Wildlife Conservation Society*

The diverse oak woodland types in California support a range of bird communities. For example, coastal oak forests in western California support high breeding densities of forest species, such as Dark-eyed Juncos, that are not common in oak savanna habitats further inland, although both habitats support many oak-associated species such as Oak Titmouse (Tietje and Vreeland 1997, Verner et al. 1997).

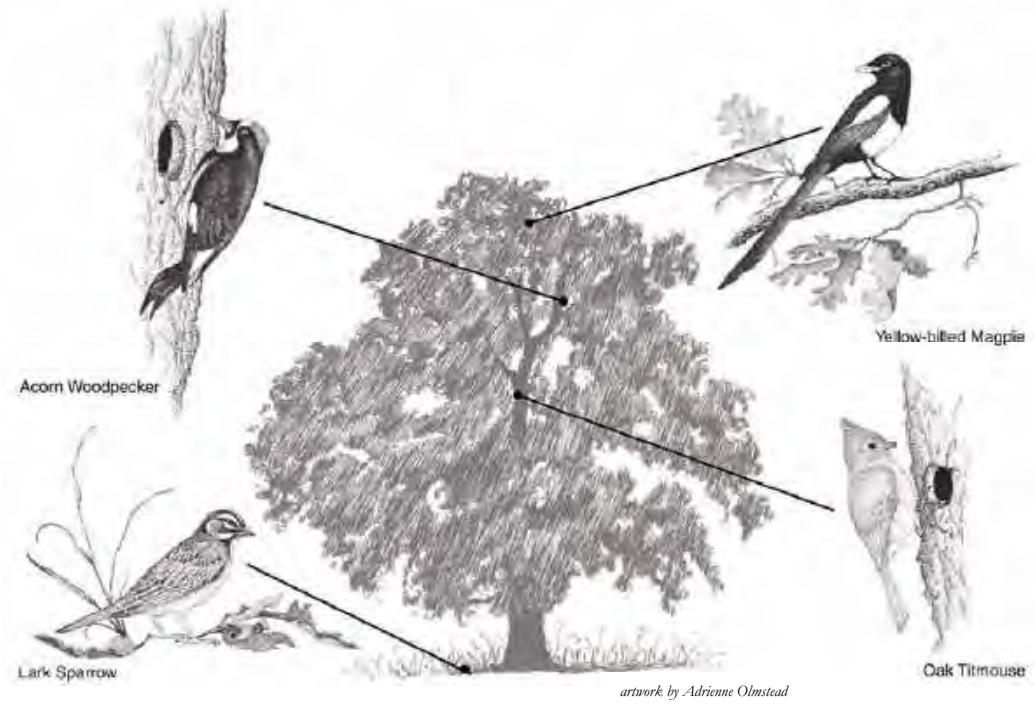
[a] Davis et al. (1998)

Chapter 3. Conservation Planning Process



Oak woodlands are thought to have the richest wildlife species abundance of any habitat in California, as some 331 species depend on this habitat to varying degrees (Verner 1980; Barrett 1980; Block and Morrison 1998). The key connection between much of the wildlife and oak woodlands is through the oak's production of acorns. Acorn production varies in time and space between and among species (Sork and Bramble 1993; Healy et al. 1999), including species in California (Koenig et al. 1994). So-called "mast" years in oaks, when acorn production is copious in an area, are critical to triggering pulses in vertebrate populations and reproduction (Koenig 1990; Ostfeld et al. 1996; McShea and Schwede 1993; and McShea 2000). Forests with at least some oaks have higher mean vertebrate diversity than similar forests without oaks (Rosenstock 1998). This difference is due both to acorn production and the increased cavity-nesting sites afforded by large oak trees in the landscape.

Importance of Oak Habitats for Wildlife

Large oak trees in oak woodland habitats are important for cover, nesting sites for cup nesting species and cavity nesting species, as well as caching sites for birds storing acorns. In oak woodlands with large oaks, the abundance of cavity nests is important to many species of wildlife, including birds (Waters 1988; Purcell 1995). Old, large oak trees are mosaics of living and dead branches, providing ample sites for woodpeckers to excavate cavities. Dead branches and trunks in both living and dead large oaks are critically important for storage sites of acorns by Acorn Woodpeckers (Gutierrez and Koenig 1978).

There are a few studies of bird communities in California's oak woodlands (Block 1989; Block et al. 1990; Tietje et al. 1997; Verner et al. 1997; Sisk et al. 1997). These studies indicate many of the ecological connections between oak woodlands and birds. They make clear the strong link between the bird community and the production of oaks (through acorn dispersal), the importance of cavity nests in large trees, and the often complex interactions and connections between habitat features and bird species.

Fragmentation studies and efforts to identify minimal size and shape requirements of oak woodland habitat are few but important (see for example Aigner et al. 1998, Merenlender et al. 1998, Stralberg and Williams, 2002). Land managers need to know tradeoffs in habitat size and the consequences for wildlife. Restoration efforts can also be guided by knowing how many species might be present with what effort of scale.

artwork by Adrienne Olmstead

Birds in Oak Woodlands
This schematic shows nest placement for four of the plan's focal species. Studies show a strong link between the bird community and the production of oaks (through acorn dispersal), the importance of cavity nests in large trees, and the often complex interactions and connections between habitat features and bird species.

Focal Species

Because birds occupy a wide diversity of ecological niches, they serve as useful tools in the design of conservation efforts (Martin 1995, Askins 2000). Birds are relatively easy to monitor in comparison with other taxa and can serve as "focal species", whose requirements define different spatial attributes, habitat characteristics and management regimes representative of a healthy system**.** For example, the bird that requires the largest area to survive in a certain habitat will determine the minimum suitable area for that habitat type. Likewise, the requirements of non-migratory birds that disperse short distances to establish new territories will define the attributes of connecting vegetation. The species with the most demanding or exacting requirements for an ecological characteristic such as territory size determines its minimum acceptable value in an area that is protected or managed for biodiversity. Therefore, the assumption is that a landscape designed and managed to meet the focal species' needs encompasses the requirements of other species (Lambeck 1997).

Because focal species lists are explicitly based on numerous hypotheses and assumptions, the choice of focal species should be tested as part of the ongoing adaptive conservation planning process. Thus, this oak woodland focal list may be revised in the future to include new species identified by research and monitoring.

Twenty-two bird species were selected by consensus as "focal species" for preparing the Oak Woodland Bird Conservation Plan. The focal species list for oak woodlands includes both a suite of species representing various habitat elements and ecological characteristics and a number of species that are good indicators for monitoring (species that are common and respond strongly and/or consistently to habitat attributes). Unlike the Riparian Bird Conservation Plan, none of the "focal species" have any special status designations. Species accounts have been prepared, or are in process, for the following bird species:

Focal Species and Species Account Authors:

- **Acorn Woodpecker** (***Melanerpes formicivorus***) by Corrina Lu and Colin Lee, California Partners In Flight

- **Blue-gray Gnatcatcher** (***Polioptila caerulea***), by Diana Humple, Point Reyes Bird Observatory

- **Western Scrub-Jay** (***Aphelocoma californica*)** by Sue Guers, Point Reyes Bird Observatory

- **Yellow-billed Magpie** (***Pica nuttalli***) by Mark Reynolds, Ph.D., College of Sciences, San Diego State University

- **Oak Titmouse** (***Baeolophus inornatus***) by Moe Flannery, Point Reyes Bird Observatory

- **Western Bluebird** (***Sialia mexicana***) by Mike Lynes, Point Reyes Bird Observatory

- **Lark Sparrow** (***Chondestes grammacus***) by Diana Humple, Point Reyes Bird Observatory

Additional focal species of similar conservation concern have been identified, but species accounts have not yet been completed for these species. We anticipate and encourage future accounts for these species.

Additional Focal Species:

- **Wood Duck (*Aix sponsa*)**
- **Red-shouldered Hawk (*Buteo lineatus*)**
- **Wild Turkey (*Meleagris gallopavo*)**
- **California Quail (*Callipepla californica*)**
- **Band-tailed Pigeon (*Columba fasciata*)**
- **Northern Pygmy Owl (*Glaucidium gnoma*)**
- **Lewis Woodpecker (*Melanerpes lewis*)**
- **Nuttall's Woodpecker (*Picoides nuttallii*)**
- **Ash-throated Flycatcher (*Myiarchus cinerascens*)**

- **Hutton's Vireo (*Vireo huttoni*)**
- **White-breasted Nuthatch (*Sitta carolinensis*)**
- **Bewick's Wren (*Thryomanes bewickii*)**
- **California Thrasher (*Toxostoma redivivum*)**
- **European Starling (*Sturnus vulgaris*)**
- **California Towhee (*Pipilo crissalis*)**

Ecological Relationships

The birds on our lists represent diverse ecological relationships with California's oak woodlands (Tables 3-1 and 3-2). Many of the bird species consume acorns. Clearly, species like Acorn Woodpeckers (Koenig 1990), Western Scrub-Jay and Oak Titmouse are highly dependent on acorns. Verner (1980) names 30 bird species as consumers of acorns, six of which have diets that are more than 25% acorns. Acorn Woodpeckers and Western Scrub-Jays cache (store) many thousands of acorns annually. Western Scrub-Jay individuals may store as many as 5,000 acorns annually (Vander Wall 1990), whereas a population of Acorn Woodpeckers may store up to 43,000 in a year (Koenig 1990; Vander Wall 1990). The Western Scrub-Jay, Steller's Jay (not on our lists; see Fuchs et al. 1997), and, to a lesser degree, the Yellow-billed Magpie cache acorns individually in the ground, and thus, among caching birds, are the only species to facilitate regeneration because many acorns remain unretrieved and germinate.

Western Scrub-Jay

Wildlife Conservation Society

Table 3-1. Birds associated with oak woodlands in California, with information on their use of acorns, nesting substrate, general foraging habitat in oak woodlands, and whether the species is endemic to California.

Species	Consumes Acorns?	Caches Acorns?	Nest[1]	Foraging Habitat in Oak Woodlands	California Endemic?
Wood Duck	**Yes**		**2º Cavity**	Wooded Streams	
Red-shouldered Hawk			Platform	Woodlands	**?**
Wild Turkey (I[2])	**Yes**		Ground	Woodlands	
Band-tailed Pigeon	**Yes**		Platform	Woodlands	
California Quail	**Yes**		Ground	Woodland-shrub	
N. Pygmy Owl			**2º Cavity**	Woodlands	
Acorn Woodpecker	**Yes**	Tree, many	**1º Cavity**	Woodlands	
Lewis Woodpecker	**Yes**		**1º Cavity**	Woodlands	
Nuttall's Woodpecker	**Yes**		**1º Cavity**	Woodlands	**YES[3]**
Ash-throated Flycatcher			**2º Cavity**	Open Woodlands	
Western Scrub-Jay	**Yes**	**Ground, many**	Cup	Woodland-Scrub	
Yellow-billed Magpie	**Yes**	**Ground, few**	Cup	Woodlands	**YES**
Oak Titmouse	**Yes**	Tree, few	**2º Cavity**	Woodlands	**YES[3]**
White-breasted Nuthatch	**Yes**	Tree, few	**2º Cavity**	Woodlands	
Bewick's Wren			**2º Cavity**	Woodland-Scrub	
Blue-gray Gnatcatcher			Cup	Woodlands	
Western Bluebird			**2º Cavity**	Open Woodlands	
California Thrasher			Cup	Woodland-Scrub	**YES[3]**
European Starling (I)			**2º Cavity**	Agriculture edge	
Hutton's Vireo			Cup	Woodlands	
California Towhee			Cup	Woodland-Scrub	**YES[4]**
Lark Sparrow			Ground	Grass - Woodland	

Notes: 1. Cavity nesting species differ as to whether they excavate their own cavities (1º cavity nester) or they take over disused nests or naturally occurring cavities (2º cavity nester). 2. (I) denotes an introduced, nonnative species. 3. Also occurs in Baja California, Mexico. 4. Also occurs in Baja California, Mexico, and extreme southern Oregon.

Table 3-2. Essential habitat elements for focal species, based on California Wildlife habitat Relationships System Version 7.0.[1]

Focal species	Acorns	Cavities	Trees	Shrub	Grass/ herb	Snags	Brush piles	Water/ Riparian
Wood Duck		X						X
California Quail			X	X	X		X	X
Red-shouldered Hawk			X	X				X
Northern Pygmy Owl		X	X			X		
Band-tailed Pigeon	X		X

Hutton's Vireo			X	X				X
Lark Sparrow					X			
California Towhee				X				X

[1] Includes selected elements classified by CWHR as "essential" or "secondarily essential".

Half of the birds on our lists are cavity-nesting species. Their dependency on particularly large oak trees, with their mosaic of live and dead branches, the latter containing the cavities for nesting, cannot be overestimated (Purcell 1995). Acorn Woodpeckers are the most common cavity excavating species in oak woodland habitats, particularly the valley, blue, black and interior live oak woodlands. The secondary cavity nesting species, those that do not excavate their own cavities, typically appropriate unused woodpecker nesting cavities. Cavities can and often are used for many years, often by many species over time.

Acorn Woodpecker *photo by Ian Tait*

Several bird species were chosen that respond to specific types of understory habitat within oak woodlands, including Lark Sparrow, Bewick's Wren, and California Quail. The list also includes several species that are sensitive to habitat fragmentation and residential development density: Lark Sparrow and Ash-throated Flycatcher respond negatively, and Western Scrub-jay responds positively (Stralberg and Williams, 2002).

Several bird species on our lists are endemic (unique) to California, or nearly so (it is uncertain whether Red-shouldered Hawks of California are distinct from eastern hawks). And, of these, the Nuttall's Woodpecker, Yellow-billed Magpie, and Oak Titmouse are intricately tied to oak woodlands specifically. Several birds on our focal list use habitat elements such as woody debris or shrubs (Bewick's Wren, California Towhee) and others use wetland or riparian habitat elements (Red-shouldered Hawk and Wood Duck). These components of oak woodland habitats are also important to many species of mammals, amphibians and reptiles in oak woodlands.

Nuttall's Woodpecker *photo by Ian Tait*

Two species are non-native, and enter our list and consideration for different reasons. The Wild Turkey is an important game bird in California and an important consumer of acorns. The European Starling is included because it is a major competitor for cavities in oak woodlands. It is typically more aggressive than other species, and so prevents native cavity nesting species from accessing nesting sites. As many of our oak woodlands abut agricultural areas, they are susceptible to colonization by Starlings - an abundant pest with which our native species must contend.

Figures 3-1 through 3-7 show oak woodland distribution in California based on the California GAP Analysis (Davis 1998), current range, historic range, study sites and breeding status at these sites for the primary focal species, Acorn Woodpecker, Blue-gray Gnatcatcher, Lark Sparrow, Oak Titmouse, Western Bluebird, Western Scrub-Jay, and Yellow-billed Magpie.

Chapter 4. Problems Affecting Oak Woodland Birds

Habitat Loss

More than a third of all oak woodlands have been lost since the settlement of California by Europeans; of an estimated 10-12 million acres, only some seven million remain. Of the remaining oak woodlands, most have been modified or degraded, and only about four percent are formally protected (Thomas 1997). Most of the loss of oak woodlands has been due to the ever-increasing urban and suburban growth of California. The city of Oakland, the town of Thousand Oaks, and many other town names recall the former prevalence of oak woodlands, and their importance to earlier communities. The clearing of oaks has also been done on ranches to "improve" forage quantity (Bolsinger 1988), and for firewood (Bolsinger 1988; Griffin and Muick 1990; Aigner et al. 1998).

Yellow-billed Magpie on oak stump *photo by Ian Tait*

A comparatively new challenge to conservation of oak woodlands is loss to expanding vineyards. A recent example in Santa Barbara County where a prominent winery removed a small grove of oaks, causing a backlash among citizens (Van de Kamp 1996, 1997; Burns 1998a, b; Sage 1998a, b), provides evidence for the value that Californians place on their remaining woodlands and large oak trees. The accelerated clearing of oak trees in rural areas of Santa Barbara County led to the initiation of a collaborative process to develop a new oak protection ordinance (Leider in press). The wine industry is attempting to come to grips with this conflict of economic growth and the aesthetic and biological effects of oak clearing (Tobin 1999; Larson 1999). For example, the California Association of Winegrape Growers (CAWG) hosted a workshop on the interaction between wildlife and vineyards in February 2002. CAWG plans to publish a guide to wildlife-friendly vineyard management that will present case studies and resources for growers. Adina Merenlender and others from the Integrated Hardwood Range Management Program are working with vineyard owners to identify ways to manage oaks in and around vineyards (Merenlender et al, 1998).

Lack of oak regeneration

A major threat to the oak woodlands of California is that several species have experienced very little regeneration this past century (White 1966; Griffin 1971, 1976). This general problem is not unique to California (Watt 1919, for problems in Britain's oak woodlands). The problem is not in acorn production or acorn viability, rather it is in the inability of seedlings to survive to become young trees (Borchert 1990). The causes and influences of this phenomenon are many and interconnected. It is a "cryptic" conservation crisis because it is not clearly evident as one looks across the oak woodland landscapes that surround so many of California's population centers. The classic park-like appearance of many oak

woodlands seems intact – large trees spreading over grassy areas. But, upon closer inspection, little to no young trees are growing. In fact, in many areas, small trees are old trees of suppressed growth, not recent recruits. The consequence for several species of oaks is that existing trees will senesce, die and not be replaced unless there is active management for a different outcome.

There are several factors that contribute to this problem, and each interacts with others in ways that are often not fully understood. The factors include fire suppression, cattle grazing, invasion of European weedy annual grasses that have largely replaced native perennial grasses, and herbivory of oak shoots by cattle and native mammals.

The tree oaks known to have serious problems with lack of regeneration include valley oak (Thompson 1961), blue oak (Swiecki and Berhhardt 1998), coast live oak (Parihk and Gale 1998), and island oak (Pavlik et al. 1991) (Latin names are provided in Table 4-1). Grazing pressure is greatest where valley oak and blue oak occur. Some regeneration problems have been observed in some regions for black oak. There has been intensive research and some multiple management solutions to the recruitment problem. There is a large and diverse literature available on facilitating regeneration in oak trees, through such diverse means as seedling shelters from grazing, prescribed fire, progressive cattle management and other techniques that vary in management intensity (Adams et al. 1997; Alpert et al. 1999; Bernhardt and Swiecki 1997; Borchert 1990; Callaway 1992a,b; Gordon and Rice 1993; Griggs and Peterson 1997; Holmes 1996a, b; Jansen et al. 1997; Larsen and Johnson 1998; McCarthy 1993; McCreary and Tecklin 1997; Momen et al. 1994; Muick 1990, 1997; Parikh and Gale 1998; Phillips et al. 1997; Plumb and De Lasaux 1997; Rogers and Johnson 1998; Schwan et al. 1997; Standiford et al. 1997; Strong and George 1990; Swiecki et al. 1997a, b; Swiecki and Bernhardt 1998; Techlin et al. 1997.)

The key issue of the regeneration problem is that many diverse solutions have been identified and implemented (citations above). Management of oak recruitment can be and has been successful; the challenge is in facilitating large-scale implementation, particularly in collaborating with private landowners that collectively hold the vast majority of oak woodland habitat.

Fire and oak woodlands

Fire and oak woodlands are profoundly tied together in evolutionary and ecological ways (Reich et al. 1990; Abrams 1992; Stephens 1997). Frequent, low intensity fires gave oak woodlands in and around the Central Valley their open, park-like appearance. Frequent fires acted to thin out the understory of shrubs and small trees, and thus provide less competition for soil nutrients and water among larger, established oaks. Fire suppression arrived with European settlement. Prior to European settlement, Native Americans of California had augmented natural fire regimes by setting fires, often on an annual basis, for a variety of reasons, including to facilitate an increased acorn harvest (see Biswell 1989; McCarthy 1993). Fire suppression began in earnest in California early in the 20th century (Biswell 1989). Although California has devastating fires annually, the overall effect of fire suppression has

led to widespread changes in forest and woodland structure and function (Biswell 1989, Bonnicksen 2000).

Another effect of fire suppression on oaks is the change in vegetation structure that arises as a result. For example, fire suppression has led to an increase in incense-cedar (*Calocedrus decurrens*) and white fir (*Abies concolor*) in Yosemite National Park, which in turn has reduced the density of black oaks there (Phillips et al. 1997). In northern California, fire suppression has led to increased densities and a lower elevation occurrence of Douglas-fir (*Pseudotsuga menziesii*) at the expense of white oak, which has declined in number (Barnhart et al. 1996) This scenario is also true in the Willamette Valley of Oregon (Johannessen et al. 1971).

Over-grazing by Cattle

Over-grazing by cattle has been shown to have multiple and strong detrimental effects to ecosystems in the West (see reviews by Fleischner 1994; Belsky et al. 1999). Over-grazing has severely disrupted ecosystem structure and function generally (Fleischner 1994), and in California oak woodlands as well (Stromberg and Griffin 1996; Jackson et al. 1998; Swiecki and Bernhardt 1998). Over-grazing by cattle has directly and indirectly facilitated the invasion of weedy (European) annual grasses and the associated decline (and often loss) of native perennial grasses (Hamilton 1997). The weedy annual grasses compete for soil moisture with oak seedlings. Cattle also consume young oak shoots, as do feral pigs and native wildlife like pocket gophers and deer.

Dead Tanoak *photo by Steve Zack Wildlife Conservation Society*

Sudden Oak Death

The newest threat to our California oaks emerged very dramatically in recent years. Tanoaks in Marin County were found to be dying in 1995 (Svihra 1999a,b,c). Soon, varied reports on tanoak death were noted elsewhere in the coastal forests of the Bay Area. In 1999, at a CalPIF meeting at Pfeiffer State Park in Big Sur, participants noticed the majority of tanoaks there were dead, conspicuous with their brown leaves still clinging to the trees. Soon, others noted that coast live oaks and black oaks near infected populations of tanoak were also showing similar symptoms and dying. The disease was christened as Sudden Oak Death Syndrome or SODS, and now is generally known simply as Sudden Oak Death or SOD.

In 2000, pathologist Prof. Dave Rizzo of University of California, Davis, isolated the pathogen and discovered it to be a previously unknown species of *Phytophthora* (Standiford 2000). *Phytophthora* is a fungus-like pathogen of the same genus that caused the Irish potato famine and that has been attacking Port-Orford-cedar (*Cupressus lawsoniana*) to the risk of extinction (Hansen et al. 2000, Fimrite 2000). A *Phytophthora* species has attacked Mediterranean oaks (Brasier 1996), another species has crippled alders (*Alnus* spp) in Europe (Cech 1998), another is attacking *Eucalyptus* forests in Australia (Hansen 1999), and the genus has been a serious pest to innumerable agricultural crops worldwide (Erwin and Ribeiro 1996).

Sapwood bleeding *photo by Steve Zack, Wildlife Conservation Soc.*

The *Phytophthora* attacking California's oaks results in very distinctive symptoms. The symptoms include dark discolored patches of bark on the lower trunk, often exuding a reddish sap ("sap bleeding"), the presence of fruiting bodies of the fungus *Hypoxylon* sp., and the frass of bark and ambrosia beetles (*Coleoptera*: *scolytidae*). The leaves turn brown quickly (Svihra 1999a,b,c; Standiford 2000). This particular *Phytophthora*'s DNA does not match any known species, raising the possibility of it being a new pathogen through interspecific hybridization (see Brasier et al. 1999) or a new mutant form of an existing or introduced pathogen. Different *Phytophthora* spp. have been isolated from diseased oaks in California before this problem (Raabe 1990), but they have not caused anything near the widespread infestation and death that this new pathogen has. Brasier (1996) argues that global warming enhances the oak decline in southern Europe, caused by *Phytophthora cinnamomi*.

To date, valley oaks, blue oaks, and Oregon oaks show no symptoms of SOD. Thus, it seems possible that only those oaks in the "Red" group, plus *Lithocarpus* tanoaks, (Tucker 1980) are susceptible, while those of the "White" Group are immune (Table 4-1).

Phytophthora species are oomycetes and now placed in their own Kingdom, Chromista, with another genus (Erwin and Ribeiro 1996), and are no longer considered true fungi because of their distinctive flagella and DNA. Their zoospores are mobile in moist soil and water, which can become resting spores (oospores and chlamydospores) in drier conditions. In the case of *P. lateralis*, the agent killing Port-Orford-cedar, the spores are easily transported by vehicles between watershed on the mud of tires, and by wildlife and cattle, as well as hikers and others in the woods.

During the summer of 2000, a research team sponsored by the *Wildlife Conservation Society* investigated the geography of the SOD epidemic. *WCS* surveyed the range of tanoak for the presence or absence of symptoms. The native range of tanoak runs along coastal forests in southern Oregon, down through coastal California to just north of Santa Barbara, with isolated populations in the Klamath Mountains and in the Sierras (Tappeiner et al. 1990). The team combined roadside surveys with plot samples. Preliminary results indicated that the disease was evident over some 350 miles of California coastal forest. Subsequent pathology studies have indicated that a different *Phytopthora, P. illisis*, may be responsible for symptomatic trees in northern California. Then, the northern boundary of symptomatic trees was at Humboldt Redwoods State Park, just south of Eureka, and symptomatic trees of all three species were found in regular patches along coastal forests to the Santa Lucia Range north of San Simeon (Steve Zack, unpublished data.). Currently (April 2002), the disease has spread to southern Oregon (although very local and patchy there) and to the Sierras (detected in Bigleaf Maples, but not yet in tanoaks or oaks there) (see the website www.suddenoakdeath.org for updates on range and species affected by the pathogen). Preliminary results from 2000 also reveal considerable regional variation in the extent of the disease. In northern California, approximately 10 percent of the tanoaks had disease symptoms, whereas in Big Sur (Pfeiffer State Park) nearly 90 percent were dead or diseased.

Dead Coast Live Oak – Felton, California *photo by Steve Zack, Wildlife Conservation Society*

Other areas particularly hard hit (ca. 40-45% of trees were symptomatic or dead) are tanoaks at Muir Woods National Monument, coast live oaks at China Camp State Park (near San Rafael), and tanoaks at Henry Cowell Redwoods State Park (in Felton). It is clear that this pathogen has spread very quickly, perhaps more quickly than other tree epidemics known in North America (Little 1995). It is not all clear if the disease is still spreading as quickly as in the late 90's or if healthy trees in infected areas are immune. Unfortunately, it seems reasonable to guess that the disease would continue to spread north, as it seems to have spread very far very fast. It would also seem that the percentage of infected trees will likely grow such that northern infected populations may become more similar to those around Marin County and at Big Sur.

The effect on wildlife of this die-off of tanoaks and oaks in coastal California is inestimable. With nearly 90% of tanoaks dead in Pfeiffer State Park in Big Sur, the loss of tanoaks to animals as diverse as black bear, deer, California Quail, and Steller's Jays, plus the several score of other species directly or indirectly dependent on acorns will be dramatic. The *Wildlife Conservation Society* is undertaking studies of wildlife effects of this pathogen in coastal California.

Oak Woodland Viability

The joint concerns of lack of recruitment and the new SOD epidemic dramatically affect most of the nine *Quercus* oak tree species and tanoak in California (Table 4-1). Of the ten acorn-bearing trees, seven have one or both of the problems, with black oak and coast live oak afflicted by both (Table 4-1). Solving the problem of lack of recruitment of white oaks, such as Valley oak and Blue oak, is especially important given that they appear to be unaffected by SOD, and therefore may be critical to the long-term viability of oak woodland-dependent wildlife.

The striking need for progressive management of California's oak woodlands is challenging for those concerned with oaks and wildlife. Yet, it must be recognized that 85% of oak woodlands are on private lands (Griffin and Muick 1990), and thus the capacity to manage these lands professionally and consistently varies and is challenging, to say the least. Working with private landowners is a significant challenge for conservationists (Knight 1999; Dale et al. 2000), but essential to guaranteeing a future of viable oak woodlands and wildlife in the future (Askins 2000).

Recent volumes directly concerned with the California landscape have raised concerns of oak woodland viability, particularly the recruitment problem (Barbour et al. 1993; Pavlik et al. 1991; Johnston 1994). The Oaks of California by Pavlik et al. (1991) is a particularly beautiful and well-designed book. Within Calfornia, a few conservation planning efforts have singled out oak woodlands, including the Nature Conservancy's ecoregional plans and the Sierra Nevada Ecosystem Project.

Surprisingly, other recent assessments of biodiversity and environmental problems make no special mention of the major problems facing California's oak woodlands, particularly the recruitment problem (Sudden Oak Death is too new). For example, a major overview of

imperiled ecosystems in the United States by Noss et al. (1995) has no significant discussion of California oaks, but cites only a 14% loss of hardwood woodlands (Bolsinger 1988), and cites the 99.9% loss of "riparian oak woodland" (those dominated by valley oak, Martin 1986). A two volume effort to assess the nation's biological resources by the U.S. Geologic Survey (Mac et al. 1998) makes scarce mention of oak woodlands in it's California section. The recent assessment of habitats and biodiversity by the *Nature Conservancy* (Stein et al. 2000) makes no particular mention of California's oak woodlands. Likewise, a major assessment of North America produced by the *World Wildlife Fund* (Ricketts et al. 1999) emphasizes much of California's distinctive endemic diversity, but again makes no particular mention of California's oak woodlands.

Less attention may be given to oak woodlands than to other habitats, such as riparian or coastal sage scrub, which are inhabited by numerous species of special concern. However, oak woodlands are especially well-loved and support a large diversity of animal and plant species. Clearly, the issue of oak woodland viability still needs considerably more recognition before it can be adequately addressed.

photo by Steve Zack, Wildlife Conservation Society

Table 4-1. The Oak Trees (and Tanoak) of California and the presence/absence of conservation problems discussed in the text.

Common Name	Latin Name	Group[1]	General Distribution in California[2]	Recruitment Problems?[3]	Infected by SOD?[4]
Tanoak	*Lithocarpus densiflorus*	--	Coastal forests, spotty in Klamaths and Sierras		Yes
Black Oak	*Quercus kelloggii*	Red	Northern foothills	Occasional	Yes
Blue Oak	*Quercus douglasii*	White	Central Valley foothills, dry coastal	Yes	
Canyon Oak	*Quercus chrysolepis*	Interm.	Foothills throughout state		
Coast Live Oak	*Quercus agrifolia*	Red	Central, southern coastal forests	Yes	Yes
Engelmann Oak	*Quercus engelmannii*	White	Extreme southern, coastal CA		
Interior Live Oak	*Quercus wislizenii*	Red	More interior foothills		Yes
Island Oak	*Quercus tomentella*	Interm.	Channel, Guadelupe Islands	Yes	
Oregon Oak	*Quercus garryana*	White	N CA (coastal and Klamaths), spotty along Sierras		
Valley Oak	*Quercus lobata*	White	Central Valley, dry coastal	Yes	

Notes:

1. Taxonomic group (from Tucker 1980: Red oaks are those with pointed lobes and densely hairy inner shells of acorns, among other characteristics; White oaks have round lobes and smooth inner shells of acorns, among other characteristics; Intermediate oaks (Interm.) are just that with respect to characters.)
2. The general distribution was described from range maps of *Lithocarpus* from Tappeiner et al. 1990, and of *Quercus* in Pavlik et al. 1991.
3. If recruitment (regeneration) is problematic for oaks, as noted by studies from the literature, a "Yes" or "Occasional" is entered in the column.
4. If oaks have been observed to have symptoms of the new *Phytophthora* infection (Sudden Oak Death), a "Yes" is entered in the column.

Chapter 5. Species-Specific Recommendations and Population Targets

The birds of California's oak woodlands share many of the same needs and threats. Large-scale conversion due to urbanization and expanding industrial agriculture continues to rapidly reduce available habitat. Human encroachment subsidizes nest predators such as raccoons, rats, and skunks and introduces exotic species of plants and animals, including domestic cats, European Starlings, and House Sparrows. These invasive bird species often out-compete native cavity-nesting birds resulting in reproductive failure and out-right extirpation of local breeding birds. Finally, the apparent problem of oak regeneration threatens the future generations of all birds reliant on oaks.

Species-Specific Recommendations

In preparation for this conservation plan, CalPIF developed a series of species accounts on a suite of oak-associated bird species in California. Species were chosen because they represented niches and particular habitat needs, with the rationale that they represented other species with similar requirements. These detailed accounts described historical and current ranges, life history traits, habitat needs, and management concerns for each species. The accounts are available as electronic appendices to this plan at http://www.prbo.org/calpif/. Below are recommendations, derived from these accounts, for five of the focal species.

Although CalPIF strongly endorses the concept of multiple-species management, it recognizes that the needs of select focal and secondary species, representative of the different aspects of California's oak woodlands, may need to be specifically addressed. It also recognizes that managing for the specific requirements of some species is likely to affect, in either positive or negative ways, other species in the community. The challenge is that conservation actions must attempt to benefit multiple species while simultaneously tailoring their management activities for birds with very specific requirements.

One of the consistent issues raised with oak-associated birds is the need for further research into their habitat needs and management concerns. These recommendations need to be implemented, monitored, and altered as necessary. As this plan is a "living document," so are these recommendations. With future research, management decisions can be made that best benefit both the birds and humans using oak woodlands.

Lark Sparrow *(Chondestes grammacus)*

Population:

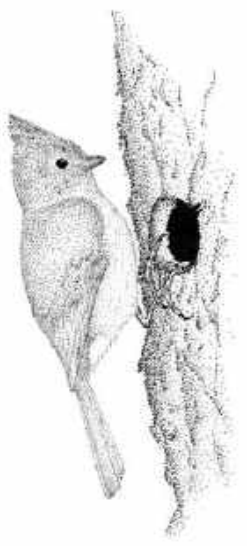
Lark Sparrow *artwork by Adrienne Olmstead*

One of California's most beautiful sparrows, the Lark Sparrow often frequents open woodlands and grasslands. It usually nests on the ground, though it makes frequent use of available shrubs for perching and foraging. Overall in North America, its population appears reduced since 1968, and some data indicate decline in California's oak-dominated foothill region and in grasslands (Sauer et al. 2000). Local extirpations may be due to habitat loss and other problems of human encroachment. Still, the Lark Sparrow continues to occupy much of its historic range.

Management:

Fire Management:
Managed burns that reduce the vegetative density of an area may encourage habitation by Lark Sparrows. However extremely hot fires may reduce potential nest sites and kill the native plant communities upon which this species relies. Fire suppression may allow the growth of overly dense habitat unsuitable to Lark Sparrows.

Brown-headed Cowbird Parasitism:
Lark Sparrows frequently host Brown-headed Cowbirds and suffer reduced productivity. Efforts to manage for cowbirds would likely benefit this species.



Pesticides:
Insects compose nearly 25% of the food matter consumed by this species. This species is known to nest in active agricultural areas, including row crops and orchards. Pesticide application in these areas may reduce prey availability and have other deleterious affects. More study in this area is needed.

Invasion of Exotic Vegetation:
In some areas, Lark Sparrows no longer breed where native vegetation has been replaced by invasive exotic grasses. Along with many other plants and animals, they would benefit from efforts to control exotics and restore native vegetation.

Disturbance:
Because they prefer to nest on the ground, Lark Sparrows are particularly vulnerable to such disturbance as grazing, off-trail recreation, burning, and mowing. Their nests are also

exposed more readily to predators such as domestic cats, raccoons, and dogs. Managers should take steps to limit this kind of disturbance during the breeding season (March through August).

Research Needs:
The Lark Sparrow's preference for edge habitats may have excluded it from many research and monitoring efforts. Few studies have focused on this species and its low densities render broad studies less effective. More studies on this species' life history, current range, and habitat requirements are needed.

Oak Titmouse
artwork by Adrienne Olmstead

Oak Titmouse (*Baeolophus inornatus*)

Population:
Given its name, it's no surprise that this species populates many of California's oak and oak-pine woodlands. Usually preferring areas of moderate canopy cover, they nest in natural cavities or holes previously excavated by woodpeckers. While the species continues to appear in every bioregion with oaks in the state, Breeding Bird Surveys indicate a significant decline in California since 1980.

While the Oak Titmouse readily nests near human settlement, and can often seem fearless when faced with human observers, it suffers from the human related invasion of nest-competitors such as European Starlings and House Sparrows.

Management:

Canopy Cover:
The Oak Titmouse prefers woodlands with a canopy cover between 40-70%. Thinning of trees for lumber or firewood cutting may render habitat unsuitable. Land owners and managers should be encouraged to maintain stands with sufficient canopy cover for this species.

Acorn Woodpecker (*Melanerpes formicivorus)*

Acorn Woodpecker
artwork by Adrienne Olmstead

Population:
Of all the birds that rely upon California's oaks, the Acorn Woodpecker is the one most intimately linked to the habitat. With its distinctive clown-like face and "waka-waka" calls, it is easily detectable by most observers and hard to forget once seen. Acorn Woodpeckers breed cooperatively throughout the oak woodlands and oak-pine hillsides of California. They usually live in family groups of 2-15 individuals and cluster around a few granary trees, in which they store acorns. They readily appear on Christmas Bird Counts and Breeding Bird Surveys and can be found both near to and away from human settlements and other disturbance.

The geographic distribution and density of Acorn Woodpeckers in California are significantly correlated with oak species diversity (Bock and Bock 1974, Koenig and Haydock 1999). Reproductive success and population size appear regulated by granary tree availability and the amount of acorns stored during the preceding autumn (Trail 1980; Koenig and Mumme 1987, Stacey and Ligon 1987). Population trend estimates based on Breeding Bird Surveys are inconclusive, though local extirpations due to oak removal have probably occurred and invasion by European Starlings may also pose a threat.

Conservation and Management:

Acorn Harvests:
Acorn Woodpeckers actively harvest and store acorns. Family groups collect acorns and hammer them into drilled holes in granary trees on the territory. This pantry serves to supplement their diet throughout the year, particularly in the winter months when insect prey is sparse. In Arizona, where acorn crops are light, populations do not form family groups and the birds will migrate over the winter to search for food. In California, the fate of Acorn Woodpecker family groups is often closely tied to that of their local oaks; years of low acorn production are often followed by less productive breeding seasons (Trail 1980; Koenig and Mumme 1987; Stacey and Ligon 1987). A reduction in acorn availability, through an overall reduction in oaks, may endanger local populations and groups have been forced to emigrate from an area during years of poor acorn production (Hannon et al. 1987). Managers should seek to maintain large tracts of land to include a natural diversity of oak species or intraspecific oak varieties with different seeding phenologies. This will help avoid synchronous or wide geographic-scale crop failures (Koenig and Haydock 1999).

Granary Trees:
Granary trees anchor Acorn Woodpeckers to a site, providing supplemental food throughout the year. Such trees are often dead or have many dead limbs, which are easier to

bore into. The soft, dead wood is also attractive to fire-wood cutters, whose activities can reduce available habitat for the woodpeckers (Koenig et al. 1995). Managers should encourage the maintenance of all trees used as granaries (trees and limbs filled with tell-tale holes for acorns), even if they are not currently in use by an Acorn Woodpecker group. On average, Acorn Woodpecker groups maintain 2.1 granary trees per 6 ha territory (range 1-7) (MacRoberts and MacRoberts 1976). Land managers should maintain a similar high density of snags and dead tree limbs, or soft-wooded live trees such as pines or sycamores (35 granary trees/100 ha, or 1 snag every 2.86 ha). Dead tree limbs or snags from 17 cm to greater than 100 cm can be used as both a granary and nest site (Hooge 1989).

Grazing and Oak Recruitment:
Damage from cattle grazing in pine-oak woodlands and montane riparian areas may threaten some populations of Acorn Woodpeckers. While Acorn Woodpeckers are still common throughout their range, the low recruitment of new oaks on intensively grazed land will likely not sustain populations in the future. For example, a lack of potential granary trees due to poor recruitment has the potential to cause eventual population declines (Ligon and Stacey 1996).

Land Conversion:
Land conversion from oak woodland to other uses, such as residential or agricultural, can affect woodpecker populations if adequate food resources are compromised. However, Acorn Woodpeckers show a strong ability to adapt to suburban and city-park development if acorns are available. They will often use utility poles and wooden structures, such as sheds and barns, as roosts and granaries (Koenig et al. 1995).

European Starlings:
Starlings often out-compete many native birds for nest cavities. While Acorn Woodpeckers will successfully defend an initiated nest, they usually fail to do so for cavities invaded before nest initiation or egg laying. Starlings are most common near human settlements and their presence can signal of habitat fragmentation. Large tracts of land, away from disturbance, should be maintained whenever possible to discourage invasion of Acorn Woodpecker territories.

Structural and Species Diversity:
Current population levels may rely upon a diverse age structure and species composition of oak trees (Ligon and Stacey 1996, Koenig and Haydock 1999) . Managers can achieve structural and floristic heterogeneity through less intensive grazing methods, planting and protection of multiple species of oak seedlings (using 'tree-pees' etc.), and by creating optimal conditions for oak woodland regeneration.

Western Bluebird (*Sialia mexicana)*

Population:
Western Bluebirds are a common site on fence posts and low snags in oak woodlands and savannas throughout the state. They prefer fairly open areas, though they avoid clear cuts and agricultural fields. Breeding populations of Western Bluebirds appear to be declining in some regions of the state, primarily due to human development and subsequent invasion by European Starlings. Winter populations fluctuate with annual mistletoe crops, and may be excluded from areas where mistletoe, or the oaks it parasitizes, is cleared.

Western Bluebird *photo by Ian Tait*

Management:

Nest box Programs:
Recent efforts to expand nest box building programs may help curtail bluebird declines. Nest box programs should include a monitoring component which:

1. Ensures that boxes are being used by native species. Those that are not should be reviewed and perhaps removed to avoid use by unwanted species such as House Sparrows or European Starlings.
2. Ensures that predators are not regularly taking nestlings or killing adults.
3. Maintains boxes in good condition. For example, woodpeckers will enlarge holes that will allow predators, especially European Starlings and House Sparrows, to get into nest boxes and destroy nests.

You can find guidelines from the **North American Bluebird Society** on-line at http://www.nabluebirdsociety.org/.

Logging Practices:
The practice of "thinning" is less detrimental to bluebirds than "clearcutting." This problem is particularly relevant in areas where oaks are cleared to install vineyards or conifers (for logging). Leaving at least some oaks may mitigate these losses. Bluebirds, like many cavity nesters, require older trees with naturally occuring or previously excavated cavities. Furthermore, they prefer live trees rather than ones that have completely died.

Urbanization:
This problem extends to all animals reliant on oak woodlands. Increased urbanization leads to the introduction of nest-site competitors and predators such as House Sparrows, European Starlings, and an increase of mammals associated with urban areas (such as cats, skunks, and raccoons).

Blue-gray Gnatcatcher (*Polioptila caerulea*)

Population:

Blue-gray Gnatcatcher at nest *photo by Ian Tait*

Blue-gray Gnatcatchers historically bred in oaks and chaparral stands throughout most of California's bioregions. Data from the past thirty years show some declines and extirpations, possibly connected with the expansion of Brown-headed Cowbirds and the heavy parasitism gnatcatchers incur. There have been no recent surveys that adequately estimate their current breeding range. Where nests have been found, nest success is extremely low and parasitism common, a characteristic shared with other gnatcatcher species, including California and Black-tailed, signaling a need to gather more conclusive information about the California population.

Management:

Brown-headed Cowbirds:

Until recently, Blue-gray Gnatcatchers appeared extirpated from San Diego County, probably due to overwhelming parasitism pressures. Conservation efforts on behalf of the Least Bell's Vireo and California Gnatcatchers may benefit Blue-gray Gnatcatchers in the region. Monitoring of the two listed species should be extended to include Blue-grays to establish whether their population is expanding with control efforts as well.

Diverse Habitat Structure:

Blue-gray Gnatcatchers prefer to nest in open scrubby areas and forage in more dense vegetation. Protected and managed habitat should maintain such diverse structure, including mosaics of oaks and shrubs.

Research and Monitoring:

Few recent data are available for Blue-gray Gnatcatchers in California. Breeding Bird Surveys and Point Counts poorly sample populations because these birds live in relatively low densities, though they are easily recognized when found. Breeding Bird Atlas data may provide valuable insight to local population changes. However, much more detailed study is needed. The few nest studies that do include Blue-gray Gnatcatchers demonstrate an extremely low nest success rate.

Population Targets

Partners in Flight seeks to develop avian population targets that will guide conservation efforts and provide land managers with a gauge of success for their restoration and management activities. Although ambiguous and hard to develop, numerical population targets provide a compelling means of communicating with the public and policy makers. In some cases, targets may simply require maintenance of populations at existing levels. However, targets for rare or declining species will encourage actions that increase existing populations to sustainable levels.

Bioregionally-based population targets for many of the primary and secondary oak woodland species have been developed using all available data (Table 5-1). These targets are simply the highest densities (either indirectly through point counts, or directly through spot mapping) found for that species within a given bioregion. These data are currently lacking from most bioregions and for many species. More data likely exist for some of these species, and contributions of data to CalPIF is encouraged for incorporation into future versions of this "living" document.

Two types of data are presented. The first is spot map data, in which the number of territories per 40 hectares is estimated based on Breeding Bird Census plots (plots are usually less than 40 hectares, but are converted for purposes of standardization). The second is point count data, in which the average number of individuals detected within 50 meters of a point count station is presented. These two types of data are not necessarily comparable to one another, nor convertible. Such reference density estimates are useful as population density targets that can translate into habitat acreage protection for some species, or be considered in restoration goals.

Table 5-1. Suggested population targets by species and bioregion[1]. See Table 5-2 for a key to data sources, indicated here by superscripts [A-K].

Species	Bay-Delta		South Coast		Sierra		San Joaquin		Central Coast	
	Point Count[A]	Spot Map	Point Count	Spot Map[C]	Point Count[D]	Spot Map	Point Count	Spot Map	Point Count	Spot Map

Bewick's Wren	0.46	-	-	2.5	0.23	9.2[F]	-	-	-	23.3[H]
Blue-gray Gnatcatcher	0.10	-	-	2.5	0.27	10.0[A]	-	-	-	23.3[H]
Hutton's Vireo	0.19	15.6[B]	-	7.5	0.01	1.4[E]			-	3.3[I]
Lark Sparrow	-	-	-	-	0.39	0.5[E]	-	-	-	2.3[I]
Lewis' Woodpecker	-	-	0	0	-	-[3]	?	?	-	-
Nuttall's Woodpecker	-	-	-	-	0.09	1.6[E]	-	-	-	2.3[H]
Oak Titmouse	0.40	15.4[L]	-	35	1.33	26.4[E]	-	-	-	49.4[I]
Western Bluebird	-	-	-	-	0.38	5.0[A]	-	-	-	8.2[H]
Western Scrub-Jay[2]	0.61	-	-	-	0.31	10.9[F]	-	-	-	7.0[H]
White-breasted Nuthatch	-	-	-	-	0.82	4.3[E]	-	-	-	10.2[I]
Yellow-billed Magpie	-	-	0	0	-	-	-	-	-	-

[1]Numbers provided from point counts are the average number of detections within 50 meters (*n* / # points / # visits) of the observer during five minute counts during the breeding season. Point count data provide an index of abundance, generally thought to be conservative. Numbers from spot mapping are pairs per 40 hectares during the breeding season, unless otherwise noted. *Reference populations are cited and may not be representative of healthy populations.* Dashes represent no data and zeroes indicate the species probably never bred in that bioregion.

[2]Not an appropriate species to set population targets according to high counts/ high breeding densities, due to implications for other species.

[3]No Lewis' Woodpeckers have been found nesting at San Joaquin Experimental Range[E,F] during a long-term nest searching effort, although they are abundant winter residents (K. Purcell, personal communication).

Table 5-1 (cont.).[1]

[2]Not an appropriate species to set population targets according to high counts/ high breeding densities, due to implications for other species.
[3]Additional data on territory densities can be found in Wilson et al. 1991 for Mendocino County.

Table 5-2. Sources of population data in Table 5-1.

Alpha code	Data source, habitat type, location, and year.
A	PRBO unpublished data. Bay-Delta data are from Marin Co. (Holmes et al. 1998) except for Oak Titmouse, which are from the Cosumnes River Preserve, Sacramento Co. Sierra data are from Independence Creek, mixed black oak and riparian habitat (1999 for Blue-gray Gnatcatchers, 2000 for Western Bluebird).
B	Van Fleet 1919; live oak woodland.
C	May and Peters 1979; coast live and Engelmann oak woodlands, Orange Co.,1978.
D	PRBO unpublished data; Tehama Co. foothills, 2001.
E	Verner et al. 1997; grazed oak woodland, San Joaquin Experimental Range, Madera co., averaged over nine years (1985-1993).
F	Verner et al. 1997; ungrazed oak woodland, San Joaquin Experimental Range, Madera co., averaged over nine years (1985-1993).
G	MacRoberts and MacRoberts 1976; Hastings Reservation, Monterey Co., territory density based on average territory size of 6 ha (average number of adults per territory = 4.4; Koenig et al. 1995).
H	Williams 1979, 1980, Joste 1981; blue oak woodlands, Monterey Co., averaged over three years 1978-1980.
I	Tietje et al. 1997b, Camp Roberts, San Luis Obispo Co., averaged over two years (1994-1995).
J	PRBO unpublished data. Klamath data are from Brewer's Oak forests in the Mendocino National Forest, Mendocino Co (1996); Sacramento Valley data are from blue oak forests at East Park Reservoir, Colusa Co.
K	Gaines 1979; blue and interior live oak woodlands, Sutter Co.
L	Cicero 2000; San Francisco Bay region, based on average territory size of 2.6 ha.

Chapter 6. Bioregional Conservation Objectives

California has a higher biodiversity of wildlife and plants than any comparable area in the northern temperate zone (Biosystems Analysis 1994). The state also has more endemic species, particularly plants and birds, than any other state except Hawaii. This great diversity provides significant challenges in conservation planning, particularly over a state as large and geographically diverse as California.

As with the other habitat plans, we have adopted the California Biodiversity Council's 10 bioregions as a guideline for dividing the geography of California into natural communities organized by biota, climate, topography and soils (RAC 1998). See Figure 3.1 for bioregion boundaries. These contrast slightly with the 11 discrete regions recognized by Sawyer and Keeler-Wolf (1995) and Biosystems Analysis (1994).

Setting conservation goals by bioregion helps facilitate planning site-specific projects in a broader context, and provides a similar framework to other conservation planning efforts. Setting and achieving conservation goals by bioregion will:

- Ensure that a suite of ecological communities representative of California's diversity will be conserved throughout the state.
- Ensure that the broadest range of biodiversity and locally adapted races of species will be conserved.
- Facilitate action at the local level.

This section introduces each of the 10 bioregions considered in this plan. These descriptions are offered as an overview; the issues and needs may vary depending on particular sites within a bioregion. For more information on each, please consult the Resource Agency of California's *Preserving California's Natural Heritage* (RAC 1998).

For each bioregion, we list potential "Portfolio Sites", areas that are distinguished by their protected status and potential for managing oak woodland habitat through restoration. Many of these Portfolio Sites contain oak woodland habitat located near other habitats of concern. Thus, there is considerable potential for management of such areas to achieve goals for the many CalPIF habitat plans. This list is not comprehensive and will be updated as the Plan is revised. These sites have been identified by our own experience in oak woodland habitat and by drawing from the excellent volume by Pavlik et al. (1991). We ask that individuals and groups working in these bioregions bring important sites and activities to our attention.

It is important to make a distinction between our use of the term "Portfolio Site" and its use by other organizations. Most notably, The Nature Conservancy of California has identified a list of sites which are prime candidates for conservation and which are ranked in order of priority based on their biological richness and the immediacy of threats to them. Some of these sites are also considered as Portfolio Sites in this and other CalPIF Bird Conservation Plans, and more may be included in the future as they become protected and efforts to manage for oak woodland are expanded.

Sacramento Valley

The northern portion of the Central Valley, the Sacramento Valley is a region characterized by hot, dry summers, and cool, foggy winters. The great Central Valley of California is a region that has undergone considerable transformation in the past century, from a mosaic of wetlands, riparian forests and dry grasslands containing millions of waterfowl, elk, pronghorn and other wildlife (an "American Serengeti"), to a virtual agricultural machine. Nonetheless, in the uplands that surround the valley floor and in localized bottomlands there remain several areas important to oak woodland habitat. These upland areas are among the many regions in California where conversion of habitat to vineyards poses a serious threat to oak woodlands. The lowland areas include areas that are or historically were valley oak woodland and have been degraded or reduced through development, agriculture, and the damming of California's rivers.

Portfolio Sites

East Park is a Bureau of Reclamation (BOR) site of oak woodland and riparian habitat surrounding the East Park Reservoir, in the foothills of the Coast Range near the town of Maxwell. Extensive blue oak woodland is found here along with few, but large, valley oaks. BOR is interested in managing this area for wildlife. There is good potential for management beneficial to oak woodland habitat, which would be crucial for supporting recruitment in both valley and blue oaks.

East Park, Sacramento Valley Portfolio Site *photo by Geoff Geupel, PRBO*

Bidwell Park has many acres for valley oak (2,250 acres) woodland in Northern California. The ownership is the City of Chico, Parks and Recreation, and it is the second largest municipal park in the country.

The Sacramento River region now includes areas under intensive restoration. Efforts are underway to re-establish valley oak (Alpert et al. 1999). Partners include the Nature Conservancy, the U.S. Fish and Wildlife Service, the California Department of Fish and Game, and the California Wildlife Conservation Board and stakeholders participating in the Sacramento River Conservation Area. This area is also a Portfolio site in the Riparian Bird Conservation Plan.

Cache Creek is an important area in northern California with large stands of both valley and blue oak. This land is administered by BLM, and has potential for restoration of recruitment and regeneration of these imperiled trees.

San Joaquin Valley

Also a major part of California's Central Valley, the San Joaquin Valley has been thoroughly transformed by intensive agriculture and development. Another industry important to the region's economy has been oil. The region is characterized by similar weather to the Sacramento Valley, including hot, dry summers and cool, foggy winters. Along with the rest of the wetlands, native grasslands and riparian vegetation, the valley oak riparian forests once characteristic of this region are almost gone (Bolsinger 1988). The water flow and habitat along the San Joaquin River itself, for instance, has been significantly diminished by the development of agriculture or mining along nearly every mile of its reach and by the construction of the Friant Dam (RHJV 2000). Nonetheless, crucial remnant pockets of valley oaks remain. Additionally, some upland areas containing oak woodland habitats exist in the foothills of the surrounding mountain ranges, including regions where conversion to wine vineyards has occurred or continues.

San Joaquin Valley *photo by Geoff Geupel, PRBO*

Portfolio Sites

Kaweah Oaks Preserve has one of the last valley oak riparian forests remaining in the region. This 324-acre preserve, owned originally by The Nature Conservancy and now by the Sierra Los Tulares Land Trust, is a private wildlife sanctuary created for the purpose of protecting valley oaks and associated wildlife. Valley oak regeneration has taken place (as well as many other native vegetation changes) since cattle were removed.

Caswell Memorial State Park also protects one of the last remnant valley oak riparian forests in the San Joaquin Valley. These 258 acres located northwest of Modesto have been owned and managed by the California state parks system since the 1950's. CalPIF and other organizations have documented the high use and clear importance of this small park to birds.

Oak Grove Regional Park is the site of a cattle ranch where valley oaks were retained (Pavlik et al. 1991). Today, this 170-acre park located near the city of Stockton is managed by the San Joaquin County Department of Parks and Recreation.

Modoc

Of all the California bioregions, perhaps Modoc most resembles its historic state. It is host to the least number of human inhabitants of all ten bioregions, but continued human growth is likely as pressures increase along with California's population expansion. The landscape is characterized by extensively forested mountains, vast reaches of high desert, and volcanic uplands. Typical weather includes hot dry summers and cold, wet winters, with snow at higher altitudes. Oak woodlands are sparse and few, with black oak most common and Oregon oak also present. As in other montane habitats, changes in the fire cycle, due to fire suppression and increased fuel accumulation, has had an impact on the structure and ecology of hardwood forests in this bioregion.

Portfolio Sites

Quail Spring is identified as an area where black oak co-occurs in mixed conifer stands (Pavlik et al. 1991). It is located east of MacArthur on Highway 299 and managed by the Modoc National Forest.

Klamath

The Klamath region is home to some of the most dramatic geologic landscapes on earth. It is known for its steep, rocky shorelines, rich coniferous forests of coast redwoods and Douglas firs, extensive mountain ranges and salmon runs. No other bioregion in California receives as much rainfall, and the bioregion is characterized by cool, foggy summers along the coast and rainy winters throughout. Its high mountains create a dramatic rain shadow, resulting in stark contrast between the north coast climate and the nearby interior. Ranges in this mountainous region include the Klamath, Siskiyou, Marble, Salmon, Trinity, and Cascade Mountains, and the North Coast Range.

The bioregion is home to five national forests, the Siskiyou, Six Rivers, Klamath, Shasta-Trinity, and Mendocino. Also in this region is Redwood National Park, a network of state parks and wilderness areas, Jackson State Forest, as well as forests on private land (such as the well-known Headwaters redwood forest in Humboldt County). Although the region has received much attention for its ancient redwood forests, some areas also contain extensive tanoak forests. The northernmost detection of tanoaks infected with Sudden Oak Death (SOD) were found in the Klamath bioregion.

Portfolio Sites

Redwood National Park is known for redwoods, of course, but also contains extensive tanoak forests. To date these tanoaks are not infected with the pathogen causing Sudden Oak Death (SOD). Oregon oak, black oak, and canyon oak occur on the drier slopes and bottomlands.

Humboldt Redwoods State Park also contains stands of tanoaks. This was the furthest north location that SOD was detected in 2000, with 11% of the tanoaks infected.

Hopland Field Station on the Russian River is engaged in active efforts at oak regeneration (Pavlik et al. 1991). This University of California field station is a site of active research on oak woodland issues (see Merenlender and Crawford 1998; Merenlender et al. 1998).

McLaughlin Reserve is a recent addition to the UC Davis Natural Reserve System and is located in the inner North Coast Range, at the junction of Napa, Lake and Yolo Counties, on land owned by the Homestake Mining Company. The 2,800 ha (7,050 acre) site, of which 20 % is oak woodland, is in transition: the Homestake gold mine is in its last phases of operation, and the McLaughlin Reserve is beginning to be used for teaching and research. It is surrounded by some 30,000 hectares (75,000 acres) of land managed by the US Bureau of Land Management (BLM).

The Northern California Coast Range Preserve is an immense region (7,800 acres) managed jointly by The Nature Conservancy and the University of California. Oak habitats include tanoak, black oak, Oregon oak and others. SOD infection occurs in populations of tanoak and black oak. If SOD continues to expand, this region would be important in understanding how to manage the acorn production of other oak species as tanoaks and black oaks decline.

Central Coast

California's Central Coast is characterized by a mild climate, beautiful coastline, small mountain ranges that roughly parallel the coastline, and a wide variety of habitat types. The favorable climate in this region supports a robust agricultural industry that includes vineyards, row crops and grazing.

In recent years, the Central Coast has undergone a dramatic population increase, fueled largely by prosperous industries such as Silicon Valley's booming computer industry. This sudden and expansive growth threatens the region's habitats through land conversion, water

diversion, logging, resource extraction, grazing, and habitat clearing. Some of the worst effects of SOD are visible on the coastal forests in this region, predominantly affecting tanoak and coast live oak, and occasionally black oak.

Portfolio Sites

Hunter-Ligget Military Reservation is an extensive area where considerable research has been conducted on oak woodland ecology and prescribed fires (Tietje et al. 1997). This reservation may be an important area for various management ideas on the SOD epidemic and other oak woodland issues to be implemented and explored.

Hunter-Ligget Military Reservation *photo by Sandy Scoggin, PRBO*

Pfeiffer Big Sur State Park contains 800 acres of oaks and other forested habitats. Of all the sites monitored in 2000, this was one of the hardest hit by SOD. Nearly 90% of tanoaks and more than half of other oak species (coast live oak, interior live oak and black oak) were dead or dying. Understanding how the acorn-dependent bird community copes with such devastation over the next few years will be crucial.

Henry Cowell Redwood State Park is located within the Santa Cruz Mountains and is home to a number of forest habitats, including tanoak, coast live oak, redwood, ponderosa pine, madrone and Douglas-fir. It is another area hit particularly hard by SOD. Some 47% of the tanoaks here were dead or dying in 2000.

Hastings Natural History Reservation is located in the foothills of the Santa Lucia Mountains in Monterey County. Its 2000 acres are administered by the Museum of Vertebrate Zoology at the University of California, Berkeley as part of the UC Natural Reserve System. Oak woodlands dominate the landscape, including valley and blue oak hillsides as well as live oak and mixed hardwood forests. The reserve is a biological field station containing numerous long-term data sets pertaining to the natural history and population biology of native species in these oak woodland habitats. It is a prime area for conducting research on the region's wildlife and ecology. Bird data sets it is renowned for include the long-term study of Acorn Woodpeckers and of Western Bluebirds.

Sedgewick Reserve is a UC Natural Reserve administered by UC Santa Barbara. Encompassing 2,382 hectares (5,883 acres) in the Santa Ynez Valley, the reserve in includes

several types of oak woodland habitats: coast live oak forest, blue oak woodland, and valley oak savannah. The site is home to several studies on oak ecology and the factors influencing oak regeneration.

Bay-Delta

The Bay Area-Delta Bioregion includes the San Francisco Bay area and spreads eastward to encompass the sprawling Sacramento-San Joaquin River Delta. The climate is relatively mild, with fog on the coast, warm summers inland, and wet winters. The pressure for development in this very populous region is high. This area is host to a great variety of habitat types and associated avifauna. In fact few areas in the country have such a mix of dense population centers amongst a fairly diverse wildlife setting. It is in this region that SOD was first discovered in 1995. The vineyard industry is also booming in this region.

Portfolio Sites

Marin Municipal Water District is an area containing many habitats, including tanoaks, black oaks and coast live oaks. Many of these forests are also infected with SOD. Because the Point Reyes Bird Observatory conducted extensive point counts in the watershed before the emergence of SOD in this region, there is a unique opportunity for evaluating the effect on the bird community of this epidemic as it progresses, particularly those species dependent on acorns. Researchers from the University of California (Don Dahlsten and Bill Tietje) are also studying the impact of SOD on birds and other small vertebrates in this area.

Point Reyes National Seashore and the Golden Gate National Recreation Area are also areas in Marin County that are host to very diverse habitats, including those where oaks are present or predominant. These lands are owned and managed by the National Park Service. Many of these forests are also infected with SOD. The Point Reyes Bird Observatory also conducted extensive point counts in all habitat types within these parks before the emergence of SOD in this region.

China Camp State Park, located on the San Pablo and San Francisco Bays, is another site of extensive research on the new SOD problem. Coast live oak and black oak are dead and dying here. Valley oak nearby is, to date, unaffected.

Cosumnes River Preserve contains one of the finest stands of valley oak forests remaining in the Central Valley. This nature preserve is cooperatively owned and managed by The Nature Conservancy, Ducks Unlimited, U.S. Bureau of Land Management, California Department of Fish and Game, Department of Water Resources, and Sacramento County Department of Parks and Recreation. An ambitious regeneration project has been implemented (Pavlik et al. 1991).

The **Mount Hamilton** Region is an extensive open space in the central Diablo coastal range south and east of San Jose. The area contains extensive public lands, including the

Sunol Regional Wilderness and the **Henry Coe State Park**. The Nature Conservancy is building on this basis by securing the permanent protection of key private properties that surround and connect the public lands. This provides a rare opportunity to manage for oak woodland viability on a landscape scale.

South Coast

The South Coast Bioregion includes miles of sandy beaches and steep cliffs along the coast, small mountain ranges, and extensive conifer and scrub habitats. The climate is arid and warm throughout the year. The human population is very large and continues to expand rapidly, converting and fragmenting native landscapes at an alarming rate. Much land falls under the jurisdiction of forest service (Angeles, Los Padres, Cleveland, and San Bernardino National Forests), state and local parks, state beaches, and federal wilderness, recreation areas and wildlife areas. The Channel Islands off the coast of Los Angeles contain several endangered endemic species of California, including island oak. Island oak is the rarest of all oak tree species in California.

Portfolio Sites

Santa Cruz Island Preserve, managed by The Nature Conservancy, contains numerous stands of island oak and at least seven other oak species (Pavlik et al. 1991). The ongoing removal of feral ungulates (goats, sheep, and pigs) will hopefully provide opportunities to manage and restore regeneration in this key species.

Santa Rosa Plateau Ecological Reserve, a 8,300 acre Nature Conservancy property in Riverside County, is an important reserve for Engelmann Oak savannah habitat.

The **Nature Reserve of Orange County**, although perhaps better known for its coastal sage scrub habitat, also contains oak woodlands and is the site of a demographic bird monitoring project. This 38,000-acre reserve combines 21,000 acres of Irvine Company land with 17,000 acres of county and state parks, as well as other public and private lands

Mojave and Colorado Desert

These regions are dominated by the expansive deserts of southeastern California. Climate is characterized by hot, dry summers and fairly cold winters. Few people inhabit this bioregion, but it is already growing as population pressures in the rest of the state increase. Oak woodland is very sparse in these regions (less than a 10^{th} of a percent of the total area) but small pockets do exist, including blue oak woodland, oak/pine foothill, and black oak habitats.

Sierra

The Sierra Bioregion spans a vast and mountainous area, characterized primarily by the extensive and rugged Sierra Mountains and the arid eastern portion of the state. It is a region rich in biodiversity, containing over half the plant species found in California and more than 400 of the state's terrestrial wildlife species (RAC 1998). Evidence suggests that many of the region's more common birds may be in decline (Siegel and DeSante 1999). In the montane regions this area is the key domain for black oak in California, and blue oak

woodland and blue oak/foothill pine habitats are found in the foothills. The booming vineyard industry certainly extends into and threatens these blue oak habitats of the Sierra Bioregion. While almost all of the blue oak woodlands in this region are on private land (SNF 2000), the majority of the Sierra Bioregion lands are managed by public agencies, and much of the black oak forests are in national forests. Resource managers and landowners appear willing to invest time and money into finding more ecologically sound management practices and are incorporating conservation recommendations into work plans and project goals (Siegel and DeSante 1999, SNF 2000).

An extensive review of the conservation needs and recommendations for much of this region has been provided in the Avian Conservation Plan for the Sierra Nevada Bioregion (Siegel and DeSante 1999), the Sierra Nevada Ecosystem Project (Davis and Stoms 1996), and the Sierra Nevada Framework (SNF 2000). The Sierra Nevada Framework summarizes the history, ecology and conservation issues in Sierran oak (and other) habitats, and recommends management alternatives to be implemented in national forests of this region (www.r5.fs.fed.us/sncf).

Portfolio Sites

San Joaquin Experimental Range is a USDA Forest Service research facility located in the foothills of Madera county. The oldest rangeland research station in California, its 1875 hectares (4600 acres) consist of blue oak/foothill pine woodlands and annual grasslands. The site has a long history of research and education on oak ecology, wildlife, range management, water quality, and other aspects of the ecosystem. It also contains one of the longest-running bird monitoring efforts in California oak woodlands (Verner et al 1997, Purcell et al. in press). Currently SJER is managed by California State University Fresno, under a long-term agreement with the USDA Forest Service, Pacific Southwest Research Station.

Yosemite Valley, in Yosemite National Park, is undergoing extensive restoration of once-extensive black oak woodlands (Pavlik et al. 1991).

The **Lassen Foothills** region is an extensive area of grasslands and Blue Oak woodlands. The Nature Conservancy is working to protect this area from fragmentation by promoting conservation easements and acquiring land. Two preserves here run demonstration projects that include habitat restoration, rotational grazing, prescribed burning, and other range management techniques with potential to benefit oak woodlands.

Chapter 7. Implementation of Conservation Plan Recommendations

An implementation strategy for the Oak Woodland Bird Conservation Plan is in development. It will include the engagement of local, bioregional conservation efforts to better define bioregional priorities for acquisition, restoration, and focused conservation efforts. The implementation process will eventually include a series of local workshops to:

- Familiarize local organizations with the Conservation Plan and the Implementation Plan
- Identify local initiatives, projects, and organizations capable of working as local partners to achieve habitat, restoration, and population targets.
- Develop conservation and restoration acreage objectives based on inventory, assessment and biological need.

The North American Bird Conservation Initiative

Yellow-billed Magpie
artwork by Adrienne Olmstead

In 1998, participants at a meeting of the International Association of Fish and Wildlife Agencies developed a vision to link all of the major bird conservation initiatives in Canada, the U.S. and Mexico (CEC 1998). The participants represented each of the four major bird conservation initiatives already underway on the continent: The North American Waterfowl Management Plan (the oldest and most successful of bird conservation initiatives), Partners in Flight, the Shorebird Conservation Plan, and the Colonial Waterbird Conservation Plan. This new overarching program, known as the North American All Bird Conservation Initiative (NABCI), seeks to synthesize the efforts of all these groups by creating "regionally based, biologically driven, landscape-oriented partnerships delivering the full spectrum of bird conservation across the entirety of the North American continent, including simultaneous, on-the-ground delivery of conservation for both game and nongame birds." See www.nabci-us.org for more information.

State, provincial, federal and non-governmental representatives from Canada, Mexico, and the U.S. adopted an ecological framework that facilitates coordinated conservation planning,

implementation, and evaluation among major bird initiatives. These Bird Conservation Regions (BCRs) were defined by adopting the hierarchical framework of nested ecological units delineated by the Commission for Environmental Cooperation (CEC).

Existing joint ventures as formed under the North American Waterfowl Management Plan (NAWMP) are recognized as important vehicles for local and regional delivery of bird conservation goals. Joint venture focus areas do not always correspond with BCR boundaries, but joint ventures are coordinating with the BCRs encompassed within their boundaries. Many joint ventures in North America have embraced the concept of "all-bird" conservation.

California is encompassed within five BCRs: the Northwestern Pacific Rainforest region, the Sierra Nevada region, the Coastal California region (which includes the Central Valley), the Great Basin region, and the Sonoran and Mohave Deserts region. The state currently hosts five Joint Ventures: the Central Valley Habitat Joint Venture, the San Francisco Bay Joint Venture, and the Riparian Habitat Joint Venture (all located entirely within the state), and the Intermountain West Joint Venture and the Pacific Coast Joint Venture (both located partially within the state). Future bird conservation in priority habitats of California will be achieved by encouraging adoption of the all-bird conservation concept within existing joint ventures of the North American Waterfowl Management Plan and/or by expansion of the Riparian Habitat Joint Venture to include other habitat types.

The following is only a partial list of programs and agencies with which CalPIF intends to interface in implementing this plan:

Non-governmental Organizations:
American Farmland Trust
California Oak Foundation
California Native Grass Association
California Native Plant Society
California Farm Bureau Federation
Cosumnes River Project
California Cattleman's Association
Solano Farmlands and Open Space Foundation
Point Reyes Bird Observatory
Wildlife Conservation Society
National Audubon Society
National Fish and Wildlife Foundation
The Nature Conservancy
Wildlife Conservation Society

Private Organizations:
Hedgerow Farms
California North Coast Grape Growers Association
Wine Institute
Napa Valley Vintners Association
Sonoma County Vintners and Growers Association
Carneros Quality Alliance

Certified Rangeland Managers
Registered Professional Foresters

University Organizations:
University of California Integrated Hardwood Range Management Program
University of California Cooperative Extension (UC-Berkeley, UC-Davis)

State of California Organizations:
California Department of Fish and Game
California Department of Forestry and Fire Protection
Sonoma County Agricultural Preservation and Open Space District
Resource Conservation Districts (many occurring in the range of oak woodlands)
State Park System in California
Wildlife Conservation Board

Federal Organizations:
USDA Forest Service
US Fish and Wildlife Service
Bureau of Land Management
Natural Resource Conservation Service
Bureau of Reclamation

Chapter 8. Conservation Action Recommendations

Specific recommendations for conservation action are offered here. Each recommendation is accompanied by a brief discussion of the scientific evidence that supports it. These recommendations cover actions in several areas:

- habitat protection and restoration
- land management
- monitoring and research
- policy

Many of these recommendations follow those made by other organizations, or complement them. The goal of these recommended actions is to facilitate the protection and restoration of oak woodland habitat, including the successful recruitment of new oaks for future generations of the wildlife that depend on them. Only by restoring the processes involved in oak regeneration can oak woodland birds be secured a future, and thus avoid their listing as threatened or endangered species. Likewise, restoring oak regeneration will contribute to preserving sustainable working landscapes. It is our hope that these recommendations will help galvanize and guide the programs of conservation organizations, expenditures of government agencies, and the actions of private and public land managers.

Most recommendations are supported by the most recent scientific data and analysis available and a synthesis of ecological literature on oak woodlands. Additionally, recommendations were derived from focal species accounts (see http://www.prbo.org/calpif/). Some recommendations are, as of yet, poorly supported by data, but can be evaluated through biological research, monitoring, and adaptive management. This process will allow the continuing refinement of these recommendations and the development of more effective management and restoration strategies.

Habitat Protection Recommendations

OBJECTIVE 1

Prioritize oak woodland sites for protection.

Recommendations

1.1. Prioritize sites with intact oak regeneration and decay processes.

One of the greatest threats to oak woodland habitat in California is the lack of oak regeneration, specifically in blue, interior live, Oregon white, and valley oak communities. Habitats that presently harbor healthy bird populations will fail to support future generations of oak woodland-associated bird species if regenerative processes are not intact.

Regeneration may be considered to be adequate if the number of seedling and sapling oaks is sufficient to offset mortality (Standiford and Tinnin 1996). Oak recruitment may be episodic, and therefore sites that currently lack young oaks may still be viable in the future. However, prioritizing sites that are presently demonstrating healthy oak regeneration constitutes a step towards insuring viable habitat for future bird populations.

Other important parts of an ecologically functioning oak woodland system are acorn production and oak tree decay. Four oak woodland-associated species, Acorn Woodpecker, Yellow-billed Magpie, White-breasted Nuthatch and Western Scrub-Jay, depend on acorn production as a food source and in turn, are instrumental in the dispersal process needed for oak regeneration. Ten of the oak woodland-associated focal species depend on decaying trees and limbs for nest cavities and also, in the case of Acorn Woodpecker, Oak Titmouse and White-breasted Nuthatch, for storing food.

1.2. Prioritize sites according to current indicators of avian population health.

Conservation efforts should use the most recent information regarding the present quality of habitat and wildlife populations to prioritize the acquisition and protection of sites. Although it is unknown whether demographic bird monitoring data can predict the regenerative potential of oak woodland habitats, they do provide a means to prioritize habitat quality in its present condition.

1.3. Prioritize sites to include diverse age structure of oak trees, especially large old oak trees.

Protecting sites with a diverse age structure of oak trees will provide a continuum of seeding phenologies, preventing synchronous or wide-scale acorn crop failures. Maintaining large old oaks within a diverse age structure will provide decaying limbs necessary for bird nesting sites in addition to high output acorn production. McDonald (1990) demonstrated that Black Oaks much reach 30 years before producing viable acorns and seldom produce large quantities of acorns until they reach 80-100 years. Good acorn producing trees can continue abundant production up to 200 years.

Territorial requirements for the Acorn Woodpecker, a species instrumental in acorn dispersal, include large central trees for nesting, granary and roosting, surrounded by a periphery of smaller or medium sized trees.

1.4. Prioritize sites to represent a diversity of oak woodland types.

The full range of variation in oak woodland habitat types (and associated animal species) can be protected by: 1) protecting a diverse portfolio of sites located in different parts of the geographic and elevation range of oak woodlands, and 2) protecting individual sites that contain a variety of oak woodland types. Protecting the variety of oak woodland types may help protect the various birds that are associated with different types of oak woodland habitats. For example, Lark Sparrows are likely to be found more often in open, savanna-like oak habitats (Small 1994), while Dark-eyed Juncos may be more abundant in denser

woodlands with a thick understory (Tietje et al. 1997). Some bird species also appear to occur in higher numbers when the diversity of oak woodland types present in the surrounding landscape is higher (Stralberg and Williams, 2002).

1.5. Prioritize sites according to surrounding land use.

Certain uses of land adjacent to oak woodland habitat may negatively impact the quality of that habitat for native birds. For example, oak woodlands that are adjacent to pastures or residential developments may be more accessible to European Starlings, which compete for nest cavities with other secondary cavity nesters (Verner et al. 1997, Merenlender et al. 1998). Urban or suburban development may also have a negative effect on the presence or abundance of some bird species, including Lark Sparrow and Rufous-crowned Sparrow, in adjacent oak woodlands (Stralberg and Williams, 2002).

1.6. Prioritize oak woodland sites adjacent to intact chaparral, grassland, pine or and riparian habitats.

Riparian areas are especially important to many species of birds and other wildlife that are also found in adjacent oak woodlands (RHJV 2000). An analysis using the California Wildlife Habitat relationships System (CWHR) predicted that 150 species of birds use riparian habitat within or adjacent to oak woodlands for breeding, feeding and/or cover (see Chapter 4 in Standiford and Tinnin 1996). Many birds that are more typical of chaparral or grassland habitats can also be found in adjacent oak woodlands. Thus, the bird community found within oak woodland patches is strongly influenced by the type of habitat that surrounds them (Sisk et al. 1997).

1.7. Prioritize sites according to landscape variables (patch size, shape, connectivity) that adequately support the desired populations of oak woodland-dependent species.

Large, unfragmented, and connected areas of oak woodland should have high priority for protection, for a number of reasons. Bird species composition can be altered by habitat fragmentation. For example, the proportion of neotropical migrant species in the bird community was found to be higher in undeveloped oak woodland than in ranchette developments (Merenlender et al. 1998). The same study found a number of bird species to be more abundant in subdivided oak woodlands. These include Western Scrub-Jay, a common predator on the nests of other birds, and European Starling, an exotic competitor of cavity nesting birds (Purcell and Verner 1999). Stralberg and Williams (2002) found several bird species, mostly neotropical and short distance migrants, to increase in abundance with the proportion of oak woodland habitat remaining in the surrounding landscape.

1.8. Prioritize sites according to management options.

Sites in which management can be used to restore natural ecosystem processes should be given a high priority for protection. For example, sites in which a natural fire regime can be

re-established might be assigned a higher priority than sites in which there is a need for strong fire suppression. Sites in which the impacts of grazing can be strictly managed may also be priorities for protection.

1.9. Prioritize sites based on conservation threats and opportunities for protection.

The above guidelines are useful for identifying the highest quality oak woodland sites in the state, however, not all of these sites will be equally threatened by imminent habitat loss and degradation. Therefore, an analysis of impending threats and conservation funding potential should be included in the prioritization process. Habitat quality, vulnerability, and conservation potential all must be considered in designing the best conservation strategies.

OBJECTIVE 2

Increase acreage of protected oak woodland.

Using the above prioritization guidelines, a variety of preservation tools should be applied to increase the acreage of oak woodland in California that is managed for birds and other wildlife. These tools include: conservation easements, fee ownership of preserves, partnerships between government agencies and nonprofits, sustainable forestry and ranching, and woodland grass banking. Future versions of this plan should contain quantitative goals for oak woodland protection.

Habitat Restoration Recommendations

OBJECTIVE 3

Prioritize oak woodland sites for restoration.

Recommendations

3.1. Prioritize restoration sites according to their proximity to existing high quality sites.

Restoration sites may be more likely to be colonized by oak woodland birds if they are close to areas of high quality habitat that can serve as sources of immigrants. Dispersal distances of oak woodland birds are largely unknown, with one exception: Acorn Woodpeckers have been shown to dispersal relatively long distances (Koenig et al. 2000). However, many of the smaller, resident bird species in oak woodlands may have relatively restricted dispersal ability. If so, bird populations may be more likely to be reestablished and to persist in restoration sites that are close to areas of high quality habitat that can serve as sources of immigrants. Further research is needed to evaluate the influence of habitat isolation on oak woodland birds.

3.2. Prioritize restoration sites according to likely success of regeneration and transplanted oak viability.

Restoration sites should be prioritized according to their regenerative potential. This includes not only sites with adequate acorn production and dispersal capabilities, but also with adequate biophysical (conditions e.g., soil, water table, etc.) to support seedling growth and cultivated transplants. A GIS-based system for evaluating site suitability for valley oak restoration is being developed for Santa Barbara County by Frank Davis and associates at the University of California, Santa Barbara (Davis and Kuhn, in press, http://www.biogeog.ucsb.edu/projects/sboak/sboak.html).

OBJECTIVE 4

Restore protected oak woodland systems to benefit healthy bird populations.

Recommendations

4.1. Restore oak woodlands to promote oak regeneration.

Regeneration is a problem in oak woodlands with a large amount of oak mortality and not enough growth of seedlings and saplings to replace dying trees. In these areas, land managers may want to promote regeneration by protecting young trees from grazing and browsing animals or by planting acorns or seedlings. Because planting oaks requires intensive effort, it may be more efficient in some sites to protect seedlings and saplings where they are already present. Small oak trees may need protection from grazing animals until they have grown taller than the browse line. Active restoration of oak trees may be needed most on drier south-facing slopes (Brooks and Merenlender 2001). A variety of devices, such as screens and plastic tubing, as well as brush piles, can discourage browsing of small trees. A recent University of California manual on "Regenerating Rangeland Oaks in California" (McCreary 2001) is available through the UC Integrated Hardwood Range Management Program (IHRMP). Contact information for IHRMP and sources of other information on how to implement oak woodland restoration are available in Chapter 9.

4.2. Restore understory components of oak woodland systems.

Many oak woodland birds are associated with grassland and shrub components of oak woodlands (Tables 3-1 and 3-2). Oak woodlands with a shrubby understory and downed woody material support greater numbers of small vertebrates (Tietje and Vreeland 1997, Teitje et al. 1997). The presence of shrubs and brush piles in the understory of oak woodlands may also help promote the survival of oak seedlings (Callaway 1992b, Callaway and Davis 1998, Weitkamp et al. 2001).

4.3. Replace non-native annual grasses with native perennial grasses in oak woodland systems.

Re-establishing or conserving native perennial grasses in oak woodlands may benefit oak regeneration, because non-native annual grasses tend to outcompete young oak seedlings for soil moisture (Gordon and Rice 1993). Also, some birds, such as the Lark Sparrow, may benefit from the presence of native grasses (Martin and Parrish 2000).

4.4. Restore upland oak woodland habitats in conjunction with adjacent riparian restoration.

Many bird species use both riparian and upland oak habitats for different parts of their life cycle. For example, birds that breed in oak woodland habitat may use riparian habitat as corridors for the dispersal of juveniles and non-breeding adults. Riparian habitat may also be used for foraging and as migratory stopover grounds. In addition, birds nesting in riparian habitat adjacent to native upland habitat may experience lower rates of nest predation or cowbird parasitism (RHJV 2000).

4.5. Restore natural fire regimes in oak woodlands whenever possible.

Higher fire frequencies in the era before widespread fire suppression (before the 1950's) may have created conditions that favored oak regeneration (Chapter 10 in Standiford and Tinnin 1996). Thus, restoring natural fire frequencies may contribute to improved oak recruitment. Also, low-intensity prescribed burns may help reduce fuel levels and prevent large, higher intensity fires that destroy oak stands. However, oak woodlands may also be damaged when fire frequency is too high, and the idea that changes in fire frequency have influenced oak regeneration is not entirely supported by recent studies (McCreary 2001, Swiecki and Bernhardt in press). More study is needed to identify the optimal fire frequency in oak woodlands. Therefore, this is a good area for adaptive management, which requires monitoring of the effects of different prescribed burning regimes on oak woodland plants, birds, and other wildlife.

4.6. Restore a mosaic configuration of a diversity of oak woodland types.

See Recommendation 1.4.

4.7. Restore oak woodlands to meet the requirements of cavity-nesting birds.

Cavity-nesting birds make up a large proportion of the bird species and a majority of the individual birds breeding in oak woodlands (Wilson et al. 1991). Therefore restoration programs should give special consideration to meeting the habitat requirements of this guild, including both primary and secondary cavity nesters. See Recommendations 6.3, 6.4, and 6.7.

Oak Titmouse *photo by Ian Tait*

4.8. Plant multiple species of oak tree when restoring oak woodlands

Sites with more than one species of oak present are more likely to support stable populations of Acorn Woodpeckers (Koenig and Haydock 1999). Other acorn-consuming species will benefit from this as well, because high oak species diversity helps to ensure that acorns will be available from at least one type of oak in a given year.

Management Recommendations

OBJECTIVE 5

Implement and time land management activities in oak woodlands to increase avian reproductive success and enhance populations.

Recommendations

5.1. Avoid the construction or use of facilities and pastures that attract and provide foraging habitat for European Starlings and Brown-headed Cowbirds.

European Starlings and Brown-headed Cowbirds are insectivorous ground feeders, and therefore are attracted to pastures, other open, short-grass areas and feedlots (Morris and Thompson 1998, Purcell et al. in press). Brown-headed Cowbirds parasitize songbird nests and European Starlings compete with native species for nesting cavities (Troetschler 1976). Recent studies suggest that European Starling populations may be increasing in oak woodlands and may be more likely to nest and forage in or near grazed oak woodlands or pastures than in the center of ungrazed areas (Verner et al. 1997, Purcell et al. in press). The degree to which Starlings and Cowbirds impact native oak woodland bird populations is still

uncertain, but their presence is likely to be detrimental for some native species. Further research is also needed to investigate whether pastures and rangelands can be managed so as to reduce their attractiveness to Starlings and Cowbirds.

5.2. Brown-headed Cowbird trapping should only be used as an interim/ emergency measure.

Cowbird control has been effective in stabilizing declines of endangered species in limited populations breeding in riparian habitats. For example, cowbird trapping lowered parasitism rates in a Willow Flycatcher population on the South Fork Kern River (RHJV 2000), and populations of Least Bell's Vireos at Camp Pendleton appear to be increasing as a result of cowbird trapping (USFWS 1998). However, endangered species can never fully recover as long as they rely upon human intervention for their survival (Kus 1999). A National Cowbird Advisory Council was formed to address trapping issues, review trapping programs on a case by case basis, and advise land managers and regulatory agencies. Expert opinion suggests that cowbird trapping is at best a temporary stopgap solution, and it is preferable to manage habitat and human use in ways that lessen the negative impacts of cowbirds (Morrison et al. 1999, and the National Cowbird Advisory Council).

5.3. Limit restoration activities and disturbance events such as grazing, prescribed fire, firewood harvesting, disking, and herbicide to the non-breeding season (which varies by region, but is typically August through February in California).

Such disturbances during the breeding may have direct impacts on the nesting success of oak woodland species, especially ground or shrub nesters. These activities may be much less detrimental to birds if conducted during the non-breeding season. Although few studies have directly tested this hypothesis, a recent study found no effect of an October prescribed burn on bird abundance in coastal-central California oak woodland (Tietje and Vreeland, in press).

The effects of grazing in particular need further study. While grazing did not appear to have a large effect on oak woodland bird densities at the San Joaquin Experimental Range (Verner et al. 1997), further study is needed into possible effects on primary population parameters such as reproductive success. Grazing probably contributes to the long-term lack of oak recruitment in many areas, which will in time have serious consequences for bird populations. Thus, grazing should be managed so as to promote oak recruitment. There is some evidence suggesting that winter grazing is less damaging to blue oak seedlings than spring or summer grazing (Hall et al. 1992).

Grazing, prescribed fire, and mechanical treatments such as disking can be useful tools in habitat restoration, for example to promote the growth of native perennial grasses (Tu et al. 2001). In some cases, these treatments may be most effective during the breeding season. If so, land managers should carefully weigh the long-term benefits of the management action against the short-term costs to avian productivity. Long-term use of such treatments in the breeding season should be avoided.

5.4. Manage for a grass and shrub understory where bioregionally appropriate.

See Recommendations 4.2 and 4.3.

5.5. Manage or influence management at the landscape level.

Managing at the landscape level means taking into account interactions among the different habitat patches and ecosystems that make up a region. The presence and abundance of birds in a patch of oak woodland can be influenced by characteristics of the habitat mosaic surrounding the patch, as well as by characteristics of the individual patch (Sisk et al. 1997, Stralberg and Williams, 2002). Linking and buffering large sections of oak woodland and associated habitats may restore top predators, such as coyotes or bobcats, to the oak woodland system. These predators may, in turn, reduce populations of avian nest predators such as skunks, raccoons, and snakes (Soulé et al. 1988). Landscape-scale land-use patterns may affect the population levels of Brown-headed Cowbirds and avian predators in an area, and thus reduce avian productivity. However, research on the demographic effects of habitat fragmentation is lacking for California oak woodlands, and one study in a western landscape suggests that fragmentation may not always cause increased nest predation (Tewksbury et al. 1998). More generally, the theory of island biogeography predicts the gradual extirpation of small populations from isolated habitat fragments (MacArthur and Wilson 1967). Landscape-scale management is also needed to prevent the invasion of protected habitat patches by exotic plants and animals (e.g., Suarez et al. 1998). Implementing landscape level management often will require cooperation with regional organizations such as regional fire councils, weed abatement districts, watershed conservancies, and Resource Conservation Districts.

OBJECTIVE 6

Protect, enhance or recreate natural oak woodland processes and characteristics.

Recommendations

6.1. Maintain diverse age structure of oak trees.

See Recommendation 1.3.

6.2. Protect seedling and sapling trees to enhance oak recruitment.

Oak seedlings and saplings remain vulnerable to damage by herbivorous animals, including grazers, browsers, and small mammals, until they have grown taller than the grazing line (usually about 5 feet). Mangers may want to consider placing protective structures around these young trees.

6.3. Retain decaying or dead oak trees, limbs, snags and mistletoe.

Some cavity-nesting birds, such as the Plain Titmouse and White-breasted Nuthatch, nest primarily in natural cavities (Wilson et al. 1991). Therefore, the injured and decaying trees in which these cavities often form are an important habitat element for these species. Allowing dead limbs to remain on living trees may provide entry points for decay-enhancing organisms, which in turn allow birds to excavate cavities in the rotting wood. An analysis using the California Wildlife Habitat relationships System (CWHR) estimated that over 50 species of birds use snags for breeding, feeding and/or cover (Guisti et al. 1996). Mistletoe is known to be an important winter food for Western Bluebirds (see Species Account for details).

6.4. Retain large oak trees whenever possible.

Acorn Woodpeckers will benefit from the presence of large diameter trees (> 50 cm DBH), which they prefer to use for nesting and as granary trees (Gutierrez and Koenig 1978, Wilson et al. 1991). One study in the Bay/Delta bioregion found that granaries were almost exclusively found in deciduous oaks greater than 75 cm in diameter (Wilson et al. 1991), while softwoods such as pines are preferred in other areas (see species account for more details). Sustaining Acorn Woodpecker populations is likely to be beneficial to secondary cavity nesting species, such as Western Bluebirds, which often use old excavated nests. Large trees often contain many natural cavities for nesting birds, and are disproportionately chosen for site sites by Red-tailed Hawks (Tietje et al. 1997a) . See recommendation 1.3.

Large oak trees also produce more acorns than smaller trees, providing both a source of oak recruitment and food for wildlife. Therefore, in the absence of any data on actual acorn production, the largest trees should be retained. Also, certain individual trees may produce more acorns, have more large branches and produce larger snags and logs for wildlife use than other trees. Therefore, these especially valuable individual trees can be identified and retained to benefit birds and other wildlife. The acorn production of individual trees can be visually estimated in early fall (for instructions, see McKibben and Graves 1987 or Guisti et al. 1996). Acorn crops vary from year to year, so Guisti et al. (1996) recommend observing individual trees over 2-3 years and McKibben and Graves (1987) recommend observing trees in at least one high acorn production year. If data from multiple years are not available, it would still be beneficial to retain those trees that produce the most acorns in any given year, because the same individual trees tend to be good producer from year to year (Chapter 9 in Standiford and Tinnin 1996).

6.5. Control and eradicate non-native animal species.

The presence of non-native animals, such as European Starlings, feral cats, and pigs, may be harmful to native birds. Non-natives may compete with or prey on native birds, or may impact the suitability of oak woodlands for birds via their effects on vegetation. A recent study suggests that feral pigs may have significant negative impacts on acorn availability for wildlife and the establishment and growth of oak seedlings (Sweitzer and Van Vuren in press).

6.6. Utilize thinning of oak woodlands as a replacement for complete oak removal in rangelands.

It may be very difficult for oak woodlands to reestablish themselves after being completely removed (Brooks and Merenlender 2001). Much regeneration takes place under the canopy of larger trees where optimal conditions for establishment exist, e.g. moisture, nutrients (Swiecki and Bernhardt 1998). For example, blue oak seedlings do not survive well in areas without some canopy cover. The conversion of oak woodlands to grasslands will obviously cause reductions in the numbers of oak woodland birds present. There is some evidence that thinning of oak woodlands may not have dramatic negative effects on common oak woodland birds, especially if small patches are thinned (3 ha or less), if thinning reduces the basal area of trees by < 25%, and if large trees, trees with nest cavities, and Acorn Woodpecker granary trees are preserved (Aigner et al 1998). Leaving brush piles after thinning may cause increases in population density of some bird species, such as California Quail and Bewick's Wren. However the effects of thinning on uncommon species is uncertain. If oak woodlands are thinned, the most valuable trees for wildlife should be preserved (Garrison and Standiford 1997), as outlined above in Recommendations 6.3 and 6.4.

6.7. Manage for a diversity of oak species within the appropriate bioregion.

Research has shown that cavity-nesting birds use a variety of trees for nest sites, suggesting that these birds will benefit from having many alternative nesting substrates available (Wilson et al. 1991). Because different oak species do not mast synchronously, high oak species diversity will also help ensure that acorns will be available from at least one type of oak in a given year, thus benefiting acorn-consuming birds (Koenig and Haydock 1999).

6.8. Design and implement cultivated restoration projects that mimic the diversity and structure of a natural oak woodland plant community.

The response of birds to riparian habitat restoration suggests that cultivated restoration sites are more beneficial to birds if they mimic the diversity and structure of naturally occurring habitats (RHJV 2000). If this is also true in upland habitats, then some of the cultivated restoration recommendations in the Riparian Bird Conservation Plan may be applicable to oak woodlands. For example, this would suggest that restoration projects should include the planting of multiple species of trees as well as native understory plants such as shrubs, herbs, and grasses. Also, planting oak trees in a clustered pattern or planting young trees under the canopy of existing trees may promote the recruitment of additional oaks and benefit birds.

6.9. Maintain corridors between oak woodlands and other habitats.

Many of the birds found in oak woodlands use other habitat types during parts of their life cycles. Therefore, the diversity of birds and the health of their populations will likely be greater when oak woodlands are connected to other habitats by corridors of native vegetation.

6.10. When harvesting firewood in oak woodlands, identify and retain important resources for wildlife.

The results of one study on light firewood harvesting (basal area of trees reduced by less than 25%) in a California oak woodland suggest that protecting granary trees, nest cavities and some dead limbs, creating brush piles, and harvesting in small patches may help maintain bird populations in harvested oak woodlands (Aigner et al. 1998). In addition, Standiford (1996) recommended that following guidelines be followed: preserve individual trees which produce the most acorns, preserve at least one snag (i.e., dead tree) per acre, allow buffer zones with no harvesting adjacent to riparian areas, and protect sprouting stumps and existing small seedlings and saplings. Guidelines for how to identify which blue oaks produce the most acorns can be found in McKibben and Graves (1987). More research is needed to understand the long-term, large-scale effects of firewood harvesting in oak woodlands.

OBJECTIVE 7

In private commercially managed oak woodland habitats (i.e. vineyards, agricultural fields, and housing developments), maintain habitat characteristics sufficient to support native bird populations. Work cooperatively with agricultural researchers to encourage vineyards and orchards adjacent to existing oak woodlands to be more "bird friendly."

Recommendations

7.1. Retain connected oak patches within managed landscapes.

Developed or agricultural areas may still provide habitat for some oak woodland birds if oak patches are retained (Scott 1993, Stralberg and Williams, 2002). The long-term health of these bird populations is not known, but is likely to be improved by connectivity among retained oak patches. See recommendation 10.1.

7.2. Retain oak trees in addition to herbaceous, grass or scrub understory.

Oak removal has historically been recommended to increase forage production for livestock. However, research suggests that removing blue oaks results in little or no improvement in forage production in areas receiving less than 20 inches of rain per year (see review of research in Chapter 5 of Standiford and Tinnin 1996). Indeed, in drier parts of the state, deciduous oak canopy cover can enhance forage production. Rangeland experts also recommend that areas where oaks are thinned should retain oak canopies of at least 25-35% to help maintain soil fertility, minimize soil erosion, and provide wildlife habitat (ibid.).

7.3. Maintain oaks around residences and other landscaped areas by avoiding soil compaction and over-watering.

Native oaks are valued parts of many yards and parks, and may be harmed by soil compaction or inappropriate irrigation. For example, watering near the base of a native oak during the warm season can cause root and crown rot. Detailed instructions for oak care are available from the California Oak Foundation and the UC Integrated Hardwood Range Management Program (see Appendix A for contact information).

7.4. Retain patches of chaparral, riparian or grassland habitats adjacent to patches of retained oaks.

The presence of these habitats adjacent to oak patches may improve conditions for native birds. See also recommendation 1.5, 1.6, and 4.4

7.5. Avoid attracting non-native bird species.

Non-native birds may compete with native birds for resources, including nest cavities. In oak woodlands, European Starlings are of particular concern in this regard. See also recommendations 5.1 and 6.5.

7.6. Avoid attracting or supporting inflated populations of nest predator species.

Homeowners can avoid this by not providing food for avian nest predators such as jays, magpies, crows, and ravens in the breeding season and by not feeding stray or feral cats.

7.7. Refrain from utilizing pesticides or herbicides if possible.

Within developed areas, landowners may benefit bird populations by avoiding landscaping methods that require the use of pesticides. Agricultural landowners adjacent to oak woodland habitat may use integrated pest management or organic productions as an alternative to pesticide use. This prevents damage to nesting birds and increases available foraging habitat.

7.8. Retain natural cavities instead of using nest boxes, whenever possible.

The loss of naturally occurring cavities cannot be completely mitigated by providing nest boxes. Although nest boxes can provide good nesting sites for several species of cavity nesting birds, they also have the potential to alter the composition of the bird community by benefiting some species more than others (Purcell et al. 1997, Mummert et al. in press). Also, if not properly maintained year after year, nest boxes can provide nest sites for non-native species such as European Starlings. Therefore, it is preferable to retain natural cavities whenever possible. In addition, nest cavities may not be a limiting factor in all oak woodlands, and natural nest availability should be assessed before implementing nest-box programs in oak woodlands (Waters et al. 1990).

7.9. Conduct management activities such as mowing herbaceous and grass layers in the non-breeding season.

See recommendation 5.3.

7.10. Seek opportunities to work with landowners and influence the layout of new vineyards to be located in oak woodlands, to ensure that oak harvest or reduction conforms as much as possible to the above recommendations.

OBJECTIVE 8

Inform private landowners of the imminent decline of oak woodlands due to habitat loss and lack of regeneration, and of the subsequent effect on landbird populations.

Recommendations

8.1. Support active outreach to private landowners through established programs such as local Resource Conservation Districts, the Natural Resources Conservation Service, and UC Cooperative Extension.

Many landowners may be interested in managing for oak woodland birds if given the opportunity to do so on a voluntary basis. Resource Conservation Districts can use their established contacts with private landowners as the basis for providing information on how to manage for oak woodland birds. For example, wine-grape growers are often interested in deploying nest boxes on their land to benefit cavity nesting songbirds and owls that may prey on pest insects and rodents. Therefore, the Southern Sonoma Resource Conservation District has recently begun a project to monitor avian reproductive success in nest boxes on Sonoma County vineyards. This project, which is a collaboration between private landowners, the RCD, UC Extension researchers, and PRBO, will provide information to landowners about the use of nest boxes in vineyard-oak woodland habitats. Such programs should be encouraged to help inform and build partnerships with private landowners.

Monitoring/Research Recommendations

OBJECTIVE 9

Provide data on pressing conservation issues affecting birds.

Recommendations

9.1. Consider reproductive success and survival rates when monitoring populations, assessing habitat value, and developing conservation plans.

The value of a habitat for oak woodland birds depends largely on their ability to survive and reproduce there (Block and Morrison 1987). Although many monitoring programs focus on species' abundances, abundance alone is an inadequate, and sometimes misleading, measure of habitat quality (Van Horne 1983). Likewise, long-term trends in bird populations depend

on survival and reproductive success rates. Therefore, monitoring programs should include the estimation of these demographic parameters whenever possible.

9.2. Conduct intensive, long-term monitoring at selected sites. In order to analyze trends, long-term monitoring should continue for more than 10 years.

Intensive long-term monitoring can provide crucial, habitat-specific information on bird population trends. Because oak woodland bird numbers are highly variable from year to year (e.g., Verner and Purcell 1999), most monitoring projects will need to continue for at least 10 years to be able to detect significant trends in abundance or to provide reliable baseline data (Verner et al. 1996). A long-term study of oak woodland birds by Forest Service biologists at the San Joaquin Experimental Range has produced many useful guidelines for designing and implementing a monitoring program (Verner and Ritter 1985, Verner 1987, Verner and Milne 1989, Verner et al. 1996). A project is currently underway, using this long-term dataset, to determine the optimal sample size and number of years required to detect population trends using point counts.

Because apparent trends in oak woodland bird populations can be caused by climatic factors, such as a period of low precipitation, rainfall and temperature should be included as explanatory variables in trend analyses (Purcell et al. in press).

9.3. Conduct selective monitoring at critical sites to determine the factors influencing nest success of representative open cup nesters: Lark Sparrow, Blue-gray Gnatcatcher, Western Scrub-Jay, California Thrasher, California Towhee and Hutton's Vireo.

Low productivity can be an important factor leading to population declines and local extinctions in open-cup nesting birds (Johnson and Geupel 1996, Gardali et al. 2000). By determining the factors associated with low reproductive success, research may identify which management and restoration actions will help prevent or reverse songbird population declines. Land managers, owners and regulatory agencies gain greater freedom in their decision-making if they conserve bird species before special-status listing becomes necessary. Monitoring key species provides gauges that allow management changes before it is too late.

Monitoring sites ideally should be selected in a methodical, randomized fashion so that the effects of various local habitat, landscape, and management conditions on reproductive success can be evaluated through statistical inference. Anthropogenic factors of interest include: grazing, prescribed fire, mowing, development density, landscaping and garden characteristics, and abundance of non-native predators.

9.4. Monitor nests in natural or excavated cavities.

Because cavity nesters make up a significant proportion of oak woodland birds, it is essential to understand the influences on their productivity when nesting in natural cavities (as opposed to artificial nest boxes). The impact of competition for nesting cavities by European Starlings on native birds should also be monitored.

9.5. Monitor effects of Western Scrub-Jay and Yellow-billed Magpie populations on other oak woodland species.

Western Scrub-jays and Yellow-billed Magpies can act as predators on the nests of other native birds (Purcell and Verner 1999). Although jays and magpies are native to oak woodland habitats, they may be a conservation threat in areas where their populations are increased due to human activities. For example, Western Scrub-jays are known to be more abundant near human developments (Merenlender et al. 1998, Stralberg and Williams, 2002).

9.6. Monitor effects of Brown-headed Cowbird and European Starling populations on other oak woodland species and research how habitat management can be used to minimize adverse effects.

See recommendation 5.2.

OBJECTIVE 10

Use information gathered in avian monitoring programs to test specific oak woodland habitat needs for bird species.

Recommendations

10.1. Identify minimum thresholds of connected oak woodlands in urban, agricultural and vineyard fragments.

To assist in conservation planning, we need to know, for example, what is the minimum number of oaks and maximum spacing between oaks that will still provide habitat for oak woodland bird species. Such information will help landowners practice "bird friendly" agriculture and development.

10.2. Study edge effects in oak woodland habitats.

Research into how oak woodland habitat edges relate to bird use, nest predation and cowbird parasitism is needed. There is some evidence suggesting that nest predation rates are lower at "soft" habitat edges than at abrupt, "hard" edges (Suarez et al. 1997, Soderstrom et al. 1998). However, no research on this subject has been conducted in western oak woodlands. Given that many of our protected oak woodlands may border unprotected or developed lands, it is important to know if edges can be managed or restored so as to minimize negative edge effects.

10.3. Compare areas heavily affected by Sudden Oak Death with those that are not, with attention to effects on acorn production, and how that affects the food chain.

Sudden Oak Death might affect bird populations through changes in forest structure and resulting changes in acorn supply and invertebrate numbers, which could potentially spread throughout the food web. Because the effects of SOD on bird populations will probably develop over a long time period, long-term, large-scale monitoring as well as shorter-term, intensive research efforts are needed. Bird monitoring projects in oak woodlands should routinely include the standardized collection of data on stand structure, including numbers of dead or dying trees, along with other habitat data.

10.4. Examine winter use of oak woodlands by bird species.

Relatively little is known about the winter ecology of oak woodland birds. More study is needed to understand which species depend on oak woodlands in winter and what characteristics of oak woodland best promote over-winter survival.

10.5. Study the association between the shrub understory and oak woodland avian diversity and composition.

Continued research on the current and historic occurrence of shrub understory and its value for birds is needed to evaluate the importance of managing for this vegetation layer in oak woodlands (Tietje and Vreeland 1997, Teitje et al. 1997).

OBJECTIVE 11

Study the effects of management practices on oak regeneration and bird populations.

Recommendations

11.1. Monitor the effectiveness of progressive grazing regimes for increasing the rate of successful oak tree regeneration.

It has been suggested that rotational grazing on subdivided pastures can increase the vigor of native grass species, reduce weeds, and promote oak regeneration (George 1991), but little research has yet been done to evaluate this management technique in oak rangelands (but see Jansen et al. 1997). The effects of specific grazing management strategies on oak regeneration and avian productivity should be studied in an adaptive management framework.

11.2. Study the effectiveness of prescribed fire to reduce non-native annual grasses and facilitate germination and growth of oak seedlings.

As outlined in Recommendation 4.5, fire is a natural process that influences oak recruitment and oak woodland structure. While light intensity fires may benefit oak growth by reducing competition with annual grasses, higher intensity fires can also damage young oaks (Teitje et al. 2001). More research on issues such as fire timing and frequency is needed to understand

how prescribed fire can best be used to promote oak regeneration, while also benefiting oak woodland birds.

11.3. Study the effectiveness of "wildlife-friendly" agricultural practices in vineyards and vineyard landscapes.

The winegrape growing industry is increasingly interested in making vineyard development and management less detrimental to birds and other wildlife. The effects of these efforts on birds should be monitored and compared with more traditional management practices in several bioregions.

Vineyards in oak habitat *photo by Geoff Geupel, PRBO*

OBJECTIVE 12

Maximize the effectiveness of ongoing monitoring and management efforts.

Recommendations

12.1. Increase communication and coordination between land managers and specialists hired to implement specific projects or conduct monitoring.

Adaptive management is given much attention and is widely discussed, but land managers rarely have adequate time to evaluate the effects of their projects. When managers work with specialized experts, they have an excellent opportunity to conduct "adaptive management" on an informal basis. Experts, such as those conducting endangered species or biodiversity inventories, should be consulted and included as part of project implementation teams. By doing so, managers can quickly and easily access a wealth of detailed information about local birds, other wildlife, and their responses to management activities.

12.2. Use standardized monitoring protocol.

By standardizing monitoring techniques, researchers ensure that results can be compared across space and time. The USDA Forest Service published guidelines for standardized techniques of monitoring birds (Ralph et al. 1993). Please refer to Appendix B for more information. Standardized methods for measuring habitat variables, such as vegetation structure and composition also should be developed and adopted. Oak woodland databases should also be standardized to facilitate the sharing of Geographic Information System (GIS) datasets.

12.3. Sierra Nevada Framework efforts should seek to incorporate a program of monitoring bird populations to assess avian responses to blue oak woodland and montane hardwoods management alternatives.

12.4. Natural Communities Conservation Planning (NCCP) and development mitigation projects initiated by cities, counties, developers or other land managers should seek to incorporate long-term monitoring and current information on avian populations.

Policy Recommendations

OBJECTIVE 13

Encourage the development of new programs with two complementary goals: (1) make it easier for private landowners to foster oak regeneration on their property, and (2) make it more difficult for large-scale clearing of oak woodland to take place without adequate mitigation.

Recommendations

13.1 Support focused and creative action by the California Wildlife Conservation Board (WCB) in implementing the recently (2001) passed Assembly Bill No. 242, the Oak Woodland Conservation Act (the Act).

This bill authorizes the establishment of the Oak Woodland Conservation Fund for the protection and conservation of oak woodlands throughout the state of California, to be administered by the WCB. The Oak Woodland Conservation Fund may be used to offer financial incentives to private landowners to protect and promote biologically functional oak woodlands over time. Conservation easements, land improvement, and public education and outreach are some of the activities that may be funded as a result of this bill.

The WCB program has exciting potential for working creatively and constructively with landowners to promote good land stewardship. A program to encourage and facilitate efforts to improve oak regeneration on private lands should be emphasized statewide.

Conservation groups, Resource Conservation Districts, city and county planning departments, parks departments and private landowners should focus on the following specific objectives with respect to implementation of the Oak Woodland Conservation Act:

1. Support continued legislative appropriations to the Oak Woodland Conservation Fund on an annual basis.
2. Seek to maximize the benefits of proposed oak woodland conservation programs and projects by coordinating with local land use planning agencies and zoning guidelines.
3. Seek to influence the development of local jurisdiction "oak management plans" (required by the Act) to ensure that the ecological components necessary to support a diverse avian/wildlife oak woodland community are incorporated.
4. As provided for in the Act, seek to participate in developing the guidelines and criteria for awarding grants under this program.
5. Support or promote the use of appropriate sources of federal conservation funding for deposit into the Oak Woodland Conservation Fund. Appropriate federal sources include CARA (the Conservation and Reinvestment Act).

13.2. Promote the passage of legislation that would make large-scale removal of oaks in intact oak woodlands subject to the California Environmental Quality Act (CEQA).

Unless the environmental and cumulative impacts of oak woodland removal are considered prior to approval of land development projects, continued unmitigated habitat loss and fragmentation will occur. CEQA compliance for oaks woodland impacts may help to decelerate the loss and fragmentation of oak woodland habitats, particularly in the wine growing regions of Northern California.

13.3 Promote legislation that provides funding for oak woodland research, monitoring and management.

13.4. Promote the passage of oak preservation ordinances and smart-growth planning initiatives at the local (city and county) level, including:

- County and city general plan updates.
- Collaborative, inter-agency regional planning efforts.

County planning agencies are often interested in incorporating the conservation of oak woodland habitats into their comprehensive plans. Examples include the effort of Santa Barbara county to design an Oak Protection Program for the county's rural areas (Leider, in press, www.sbcountyplanning.org) and Placer County's Legacy Open Space and Agricultural Conservation Program (www.placer.ca.gov/planning/legacy/legacy.htm). Although often controversial, such policies and ordinances should be supported by conservation science and should include measurable performance standards that focus on protecting large patches of oak woodland habitat, not just individual trees (Harris and Kocher, in press).

Chapter 9. Outreach and Education

Scientific efforts for conservation have little impact without the support of affected local communities, including private landowners, government land managers, and the general public. To gain crucial support, research and management programs must share their findings and involve the interested parties at all levels of the conservation enterprise.

For the purposes of this chapter, outreach refers to communication with land managers, agencies, planners, business interests, nonprofit organizations, academia, and volunteers. Outreach activities include conferences and workshops that facilitate communication among experts, participation in land use planning, volunteer restoration and monitoring programs, field trips and classes for school children, and ecotourism.

Education, an important component of outreach, refers to the range of activities that educate and involve students and adults. Education activities include visits for classes and groups to field sites, interpretive displays, specialized curricula, and participation in festivals.

Project-Based Learning

One method of educational outreach, called project-based learning, allows an open-ended approach to solving a conservation problem. Students identify a conservation issue in their community and plan and implement conservation projects from beginning to end. Teachers and students make the important decisions, while working with biologists, business people, private landowners and others in the community. Because of this investment, students take ownership of their work, and the lessons learned are profound and long-lasting (Rogers, pers. comm.).

Conservation education sensitizes people to environmental problems and encourages them to seek solutions. As they become involved, people develop a greater connection to issues such as habitat degradation and loss, songbird declines, and species extinction. Conservationists have little hope of achieving their goals without cultivating this interest in the public.

Education programs engage participants most effectively when they involve hands-on activities. Conservation education has the whole of the outdoors as a classroom–what better way to elicit the interest and enthusiasm of students and the public?

Education Opportunities

Since oak habitats are such noticeable and accessible habitats, they provide excellent opportunities for hands-on experience for school groups. In fact, many schools and homes are surrounded by areas of open space containing oak woodland habitat. This close

proximity creates easy access for field visits to observe birds and other wildlife in this habitat. In addition, many oak woodland areas contain a bluebird nest box program. If you are involved in a bluebird nest box program make sure you are not doing more harm then help by following the guidelines of the North American Bluebird Society (http://www.nabluebirdsociety.org/) for proper installment, monitoring, and maintenance of nest boxes. If you would like to start a nest box program or install a nest box at your school, nature center or even home follow all the guidelines of the North American Bluebird Society.

The following is a list of key topics to emphasize in Oak Woodland educational projects:

- The different types of oaks
- The oak lifecycle and its dependency on birds for propagation
- Cavity abundance in oak woodlands supports a high diversity of cavity nesting birds
- The influence of acorns on native peoples culture and their use of fire to stimulate acorn production

The concepts and guidelines outlined above and in the Conservation Education section can be presented to the public and to students through a variety of media. Following is a list of common education opportunities and some suggestions for content:

Classroom Education

Programs in the classroom should focus on communicating key concepts to students through hands-on activities. Lessons should stress studying birds in the field - whether in the backyard, on school grounds, or in a nearby natural area - and include keeping field notes and observing natural behaviors of birds. Field trips to sites with bird conservation and monitoring projects, fosters interest and enthusiasm for wildlife and teaches students the importance of conserving birds.

photo by PRBO staff

A great way to get students interested in birds is to get them out looking at them. While access to binoculars is sometimes limiting, you can contact your local Audubon Society, Nature Center or other local wildlife education group to see if sets are available for check out. If you feel uncertain of your birding skills, contact your local Audubon Society or Nature Center to arrange for docents or naturalists who will be able to join your class for a

day of birding in the field. An invaluable experience that catches students' interest immediately is to visit a mist-netting site where students will have the opportunity to examine birds up close and interact with biologists.

There are many excellent sources for curriculum and hands-on bird activities to be done in the classroom. Through the Point Reyes Bird Observatory, Teacher Resource Packets are available containing lesson plans and activities for students of all ages, geared towards teaching students how to observe and study birds. To acquire the PRBO Teacher Resource packets contact Melissa Pitkin, 4990 Shoreline Hwy, Stinson Beach, CA 94970 (415) 868-1221 ext. 307, or email at **mpitkin@prbo.org**.

Each year PIF produces a resource directory containing bird related resources on education programs and materials, education web sites, activities for kids, workshops, and more. To acquire this guide contact Susan Bonfield, PO Box 23398, Silverthorne, CO 80498 or email Sbonfield@aol.com. Another useful source is *A Guide to Bird Education Resources* produced by Partners In Flight and National Fish and Wildlife Foundation. Copies of this book are available from American Birding Association Sales, PO Box 6599, Colorado Springs, CO 80934, phone 1-800-850-2473, member@aba.org.

Other Oak Woodland Educational Resources

- **North American Bluebird Society:** Bluebird Poster and Pocket Field Guide Student Packet, Bluebird Nestbox Plans, and Bluebird Newsletter P.O. Box 74 Darlington, WI 53530 608/329-6403, email: nabluebird@aol.com; Online at: http://www.nabluebirdsociety.org/.

- **Acorn Naturalists Materials:**
  Available at: http://www.acornnaturalists.com/p905.htm or at 155 El Camino Real P.O Box 2423 Tustin, CA 92781-2423 Phone 1-800 422-8886

- **Investigating the Oak Community**: a curriculum designed to involve 4th through 8th grade students in activities that will develop their awareness, understanding, and knowledge of the important role of oaks in the California landscape. Available at http://www.californiaoaks.org/html/merch2.html.

- **Books on Oaks and Oak Woodland Habitat:**

  Grandmother Oak, Rosi Dagit, Gretta Allison (Illustrator); Roberts Rinehart Pub., Jan. 1997.

  In a Nutshell, (Sharing Nature with Children Book), Joseph Anthony, Cris Arbo (Illustrator); Dawn Publications, Sept. 1999.

  Oaks of California, Bruce Pavlik, Pamela Muick, Sharon Johnson; Cachuma Press, 2000 (revised).

Webs of Life (Oak Tree), Paul Fleisher, Jean Cassels; Library Bindings, January 1998.

The Life of an Oak Tree: An Intimate Portrait, Glen Keator, Susan Bazell (Illustrator); Heydon Books, April 1998.

- **The California Environmental Resources Evaluation System** (http://www.ceres.ca.gov/) has a great list of resources for Natural Sciences Educators at: http://www.ceres.ca.gov/education/educators/nat_sci.html

- **Cal Alive!** An interactive CD-Rom for 4th-8th graders focusing on CA biological diversity. Software is available at the following website: http://www.calalive.org/index-big.html.

Volunteer Involvement

Enlisting volunteers to aid in data collection and restoration is an excellent way to gain additional help. It is one of the best ways to teach people about conservation. Increasingly, families and school groups have opportunities to participate in cultivated habitat restoration projects at local parks or nature preserves. Volunteers that participate in counting and studying birds quickly develop a connection to them, which intimately involves the volunteer in the conservation effort. Furthermore, volunteers provide additional support and resources that make long-term monitoring of songbirds viable. To ensure reliable data collection, supervisors must match monitoring techniques with the skill level of the volunteer.

Volunteer projects monitoring bluebird nest boxes are an excellent way to ensure that bluebird boxes are monitored as well as providing a wonderful opportunity for volunteer involvement. If you are coordinating a volunteer bluebird nest box project please follow the guidelines of the **North American Bluebird Society**. You can find these guidelines on-line at http://www.nabluebirdsociety.org/.

Interpretation at Natural Areas

Interpretation is an excellent way to disseminate key concepts about bird conservation to the public. Displays at preserves, nature trails, picnic areas, and other natural areas should highlight the birds using the habitats and show the specific features of the habitat that are critical to bird reproduction and survival, including native plants. Some effective displays illustrate how individuals can make a difference at home, by planting native plants in their yards or restraining cats from killing birds. These displays should be aimed at the general public, emphasizing the causes of the decline of songbirds. Again, integrating people as part of the solution encourages their support for conservation issues.

Participation in Birding Festivals and Environmental Fairs

Birding festivals are becoming a popular means of increasing ecotourism, which can help to promote local support for conservation of natural areas–a requirement for long-term sustainability of conservation actions. Festivals also present an excellent opportunity to further educate people already familiar with birds about the scientific reasons behind bird conservation. Birders already recognize and love birds and can easily be taught the reasons for bird conservation and what a healthy population of birds needs to survive. They also constitute a pool of experienced observers who may volunteer for monitoring programs. The second Saturday in May is International Migratory Bird Day and National Keep Your Cat Indoors Day. Creating a display or festival in honor of these days is a great way to spread the word about bird conservation to your community.

Representation of bird conservation at environmental fairs is another way to reach large numbers of people and convey the key concepts behind bird conservation. Booths displaying information on how individuals can help birds along with interactive games or activities for children engage families and visitors in bird conservation topics.
The National Fish and Wildlife Foundation has published Bridges to Birding, an interactive program for introducing birds, bird watching and bird conservation to your community. It contains step by step instructions on how to put on a festival or fair focusing on birds. To obtain a copy contact IMBD Information Center at (703) 358-2318 or **IMBD@fws.gov**. For more information on National Keep Your Cat Indoors Day, contact the American Bird Conservancy or visit **http://www.abcbirds.org/cats/catsindoors.htm.**

Oak Woodland Outreach

Many groups are already working together on projects to preserve and educate people about Oak Woodland habitats. Activities ranging from workshops, management guidelines, new partnerships, and educational curriculum are being conducted by these groups. The groups and their activities are summarized below:

The California Oak Foundation (COF) was founded in 1988, and provides technical assistance and educational materials to those engaged in protecting oak woodlands and planting oak trees.

The California Oak Foundation works to:

- Encourage adoption of state laws protecting oaks, general plan amendments, ordinances by local, regional, and state agencies to conserve oaks;

- Co-publish oak books and educational materials, including "Oaks of California," "The Life of an Oak," and "Compatible Plants Under and Around Oaks;"

- Develop educational curriculum and provide information to schools and other community groups for acorn planting and tree maintenance projects;

- Educate decision makers, individuals and communities about threats to our endangered oak heritage;

- Sponsor technical conferences on oak preservation and workshops on estate tax planning and conservation easements in urban and rural environments for planners, developers and landowners.

For more information see Appendix A: Resources.

University of California Integrated Hardwood Range Management Program
http://128.48.5.253/ihrmp/

The Program's purpose is developing alternative land use planning and range management strategies to ensure multiple use of hardwood rangelands while improving oak regeneration and maintaining diverse wildlife habitat.

Objectives:

- Develop methods to sustain hardwood rangeland ecosystems and landscapes;
- Maintain wildlife habitat on hardwood rangelands;
- Restore degraded hardwood rangelands;
- Ensure land use planning utilizing available information to conserve hardwood rangeland ecosystems;
- Maintain economically viable private hardwood rangeland enterprises;

Regional cooperative extension specialists are located throughout the State to develop applied research and outreach programs addressing conservation of hardwood rangelands with local Cooperative Extension offices and various agencies and interest groups. The Extension program also develops newsletters and educational materials. http://128.48.5.253/ihrmp/person.html

Projects of the Program include:

- **Workshops on Guidelines for Managing Hardwood Rangelands** -- 10 workshops were presented in FY 97-98 to extend the concepts in the recently revised handbook, "Guidelines for Managing California's Hardwood Rangelands." Presented in collaboration with local county Cooperative Extension offices. Over 450 ranchers, homeowners, local conservation groups, and resource management professionals participated.

- **Development of Local-Based Oak Woodland Conservation Policies** -- The State Board of Forestry has adopted a hardwood rangeland policy to encourage local or regionally-based conservation strategies, rather than statewide regulations. IHRMP and county CE staff have helped facilitate development of these local policies. During FY 97-98, Sonoma, Fresno, and El Dorado counties implemented new hardwood rangeland

policies. These add to the other 27 counties that have already adopted local hardwood rangeland conservation policies.

- **Monitoring of Hardwood Rangeland Resources** -- Provide local feedback into state-level monitoring carried out by USDA Forest Service (USFS) and the California Department of Forestry and Fire Protection (CDF). Change detection evaluation of seven counties in the southern Sierra Nevada was completed in cooperation with local CE advisors. Work on monitoring sources of hardwood rangeland change started in the central and northern Sierra Nevada regions.

- **Develop and Extend Restoration Efforts** -- Educational programs were held with restoration professionals, native plant nurseries, and landowners on IHRMP-developed hardwood rangeland restoration technologies. Over 150 professionals were reached directly with educational workshops dealing with this topic.

- **Vineyards in an Oak Landscape** --Conversion of hardwood rangelands to vineyards identified as key area for new program thrust. Leaflet developed to describe hardwood rangeland conservation strategies in areas being developed for new vineyards. Local regulatory restrictions proposed in Sonoma, Napa, and Santa Barbara counties, and IHRMP and county CE advisors worked closely in developing educational opportunities to present research-based information in this policy debate. Five educational workshops were held this fiscal year on this topic. A pilot GIS mapping project started in Sonoma County.

- **Economic Value of Hardwood Rangelands** --Concerns about validity of Williamson Act appraisal processes used in the Southern Sierra Counties led to contract with Tulare County Assessor's Office to determine a scientifically defensible appraisal process. This work completed, and extended to southern Sierra Nevada county assessors in a workshop and through printed case studies. Work has helped quantify amenity and conservation value of hardwood rangelands to support developing interest in conservation easements and land trusts to conserve habitat values of hardwood rangelands.

- **California Oak Symposia** –Together with a number of other organizations and agencies, IHRMP recently convened the fifth in a series of symposia on oaks in California. These conferences and their proceedings are rich sources of information on a wide variety of subjects related to oak ecology, management, and conservation (Standiford 1991, Pillsbury et al. 1997).

California Association of Winegrape Growers

CAWG was founded in 1974 to represent the interests and concerns of wine and concentrate grape growers. CAWG has begun to work with the scientific and environmental community to develop and promote awareness of wildlife-friendly vineyard practices. In 2002, CAWG organized a workshop on Vineyards and Wildlife Habitat, and plans to follow up with a publication on the subject. www.cawg.org

Eastern Madera County Coarsegold Resource Conservation District Voluntary Oak Woodland Management Guidelines http://www.crcd.org/
The Coarsegold Resource Conservation District has provided this forum to furnish landowners with the latest information and provide educational material for their use in the management of their property. The data included on this site was developed to assist landowners in becoming better land stewards and direct them to publications and agencies for help in the management of their property.

Phytosphere Research -- (http://phytosphere.com) provides information needed to effectively manage plant resources in urban and rural environments, natural ecosystems, and agricultural systems. They focus especially on ecology, restoration, and management of native California oaks and oak woodlands. Their site *Understanding blue oak regeneration*: (http://phytosphere.com/BLUEOAKF.HTM)
provides and indepth overview of blue oak regeneration, including details on the effects of canopy and site conditions, accounting for historical regeneration patterns, sustainable management, and effects of fire and grazing. They also offer a guide to growing California oak species (http://phytosphere.com/oakplanting/oakplanting.htm)

Future Outreach Priorities

Outreach activities must maintain and build interest in conservation and restoration efforts in the state. To this purpose, outreach efforts should develop:

- **Greater collaboration** between woodland managers (include public and private agencies) and biologists to examine wildlife response to management practices throughout California's varied oak woodland habitats.

- **More contact with resource-based constituencies**, such as the wine-making industry, to foster collaboration in land management, in order to improve habitat for birds while ensuring that landowners can make a sustainable living.

- **Partnership with the National Association of Service and Conservation Corps** (NASCC), of which the California Conservation Corps is a part. The California Association of Local Conservation Corps also has 11 members throughout the state with a trained labor force capable of restoring habitat. These programs improve environmental quality while providing opportunities for young people to learn and develop new skills.

- **Further educational outreach**, particularly the promotion and support of volunteer monitoring programs. Volunteer monitoring programs are most needed at reference sites and others that will require long-term monitoring.

- **Oak Woodland conferences and symposia**. These will highlight recent developments in restoration biology, innovative government programs and public and private

partnerships. They will also facilitate communication among restoration biologists, regulatory agencies, land managers, and landowners throughout the state.

Opportunities for Involvement: What Can One Person Do?

An individual can have a profound impact on the life of a bird and the livelihood of a species. Human activities can encourage predation of adult birds and their nests by animals such as domestic cats, raccoons, and jays. They can alter available food resources by depleting local insects with pesticides. Finally, they can destroy or disrupt much-needed habitat for nesting and feeding young. But thoughtful activity by humans can limit these impacts and even encourage successful nesting by songbirds, contributing to the health of their population.

The guidelines below can make a critical difference in enhancing the health of a songbird population. These recommendations apply to most bird species, including oak woodland birds.

If you are a bird watcher, volunteer for a monitoring program.

There are increasing opportunities for bird watchers of all skill levels to gain training and experience in various bird monitoring techniques. Participants gain knowledge in a subject area of interest, learn new skills, and can directly contribute to the science of conservation while enjoying birds in the outdoors. There are increasing opportunities to contribute to bird monitoring projects in riparian habitats throughout the state. (See the PRBO web site http://www.prbo.org for ways to get involved and Appendices A and B for more information on bird monitoring techniques and the information they provide.)

If you own a cat, help reduce the impact of cats on bird populations.

Domestic cats kill hundreds of millions of native birds, reptiles and small mammals every year. This unnecessary impact can easily be reduced if cat owners would keep their cats indoors. The American Bird Conservancy's Cats Indoors! campaign seeks to educate the public on the facts of cat predation on birds and other wildlife, and the hazards to free roaming cats. This information is available at the American Bird Conservancy's web site at **http://www.abcbirds.org**.

Other actions that cat owners can take to help birds:

- **Keep cats as indoor pets.**
- **Spay and neuter your cats**.
- **Cats on ranches or farms, kept to control rodent populations, should be kept to a minimum.** Spayed females tend not to stray or wander from the barn area. Keeping feed in closed containers also helps reduce rodent populations (Coleman et al. 1997). Trapping rodents can also be more effective than relying on cats to do the job.

- **Don't feed stray or feral cat populations**. A more humane alternative for cats and wildlife is to reduce the unwanted cat population by limiting reproduction and facilitating adoption by responsible pet owners.
- **Remove food dishes or garbage that may attract stray cats.**
- **Support local efforts to remove feral cats.**

If you camp, hike, or picnic in the outdoors help maintain the natural balance between predator and prey.

Do not feed wildlife or allow wildlife access to your trash. This may lead to an increase in natural predators such as raccoons, fox, ravens, crows, jays, and opossum. Increased numbers of these predators can depress bird populations.

If you feed birds, avoid doing more harm than good.

Feeding wildlife can be beneficial if properly done, but it always carries the potential for upsetting the natural balance between native predators and prey species. Improper feeding can help to spread disease, support predator populations that prey on birds and other organisms, or increase non-native populations that displace the natives.

•Feeder placement should be away from shrubs or bushes that provide places for cats to ambush birds (Coleman et al. 1997).

•Avoid feeding birds in the spring and summer. Feeding birds supplements their natural diet, but springtime feeding may encourage a lower quality diet for nestlings who need high-protein insects, which are naturally abundant throughout the breeding season.

•Do not supplement the diet of avian nest predators such as jays, magpies, crows and ravens by feeding them during the breeding season. These predators tend to benefit disproportionately from human habitation, and as their populations expand they are negatively affecting the health of other bird populations. The National Audubon Society produces bird feeders that discourage use by avian predators.

•Avoid supplementing the diet of Brown-headed Cowbirds, which parasitize songbird nests. If cowbirds come to your feeder, try eliminating millet from the birdseed you provide. Evidence indicates that Brown-headed Cowbirds are attracted to bird feeders primarily for millet. Sunflower seeds and other types of birdseed attract many songbird species, but may not attract cowbirds.

•When feeding birds in winter, feed them consistently. Some wintering birds may become dependent upon winter bird feeders, thus a consistent supply of food is important. Change birdseed if it gets wet from rain as the moisture may promote mildew or sprouting, which can cause birds to become ill.

•In feeding hummingbirds, use a solution of four parts water to one part sugar. Do not use brown sugar, artificial sweeteners or red dye. Place the feeders in the shade and change the feeder solution every three to four days to avoid cultivating pathogens that can cause hummingbirds to become ill. In freezing weather, bring feeders indoors at dusk and return them with lukewarm fluid at dawn. Clean feeders every 10 days using a few drops of bleach in the wash water, and let stand before rinsing. Rinse thoroughly many times.

If you find an injured bird or a baby bird:

•Baby birds will often leave the nest before they look fully-grown. Such birds are often mistaken for "abandoned." Their parents, however, can find them on the ground and will feed them. Most fledglings will continue to be fed by their parents even after leaving the nest. It is therefore best to leave young uninjured birds alone, as it is likely their parents are nearby. It is not true that parents will avoid young after humans have handled them. Fledglings should not generally be returned to their nest, as this may disturb the nest site. Trampled vegetation and human activity can alert predators to the presence of the nest. Allowing baby birds to remain in the care of their parents provides them their best opportunity for survival.

•Injured birds can be taken to wildlife rehabilitation clinics and programs. It is best to keep injured birds in a warm, dry, quiet place free from disturbance (such as a shoebox with the lid on and a few holes for air) until they can be transferred to a licensed wildlife rehabilitation facility. Call the facility before you visit.

•Be aware that it is against federal law to collect birds or their nests without a permit.

KEY CONCEPTS ABOUT BIRD CONSERVATION

The following list of key concepts for bird conservation should be communicated through education and outreach programs. These concepts are important to include in any program concerning conservation, and are indispensable in programs focusing on birds and riparian habitats.

- **Reproductive success may be the most important factor influencing population health.** It contributes directly to a population's size and viability in an area. A number of factors influence reproductive success, including predation, parasitism, nest site availability, and food availability.
- **Nesting habitat requirements vary among species.** Different bird species place their nests in different locations, from directly on the ground to the tops of trees. Most birds nest within five meters of the ground. Managers should consider that habitat needs for different species vary. Leave grass and forbs greater than 6 inches in height for ground nesters, shrubs and trees for low to mid-height nesters, dead trees and snags for cavity nesters, and old, tall trees for birds that build their nests in the canopy.
- **The breeding season is a short but vital period in birds' lives.** Birds nest during the spring and early summer of each year and raise their young in a rather short period. Nestlings are particularly sensitive to changes in the environment and are sensitive indicators of ecosystem health. Disturbance, such as vegetation clearing, habitat restoration, and recreation may result in nest abandonment, remove potential nest sites, directly destroy nests, expose nests to predators, and decrease food sources such as insects. Predators, such as domestic cats, skunks and jays, can decimate breeding populations, and managers should avoid subsidizing their populations.
- **Understory (the weedy, shrubby growth underneath trees) is crucial to birds.** A healthy and diverse understory with lots of ground cover offers well-concealed nest and foraging sites. Manicured parks and mowed lawns provide poor nesting conditions for all but a few bird species.
- **Native plants are important to birds.** Native bird populations evolved with the local vegetation, learning to forage upon and nest in certain species. Introduced plant species may not provide the same nutrition or nest site quality. Introduced plants can also quickly dominate an area, reducing the diversity of vegetation. Less diverse vegetation can lower the productivity and viability of a bird population.
- **Natural predator-prey relationships are balance, but human disturbance creates an imbalanced system.** Interactions with predators are a natural and essential part of an ecosystem. However, a preponderance of non-native predators or a sustained surplus of natural predators severely affects the health and persistence of bird populations. Feeding wildlife, especially foxes, raccoons, and skunks, should be discouraged. Feeders that are frequented by jays and crows and cowbirds should not be maintained during the breeding season (most songbirds feed their young insects). Domestic and feral cats are responsible for an estimated 4.4 million birds killed each day by cats (Stallcup 1991). It is not true that a well-fed cat will not hunt! In fact, a healthy cat is a more effective predator.
- **Natural processes, such as flood and fire, are integral to a healthy ecosystem.** They provide the natural disturbance needed in an area to keep the vegetative diversity high, an important factor for birds.

Appendix A. Resources

The Oaks of California by Pavlik et al. (1991)

The California Oak Foundation
http://www.californiaoaks.org/
The California Oak Foundation (COF) is dedicated to protecting and perpetuating California's native oak woodlands and the wildlife habitat and watershed benefits they provide.

Contact information:

California Oak Foundation
1212 Broadway, Suite 810
Oakland, CA 94612
Tel: (510) 763-0282
Fax: (510) 208-4435
E-mail: oakstaff@californiaoaks.org

Also available at this site: *The California Oak Report* Beginning in January 2000, our Current Issues page will feature a monthly report, which will provide information to the general public about the biological role of California's oak woodlands in the landscape and the planning processes applicable to oak woodland habitats. The column also hopes to function as an interactive forum for the discussion of oak issues and as a site for the general public to submit comments, queries, oak news, etc. Automatic monthly electronic mailings of The California Oak Report are available upon request by contacting *oakstaff@californiaoaks.org*.

University of California Integrated Hardwood Range Management Program
http://128.48.5.253/ihrmp/
The Program's purpose is in developing alternative land use planning and range management strategies to ensure multiple use of hardwood rangelands while improving oak regeneration and maintaining diverse wildlife habitat. This site is a tremendous resource for information on anything related to oak woodlands.

OBJECTIVES:

- Develop methods to sustain hardwood rangeland ecosystems and landscapes;
- Maintain wildlife habitat on hardwood rangelands;
- Restore degraded hardwood rangelands;
- Ensure land use planning utilizing available information to conserve hardwood rangeland ecosystems;
- Maintain economically viable private hardwood rangeland enterprises;

- Maintain statewide information base about trend, condition, and extent of hardwood rangelands; and
- Help focus public awareness about the importance of hardwood rangeland habitats.

The Sierra Nevada Ecosystem Project
http://ceres.ca.gov/snep/pubs/web/v1/v1_default.html
Sierra Nevada Ecosystem Study (SNEP) was a congressionally mandated 3 year study of the entire Sierra Nevada range. The study was managed by the University of California Centers for Water and Wildland Resources, Davis, CA under a research agreement with the U. S. Forest Service, Pacific Southwest Research Station, Albany, CA. Posted on the above web site are final reports from this intensive study by an independent science team. Formal release of the report to Congress occurred on June 7, 1996.

Hastings Natural History Reservation
http://www.hastingsreserve.org/OakStory/OakIntro.html
Hastings is a Biological Field Station of the University of California providing the wildlands and facilities to conduct college and graduate level studies of natural systems in the Santa Lucia range in Monterey County, California. Our research reveals that every species has a fascinating story. Their stories put our lives in perspective. We hope that sharing these stories will inspire individuals to protect and appreciate whatever is still wild and under their care.

The Sierra Nevada Framework for Conservation and Collaboration
http://www.r5.fs.fed.us/sncf/
In early 1998, the USDA Forest Service Pacific Southwest Region, the Pacific Southwest Research Station and the Intermountain Region renewed their efforts to work with tribes, county governments, state and federal agencies, interest groups and individuals interested in improving the health of Sierra Nevada ecosystems and communities. The effort integrates recent science into natural resource management through a variety of approaches and at a variety of geographic scales. It also works toward more effective means of coordination, cooperation and collaboration among the various parties.

The Sierra Nevada Forest Plan Amendment Environmental Impact Statement is one of several Framework activities. At this site, you will find links to several other projects and activities going on in the Framework. The Design Paper outlines many of the commitments the Forest Service is making as part of its contribution toward improving natural resource management and collaboration among tribes, agencies, local governments and citizens.

US Department of Agriculture—Natural Resources Conservation Service Programs
While there are a variety of USDA programs available to assist people with their conservation needs, the following primarily financial assistance programs are the principal programs available. Locally led conservation groups are encouraged to contact the State offices of the appropriate agency for specific information about each program.

For more information about any of the following NRCS programs: http://www.nrcs.usda.gov/
Natural Resources Conservation Service
Attn: Conservation Communications Staff
P.O. Box 2890
Washington, DC 20013

Forestry Incentives Program
http://www.nhq.nrcs.usda.gov/CCS/FB96OPA/FBillLnk.html
The 1996 Farm Bill extends the Forestry Incentives Program (FIP), which was originally authorized in 1978 to share up to 65 percent of the costs of tree planting, timber stand improvements, and related practices on non-industrial private forest lands FIP's forest maintenance and reforestation provide numerous natural resource benefits, including reduced wind and soil erosion and enhanced water quality and wildlife habitat as well as helping to assure a reliable future supply of timber. Improving timber stands, which help to sequester greenhouse gases, also contributes to the President's Climate Change initiative. FIP is administered by the U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS) and Forest Service.

Program Availability
FIP is a nationwide program available in counties designated on the basis of a Forest Service survey of total eligible private timber acreage that is potentially suitable for production of timber products. Federal cost-share money is available-with a limit of $10,000 per person per year with the stipulation that no more than 65 percent of the cost may be paid. To find out if your county participates in FIP, check with your local USDA office, State forester, conservation district, or Cooperative Extension office.

The Wildlife Habitat Incentives Program (WHIP)
http://www.nhq.nrcs.usda.gov/PROGRAMS/Animals/whip/index.htm
A voluntary program for people who want to develop and improve wildlife habitat primarily on private lands. It provides both technical assistance and cost-share payments to help establish and improve fish and wildlife habitat.

Participants who own or control land agree to prepare and implement a wildlife habitat development plan. The U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS) offers participants technical and financial assistance for the establishment of wildlife habitat development practices. In addition, if the landowner agrees, cooperating State wildlife agencies and nonprofit or private organizations may provide expertise or additional funding to help complete a project.

Conservation Technical Assistance (CTA)
The purpose of the program is to assist land-users, communities, units of state and local government, and other Federal agencies in planning and implementing conservation systems. The purpose of the conservation systems are to reduce erosion, improve soil and water quality, improve and conserve wetlands, enhance fish and wildlife habitat, improve air quality, improve pasture and range condition, reduce upstream flooding, and improve woodlands.

Conservation Reserve Program (CRP)
The Conservation Reserve Program reduces soil erosion, protects the Nation's ability to produce food and fiber, reduces sedimentation in streams and lakes, improves water quality, establishes wildlife habitat, and enhances forest and wetland resources. It encourages farmers to convert highly erodible cropland or other environmentally sensitive acreage to vegetative cover, such as tame or native grasses, wildlife plantings, trees, filterstrips, or riparian buffers. Farmers receive an annual rental payment for the term of the multi-year contract. Cost sharing is provided to establish the vegetative cover practices.

US Fish and Wildlife Service—Partners for Fish and Wildlife
The mission of the U.S. Fish and Wildlife Service is, by working with others, to conserve, protect, and enhance fish and wildlife and their habitats for the continuing benefit of the American people. The Service's Partners for Fish and Wildlife program, formerly named the Partners for Wildlife program, helps accomplish this mission by offering technical and financial assistance to private (non-federal) landowners to voluntarily restore wetlands and other fish and wildlife habitats on their land. The program emphasizes the reestablishment of native vegetation and ecological communities for the benefit of fish and wildlife in concert with the needs and desires of private landowners.

For more information about any of the following US Fish and Wildlife programs:
http://partners.fws.gov/index.htm

Partners for Fish and Wildlife
State Coordinator
2800 Cottage Way W-2610
Sacramento, CA 95825
916-414-6446

The assistance that the U.S. Fish and Wildlife Service offers to private landowners may take the form of informal advice on the design and location of potential restoration projects, or it may consist of designing and funding restoration projects under a voluntary cooperative agreement with the landowner. Under the cooperative agreements, the landowner agrees to maintain the restoration project as specified in the agreement for a minimum of 10 years.

Restoration projects may include, but are not limited to:
- planting native grasslands and other vegetation

- planting native trees and shrubs in formerly forested wetlands and other habitats
- prescribed burning as a method of removing exotic species and to restore natural disturbance regimes necessary for some species survival
- removal of exotic plants and animals which compete with native fish and wildlife and alter their natural habitats

B. General Information

The Information Center for the Environment, at *http://ice.ucdavis.edu/* is a cooperative effort of environmental scientists at the University of California, Davis and collaborators at over thirty private, state, federal, and international organizations interested in environmental protection. Within this site, find the California Ecological Restoration Projects Inventory (CERPI) (direct link: **http://endeavor.des.ucdavis.edu/cerpi/**) and the California Noxious Weeds Projects Inventory (CNWCPI). (direct link: **http://endeavor.des.ucdavis.edu/weeds/**)

CERPI is a combined private/non-profit/government effort to establish a database, accessible through the Internet, containing information on restoration projects in California. This information will further the practice and science of restoration and assist agencies and practitioners during restoration planning and implementation.
CNWCPI is a combined government/private/non-profit effort to establish a database, accessible through the Internet, containing information on noxious weed control in California. This information will further the practice and science of noxious weed control and assist agencies and practitioners doing noxious weed control throughout the state. CERPI and CNWCPI are both programs of the Natural Resource Projects Inventory (NRPI)

The California Environmental Resources Evaluation System
http://www.ceres.ca.gov/index.html
CERES is an information system developed by the California Resources Agency to facilitate access to a variety of electronic data describing California's rich and diverse environments. The goal of CERES is to improve environmental analysis and planning by integrating natural and cultural resource information from multiple contributors and by making it available and useful to a wide variety of users.

California Wildlife Habitat Relationships, at *http://www.dfg.ca.gov/whdab/*
California Wildlife Habitat Relationships (CWHR) is a state-of-the-art information system for California's wildlife. CWHR contains life history, management, and habitat relationships information on 675 species of amphibians, reptiles, birds, and mammals known to occur in the state. CWHR products are available to purchase by anyone interested in understanding, conserving, and managing California's wildlife (Mayer and Laudenslayer 1988).

A Manual of California Vegetation (Sawyer and Keeler-Wolf) on line at *http://endeavor.des.ucdavis.edu/cnps/*

Forest Service Technical Reports can be ordered from 970-498-1392.

Appendix B. How to Monitor Bird Populations

Adaptive management requires the periodical gathering of information to ascertain whether management actions are achieving desired results. The most comprehensive and rigorous way of collecting this information is through a strategic program of monitoring using standardized methods that can be compared between years and between regions. Restoration and land stewardship programs need to build in long-term monitoring programs to assess the effectiveness of their activities. Without such data in the long term, such programs will ultimately have little on which to base claims of success or the need for continued funding.

Research and Monitoring

If habitat restoration or management is undertaken to benefit wildlife species, wildlife monitoring becomes the ultimate measure of success. There are many reasons that bird monitoring should be adopted as a basic component of long-term stewardship in preserves with significant habitats or significant bird populations:

- Birds are highly visible and cost effective to monitor.
- Birds can show relatively quick response in abundance and diversity to restored habitats (3 to 5 years).
- Birds can serve as indicators for key components of ecosystem health, such as acorn productivity, oak age structure, and understory vegetation composition.
- As secondary consumers (i.e., insectivores), birds are sensitive indicators of environmental change.
- By managing for a diversity of birds, most other elements of biodiversity are conserved.
- Bird monitoring can avoid future listing of declining species by identifying problems and solutions early.
- The only way to measure special-status bird species response to management and restoration is by monitoring bird populations.
- Because of the increasing popularity of birdwatching, there is great potential for public participation in bird monitoring.
- Birds are tremendously important culturally and economically and their popularity can help raise awareness of land-stewardship needs.

Monitoring Strategically

Monitoring can be conducted at varying levels of intensity, depending on the objectives to be achieved and the resources available. The standardization of protocols is critical to comparing results across space and time. Many recent programs (Ralph et al. 1995, Martin et al. 1997, DeSante et al. 1999a) and publications (Ralph et al. 1993, Geupel and Warkentin 1995, DeSante et al. 1995, 1998, 1999b, Nur et al. 1999) have summarized methods, objectives, and how to use results.

Monitoring programs should always include an analysis plan and identification of issues or site-specific projects to be assessed. The primary purpose of site-specific monitoring is to assess the effects on wildlife of natural and anthropogenic stressors or disturbances in the environment. This knowledge is critical in determining the relative priority of identified conservation problems and in developing effective measures to address those problems. Monitoring is an integral component of the adaptive management feedback loop, allowing land managers, conservation groups, and land owners to assess the effectiveness of their habitat management and restoration programs.

Standardized monitoring across many sites at varying scales can be analyzed to highlight broad changes or trends in species presence, diversity, abundance and productivity. Ideally, a series of reference sites with long-term monitoring, using most if not all protocols below, will be developed for each California bioregion. Other sites will be monitored more opportunistically, depending on the objectives of the landowner.

The following is a list of common monitoring regimes from least to most intensive.

1) Rapid assessment of habitat or designation of Important Bird Areas based on general vegetation characteristics and presence/absence of indicator species.
Method: area search or point count as little as one census per site per year.

2) Determine breeding status, habitat association, restoration evaluation and/or evaluation of changes in management practices.
Method: area search or point count two or more times per year for 3 years. For restoration evaluation every other year, censusing should continue for at least 10 years.

3) Determination of population health or source/sink status.
Method: census combined with demographic monitoring for a minimum of 3 years (4 years preferable).

4) Reference site.
Method: point count census, constant effort mist netting and nest monitoring at a minimum of every other year for 10 years.

Long-term Monitoring

Long-term monitoring provides a wealth of useful information about bird populations. In addition to parameters that can be determined by both short- and long-term monitoring (such as annual productivity, abundance, and diversity), patterns of variation in reproductive success and trends in abundance and diversity may also be described. Long-term monitoring is also the only method to monitor natural and human-induced changes in bird populations.

The Palomarin Field Station of the Point Reyes Bird Observatory provides an excellent example of the utility of a long-term monitoring program. Biologists have conducted mist-netting at the site for over twenty years. With the data collected, they have documented a population decline of Warbling Vireos and linked it to reproductive failure on the breeding grounds (Gardali et al. 2000).

Standardized Methods Adopted by the Western Working Group and Monitoring Working Group of Partners in Flight

These are listed from least to most intensity of effort. All are described in detail in Handbook of Field Methods for Monitoring Landbirds (Ralph et al. 1993).

Area Search

The Area Search, adopted from the Australian Bird Count, is a habitat specific, time constraint census method to measure relative abundance and species composition. It may also provide breeding status. While still quantitative, this technique is ideal for volunteers as it mimics the method that a birder would use while searching for birds in a given area, allowing the observer to track down unfamiliar birds.

Point Count

The point count method is used to monitor population changes of breeding landbirds. With this method, it is possible to study the yearly changes of bird populations at fixed points and differences in species composition between habitats and assess breeding status and abundance patterns of species. The objective of point count vegetation assessment is to relate the changes in bird composition and abundance to differences in vegetation. These vegetation changes can either be over time or differences between habitats or study sites.

Mist Netting

Mist netting provides insight into the health and demographics of the population of birds being studied. Mist nets provide valuable information on productivity, survivorship, and recruitment. With these data, managers will have information on the possible causes of landbird declines or their remedies. This method is currently being used nationwide in the Monitoring Avian Productivity and Survivorship (MAPS) program (DeSante 1992).

Territory Mapping

Also known as "spot mapping," based on the territorial behavior of birds, where locations of birds are marked on a detailed map during several visits (a minimum of eight) in the breeding

season. By counting the number of territories in an area, this method estimates the density of birds. Distribution of territories, species richness, and diversity is also documented. This is an excellent method for assessing areas with limited habitat. Standard methods are described by Robbins (1970) and used by The Cornell Laboratory of Ornithology's resident bird counts.

Nest Monitoring

Also called nest searching, this technique measures nesting success in specific habitats and provides information on trends in recruitment; measurement of vegetation associated with nests may identify habitat influences on breeding productivity. Examination of nests also allows collection of life-history data (e.g., clutch size, number of broods, numbers of nesting attempts), which provide important insight into vulnerability of species to decimation or perturbations (Martin and Geupel 1993).

Cover rendering and photo this page: The new Bridge for Laboratory Sciences building at Vassar College, designed by Richard Olcott/Ennead Architects, redefines the identity of the sciences on the College's historic campus and provides technologically advanced facilities for students, faculty, and researchers.

Fundamental to the building's design is its seamless integration with the natural landscape, scale, and campus aesthetic of the College. In this natural wooded setting, the need for strategies to reduce bird collisions with the building was apparent. In response, the building was designed to comply with LEED Pilot Credit 55: Bird Collision Deterrence.

Ennead managing partner Guy Maxwell is a nationally recognized champion of bird-friendly design and has led Ennead's innovative approach to make the building's glazing safer for birds, employing patterned glass, screens and sunshades, and Ornilux glass, a specialty glass product that uses a UV coating visible to birds but not humans.

By framing and showcasing views of the landscape, the building celebrates and connects students with the surrounding environment, while the overall development of the precinct repurposes an underutilized sector of campus.

Executive Summary

A bird, probably a dove, hit the window of an Indiana home hard enough to leave this ghostly image on the glass. Photo by David Fancher

Collision with glass claims the lives of hundreds of millions of birds each year in the United States. It is second only to domestic cats as a source of mortality linked directly to human action. Birds that have successfully flown thousands of miles on migration can die in seconds on a pane of glass; impacts kill fledglings before they can truly fly. Because glass is dangerous for strong, healthy, breeding adults, as well as sick or young birds, it can have a particularly serious impact on populations.

Bird kills occur at buildings across the United States and around the world. We know most about mortality patterns in cities, because that is where most monitoring takes place, but virtually any building with glass poses a threat wherever it is. The dead birds documented by monitoring programs or provided to museums constitute merely a fraction of the birds actually killed. The magnitude of this problem can be discouraging, but there are already effective solutions and an increasing commercial commitment to developing new solutions, if people can be convinced to adopt them.

That artificial lighting at night plays a significant part in mortality from glass is widely accepted, but often misunderstood. The majority of collisions with buildings take place during daylight. There are many well-documented instances of bright lights at night disorienting large numbers of birds—usually night-migrating passerines but also seabirds—some of which may circle in the light, sometimes until dawn. Nocturnal mortality associated with circulation events is caused by collision with guy wires and other structures. Such events were described starting in the late 19th century at lighthouses, and later at the Washington Monument, Statue of Liberty, and Empire State Building, which were the only brightly lit structures in their areas. Today, such events occur mostly at offshore drilling platforms and communication towers. These situations have in common bright light surrounded by darkness, and their frequency has decreased in cities as areas of darkness around bright structures have also become lit. However, there are strong indications that birds are still being disoriented by urban lights and that lights are linked to mortality, even though mortality patterns have changed.

Advances in glass technology and production since the mid-twentieth century have made it possible to construct skyscrapers with all-glass walls, homes with huge picture windows, and miles of transparent noise-barriers on highways. There has been a general increase in the amount of glass used in construction—and the amount of glass on a building is the best predictor of

Newhouse III, designed by Polshek Partnership Architects, is part of Syracuse University's S.I. Newhouse School of Public Communications. the number of birds it will kill. However, while glass is important for bringing light into buildings, a façade with over 30-40% glass dramatically increases energy use for heating and cooling. Bird-friendly design is becoming recognized as part of sustainable design, required increasingly by legislation across North America.

New construction can incorporate from the beginning bird-friendly design strategies that are cost neutral. There are many ways to reduce mortality from existing buildings, with more solutions being developed all the time. Because the science is constantly evolving, and because we will always wish for more information than we have, the temptation is to postpone action in the hope that a panacea is just around the corner. But we can't wait to act. We have the tools and the strategies to make a difference now. Architects, designers, city planners, and legislators are key to solving this problem. They not only have access to the latest building construction materials and concepts; they are also thought leaders and trend setters in the way we build our communities and prioritize building design issues.

The steel mesh enveloping Zurich's Cocoon in Switzerland, designed by Camenzind Evolution, Ltd, provides privacy, reduces heating and cooling costs, and protects birds, but still permits occupants to see out. Photo by Anton Volgger

This publication aims to provide planners, architects, and designers, bird advocates, and local, municipal, and federal authorities, as well as the general public, with a clear understanding of the nature and magnitude of the threat glass poses to birds. Since the first edition, in 2011, there has been increased awareness of collisions, evidenced by new ordinances and guidelines for bird-friendly construction, new materials to retrofit existing buildings, and promotion by the glass industry of bird-friendly materials.

This edition includes an updated review of the underlying science, examples of solutions that can be applied to both new construction and existing buildings, and an explanation of what information is still needed. We hope it will spur individuals, businesses, communities, scientists, and governments to address this issue and make their buildings safer for birds. Constructing bird-friendly buildings and eliminating the worst existing threats require only imaginative design, effective retrofits, and recognition that birds have intrinsic and cultural as well as economic and ecological value to humanity.

American Bird Conservancy's Collisions Program works at the national level to reduce bird mortality by coordinating with organizations and governments, developing educational programs and tools, evaluating and developing solutions, creating centralized resources, and generating awareness.

INTRODUCTION

Why Birds Matter

For many people, birds and nature have intrinsic worth. Birds have been important to humans throughout history, often symbolizing cultural values such as peace, freedom, and fidelity. In addition to the pleasure they can bring to people, we depend on them for critical ecological functions. Birds consume vast quantities of insects and control rodent populations, reducing damage to crops and forests and helping limit the transmission of diseases such as West Nile virus, dengue fever, and malaria. Birds play a vital role in regenerating habitats by pollinating plants and dispersing seeds. Birds are also a direct economic resource. According to the U.S. Fish and Wildlife Service, bird watching is one of the fastest growing leisure activities in North America, an over $40 billion industry accounting for many jobs.

The Legal Landscape

At the start of the 20th century, following the extinction of the Passenger Pigeon and the near extinction of other bird species due to unregulated hunting, laws were passed to protect bird populations. Among them was the Migratory Bird Treaty Act (MBTA), which made it illegal to kill a migratory bird without a permit. The scope of this law, which is still in effect today, extends beyond hunting, such that anyone causing the death of a migratory bird, even if unintentionally, can be prosecuted if that death is deemed to have been foreseeable. At present, the scope of the MBTA is under challenge in federal court and it is impossible to say whether it will ever be used to curb glass collisions. However, courts in Canada have ruled that building owners are responsible for mortality caused by glass.

Violations of the MBTA can result in fines of up to $500 per incident and up to six months in prison. The Bald and Golden Eagle Protection Act (originally the Bald Eagle Protection Act of 1940), the Endangered Species Act (1973), and the Wild Bird Conservation Act (1992) provide further protections for birds that may apply to building collisions. Recent legislation, primarily at the city and state levels, has addressed the problem of mortality from building collisions and light pollution. Starting with Toronto, Canada, in 2009 and San Francisco, California, in 2010 an increasing number of states and municipalities have passed laws mandating bird-friendly design, while other authorities have passed voluntary measures.

Glass: The Invisible Threat

Glass is invisible to both birds and humans. Humans learn to see glass through a combination of experience and visual cues like mullions and even dirt, but birds are unable to use these signals. Most birds' first encounters with glass are fatal when they collide with it at full flight speed. Aspects of bird vision contribute to the problem. Whereas humans have eyes in the front of their heads and good depth perception, most birds' eyes are placed at the sides of their heads. Birds thus have little depth perception beyond the range of their bills but extensive fields of view to the side and behind. They judge their flight speed by the passing of objects to their sides, so their focus in flight is not necessarily ahead. Besides simply using designs with less glass, we can protect birds by using screens, shutters, and details that partly obscure glass while still providing a view, or by using two-dimensional patterns that birds perceive as actual barriers. However, birds have poor contrast sensitivity compared to humans: shapes at a distance merge into a blur at closer range for birds. This means that most signals that make glass safe for birds will probably be readily visible to people.

Reflections on home windows are a significant source of bird mortality. The partially opened vertical blinds here may break up the reflection enough to reduce the hazard to birds. Photo by Christine Sheppard, ABC

Birds may try to reach vegetation seen through two or more glass walls or windows; the single decal here is not enough to solve the problem, but two or three could do the trick. Photo by Christine Sheppard, ABC

Lighting: Exacerbating the Threat

Most birds, with obvious exceptions, are active by day, with eyes best adapted for daylight sight. However, many bird species migrate by night, allowing them to use daylight hours for feeding. We still don't know everything about how night-flying birds navigate. We do know that birds probably have two special senses that allow them to determine location and direction using the Earth's magnetic field. One of these, located in the eye, may allow birds to "see" magnetic lines in the presence of dim blue light. Star maps, landmarks, and other mechanisms are also involved.

Artificial night lighting seemingly disrupts orientation mechanisms evolved to work with dimmer, natural light sources and can cause birds to deviate from their flight paths. The problem is compounded for birds flying in mist or cloud, which can cause them to fly lower and closer to artificial light sources, depriving them of celestial and magnetic cues. As birds fly near light sources, they may become disoriented and eventually land in the built environment.

Light at night can disorient birds, and the problem is not restricted to tall buildings. This scene of Las Vegas by night depicts a threat to any bird migrating nearby at night. Photo by BrendelSignature, Wikipedia

The majority of collisions with buildings actually take place by day. As birds seek food to fuel their next migratory flight, they face a maze of structures, and many, unable to distinguish between habitat and reflections, hit glass. The amount of light emitted by a building is a strong predictor of the number of collisions it will cause, more so than building height. Patterns of light intensity across a nocturnal landscape may influence the pattern of birds landing in that landscape at the end of migration stages. Thus, reducing light trespass from all levels of buildings and their surroundings is an important part of a strategy to reduce collisions with glass. There is some recent evidence that electromagnetic radiation outside the visible spectrum may also disorient birds.

Birds and the Built Environment

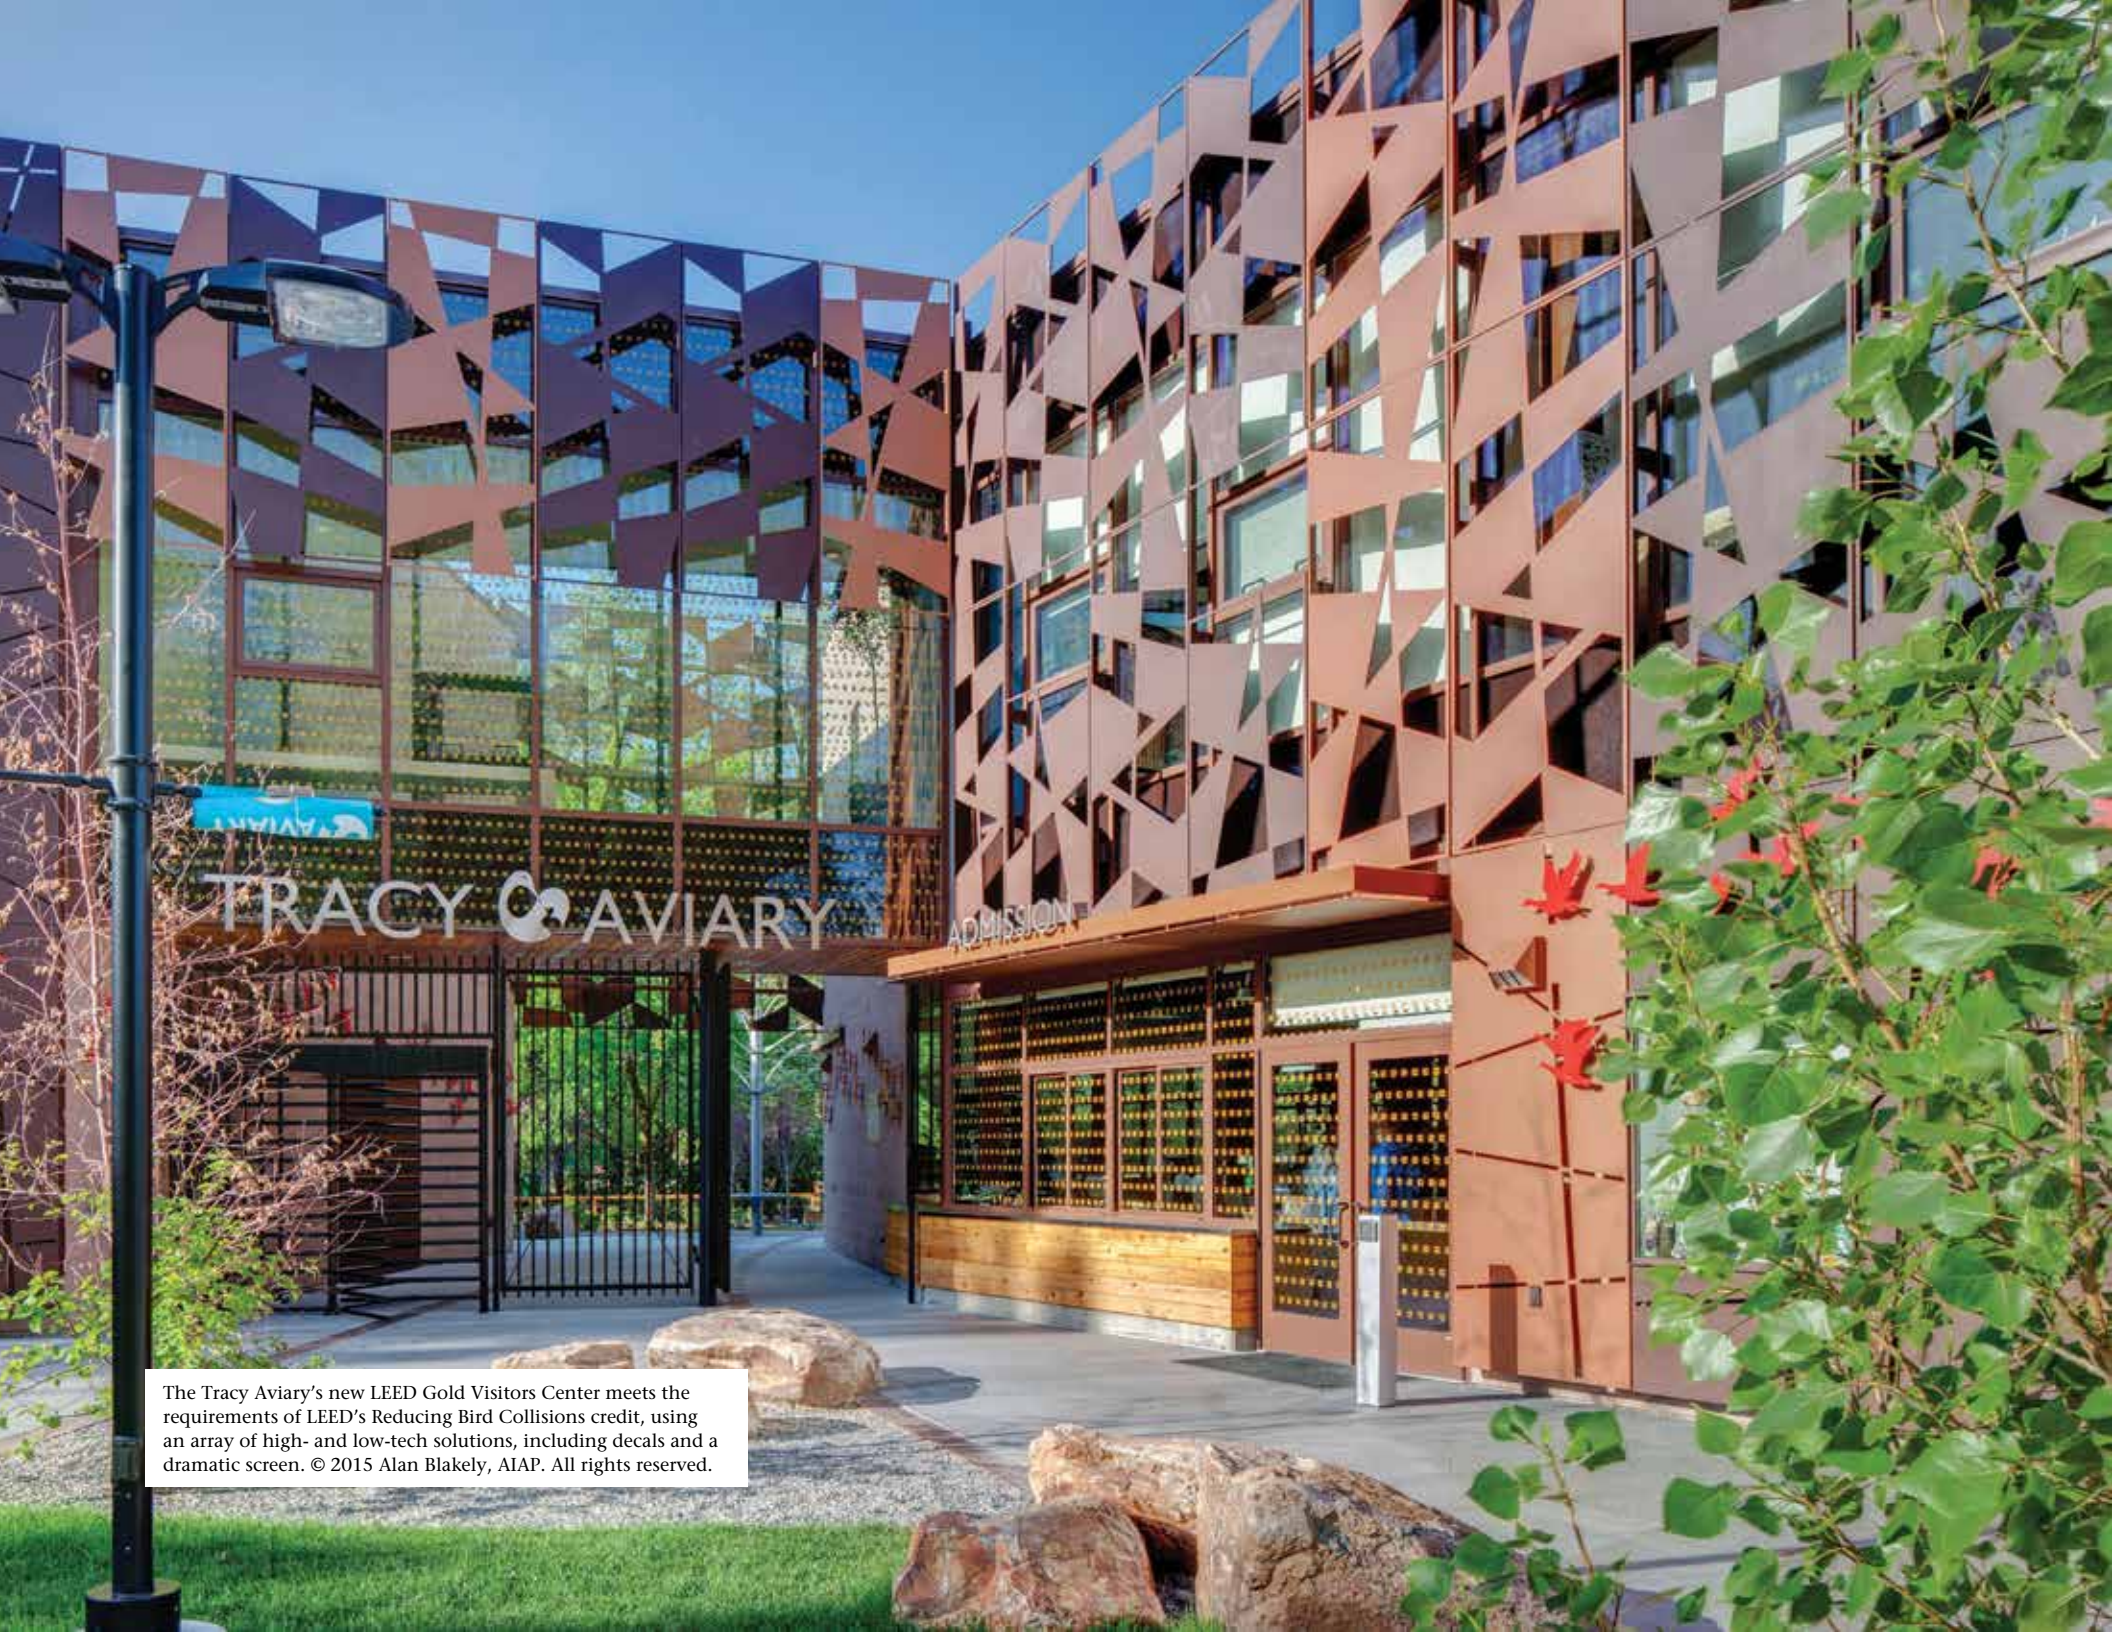
Humans first began using glass in Egypt around 3500 BCE. Glass blowing, invented by the Romans in the early first century CE, greatly increased the ways glass could be used, including the first crude glass windows. The 17th century saw the development of the float process, enabling production of large sheets of glass. This technology became more sophisticated, eventually making glass windows available on a large scale by the 1960s. In the 1980s, development of new production and construction technologies culminated in today's glass skyscrapers and increasing use of glass in all types of construction.

Sprawling land-use patterns and intensified urbanization degrade the quality and quantity of bird habitat across

the globe. Cities and towns encroach on riverbanks and shorelines. Suburbs, farms, and recreation areas increasingly infringe upon wetlands and woodlands. Some bird species simply abandon disturbed habitat. For resident species that can tolerate disturbance, glass is a constant threat, as these birds are seldom far from human structures. Migrating birds are often forced to land in trees lining our sidewalks, city parks, waterfront business districts, and other urban green patches that have replaced their traditional stopover sites.

The amount of glass in a building is the strongest predictor of how dangerous it is to birds. However, even small areas of glass can be lethal. While bird kills at homes are estimated at one to 10 birds per home per year, the large number of homes multiplies that loss to millions of birds per year in the United States, representing over 46% of the total problem. Other factors can increase or decrease a building's impact, including the density and species composition of local bird populations; local geography; the type, location, and extent of landscaping and nearby habitat; prevailing wind and weather; and patterns of migration through the area. All must be considered when planning bird-friendly buildings.

Impact of Collisions on Bird Populations



About 25% of species are now on the U.S. Watch List of birds of conservation concern (abcbirds.org/birds/watchlist/), and even many common species are in decline. Habitat destruction or alteration of both breeding and wintering grounds remains the most serious man-made problem, but collisions with buildings are second only to domestic cats as direct fatality threats. Nearly one-third of the bird species found in the United States—more than 258 species, from hummingbirds to falcons—are documented as victims of collisions. Unlike natural hazards that predominantly kill weaker individuals, collisions kill all categories of birds, including some of the strongest, healthiest birds that would otherwise survive to produce offspring. Without action, the cumulative effect of these deaths will result in significant population declines. Most of the mortality is avoidable. This document is one piece of a strategy to keep building collisions from increasing and, ultimately, to reduce them.

Bird Collisions and Sustainable Architecture

In recent decades, advances in glass technology and production have made it possible to construct tall buildings with all-glass walls, and we have seen a general increase in the amount of glass used in all types of construction. This is manifest in an increase in picture windows in private homes, glass balconies and railings, bus shelters, and gazebos. New applications for glass are being developed all the time. Unfortunately, as the amount of glass increases, so does the incidence of bird collisions.

The Cape May campus of Atlantic Cape Community College inherited a building with large areas of glass that did not have coatings or film to control temperature and glare—and there were many collisions. The addition of Collidescape has eliminated the threat to birds while reducing heating and cooling costs. Photo by Lisa Apel-Gendron

In recent decades, growing concern for the environment has stimulated the creation of "green" standards and rating systems for development. The best known is the U.S. Green Building Council (USGBC) Leadership in Energy and Environmental Design, or LEED. While the USGBC concurred that sustainable buildings should not kill birds, it was initially difficult to create recommendations within the LEED credit system. The solution was based on a technique called "tunnel testing," a non-lethal method using live birds that permits a relative threat score to be assigned to patterned glass and other materials. (The section on Research in Chapter 6 reviews the work underlying the assignment of threat scores.)

On October 14, 2011, USGBC added Pilot Credit 55: Bird Collision Deterrence to its Pilot Credit Library. The credit was drafted by American Bird Conservancy (ABC), members of the Bird-Safe Glass Foundation, and the USGBC Site Subcommittee. Building developers that wish to earn this credit must quantify the threat level to birds posed by various materials and design details. These threat factors are used to calculate an index, or weighted average, representing the building's façade; that index must be below a standard value to earn the credit. The index is intended to provide wide latitude in creating designs that meet the criteria. The credit also requires adopting interior and exterior lighting plans and post-construction monitoring.

Pilot Credit 55 has been the most widely used credit in the pilot library. A revised version of the credit, posted in the fall of 2015, expands its availability to all LEED rating systems except "neighborhoods."

ABC is a registered provider of the American Institute of Architects (AIA) Continuing Education System, offering classes on bird-friendly design and LEED Pilot Credit 55 in face-to-face and webinar formats. Contact Christine Sheppard, csheppard@abcbirds.org, for more information.

Defining What's Good for Birds

It is increasingly common to see the term "bird-friendly" used in a variety of situations to demonstrate that a particular product, building, legislation, etc., is not harmful to birds. All too often, however, this term is unaccompanied by a clear definition and lacks a sound scientific foundation to underpin its use. Ultimately, defining "bird-friendly" is a subjective task. Is bird-friendliness a continuum, and if so, where does friendly become unfriendly? Is "bird-friendly" the same as "bird-safe?" How does the definition change from use to use, situation to situation? It is impossible to know exactly how many birds a particular building will kill before it is built, and so, realistically, we cannot declare a building to be bird-friendly before it has been carefully monitored for several years.

There are factors that can help us predict whether a building will be particularly harmful to birds or generally benign, and we can accordingly define simple "bird-friendly building standards" that, if followed, significantly reduce potential hazard to birds. That said, a 75% reduction of mortality at a structure that kills 400 birds a year means that structure will still kill 100 birds a year. Because window kills affect reproductively active adult birds, the cumulative effect of saving some birds is amplified by their reproductive output. Because a 100% reduction in mortality may be difficult to achieve, ABC takes the position that it is better to take reasonable available actions immediately than to put off taking action until a perfect solution is possible or to take no action at all.

Problem: Glass

The glass in this Washington, D.C., atrium poses a double hazard, drawing birds to plants inside as well as reflecting sky above. Photo by Christine Sheppard, ABC

Properties of Glass

Glass, as a structural material, can range in appearance from transparent to mirrored to opaque. Its surface can completely reflect light or let virtually 100% of light pass through. A particular piece of glass will change appearance depending on environmental factors, including position relative to the sun, the difference between exterior and interior light levels, what may be reflected, and the angle at which it is viewed. Combinations of these factors can cause glass to look like a mirror or a dark passageway, or be completely invisible. Humans do not actually "see" clear glass, but are cued by context such as mullions, dirt, or window frames. Birds, however, do not perceive right angles and other architectural signals as indicators of obstacles or artificial environments: they take what they see literally. While local birds may become familiar with individual pieces of glass, they do not ever grasp the concept "glass."

The glass-walled towers of the Time Warner Center in New York City appear to birds as just another piece of the sky. Photo by Christine Sheppard, ABC

Reflection

Under the right conditions, even transparent glass on buildings can form a mirror, reflecting sky, clouds, or nearby habitat attractive to birds. When birds try to fly to the reflected habitat, they hit the glass. Reflected vegetation is the most dangerous, but birds also attempt to fly past reflected buildings or through reflected passageways, with fatal results.

Transparency

Birds strike transparent windows as they attempt to access potential perches, plants, food or water sources, or other lures seen through the glass, whether inside or outside. Large planted atria are frequent problems, as are glass balcony railings and "skywalks" joining buildings. The increasing trend toward glass used in landscapes, as walls around roof gardens, as handrails or walkway dividers and even gazebos is dangerous because birds perceive an unobstructed route through them to habitat beyond.

Black Hole or Passage Effect

Birds often fly through small gaps, such as spaces between leaves or branches, into nest cavities, or through other small openings that they encounter. In some light, the space behind glass can appear black, creating the appearance of just such a cavity or "passage" with unobstructed access through which birds try to fly.

Transparent handrails are a dangerous trend for birds, especially when they front vegetation. Photo by Christine Sheppard, ABC

Large facing panes of glass can appear to be a clear pathway. Photo by Christine Sheppard, ABC

The same glass can appear transparent or highly reflective, depending on weather or time of day.

Factors Affecting Rates of Bird Collisions for a Particular Building

Every site and every building can be characterized as a unique combination of risk factors for collisions. Some of these, particularly aspects of a building's design, are very building-specific. Many problem design features can be readily improved, or, in new construction, avoided. Others of these—for example, a building's location relative to migration stopover sites, regional ecology, and geography—are difficult if not impossible to modify.

Building Design

People like glass and it has become a popular building material. All-glass buildings have become more and more common as glass has become a low-cost material for construction. Glass causes virtually all bird collisions with buildings. Studies based on monitoring data have shown a direct relationship between the amount of glass on a building and the number of collisions at that site—the more glass, the more bird deaths.

Mirrored glass is often used intentionally to make a building "blend" into a vegetated area by reflecting its surroundings, making those buildings especially deadly to birds. However, all-glass buildings are coming increasingly into question. According to groups like the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) and the International Code Council, when there is more than 30-40% glass on a façade, heating and cooling costs begin to increase.

Building Size

Glass skyscrapers, because of their height and visibility, are often the main focus of collision documentation, and they do account for more collisions per building than smaller structures. However, because there are many more homes and low-rise buildings, the latter account for more total mortality. A study published by scientists at the Smithsonian in 2014 estimated 508,000 annual bird deaths for high-rises, 339 million for low-rises, and 253 million for homes. More collisions probably occur at glass on lower floors, where most bird activity takes place, but when monitors have had access to setbacks and roofs, they have consistently found at least some carcasses, indicating that glass at any level can be a threat.

Orientation and Siting

Because migrating birds are frequent collision victims, it is often assumed that more collisions will occur on north- and south-facing façades. However, most building collisions take place during the day, and building orientation in relation to compass direction has not been implicated as a factor. Siting of buildings with respect to surrounding habitat and landscaping has more

Birds flying from a meadow on the left are channeled toward the glass doors of this building by a rocky outcrop to the right of the path. Photo by Christine Sheppard, ABC

Mirrored glass is dangerous at all times of day, whether it reflects vegetation, sky, or simply open space through which a bird might try to fly. Photo by Christine Sheppard, ABC

Plantings on setbacks and rooftops can attract birds to glass they might otherwise avoid. Chris Sheppard, ABC

implications. Physical features like walkways that provide an open flight path through vegetated landscape, or obstacles like outcrops of rock or berms, can channel birds toward or away from glass and should be considered early in the design phase. Movement patterns of birds within surrounding habitat may cause unanticipated collisions. Birds often fly between landscape features, for example, between two stands of trees, and may be at risk from structures along their route.

Glass that reflects shrubs and trees causes more collisions than glass that reflects pavement or grass. Studies that measured vegetation within only 15 to 50 feet of a façade have led to the misconception that plantings beyond a certain distance don't influence collisions, but vegetation at much greater distances can easily be visible in reflections. Vegetation around buildings will bring more birds into the vicinity of the building; the reflection of that vegetation brings more birds into the glass. Taller trees and shrubs correlate with more collisions. It should be kept in mind that vegetation on slopes near a building will reflect in windows above ground level. Studies using bird feeders (Klem *et al*. 1991) have shown that fatal collisions result when birds fly toward glass from more than a few feet away.

Time of Day

Collisions tend to happen most when birds are most active. Many studies have documented that although collisions peak during the early morning, they can happen at almost any time of day. Most monitoring programs have focused on early morning before cleaning crews have swept sidewalks because of the increased likelihood of finding birds and because it is easier to obtain volunteer searchers in the pre-work hours.

Green Roofs and Walls

Green roofs bring elements attractive to birds to higher levels, but often they are built in close proximity to glass. However, recent work shows that well-designed green roofs can become functional ecosystems, providing food and even nest sites for birds. Siting of green roofs, as well as green walls and rooftop gardens, should therefore be carefully considered, and glass adjacent to these features should have protection for birds.

Green roofs and walls can provide food and other resources to birds, but they can also attract birds to glass that they might not otherwise encounter. Emilio Ambasz's ACROS building in Fukuoka, Japan, is an interesting example. Photo by Kenta Mobuchi

This atrium has more plants than anywhere nearby on surrounding streets, making the glass deadly for birds seeking food or shelter in this area. Photo by Christine Sheppard, ABC

Solutions: Glass

It is possible to design buildings that can reasonably be expected to kill few or no birds. Numerous examples already exist, not necessarily designed with birds in mind but simply to be functional and attractive. These buildings may have many windows, but their screens, latticework, louvers, and other devices outside, or patterns integrated into the glass, warn birds before they collide. Finding glass treatments that can eliminate or greatly reduce bird mortality, while minimally obscuring the glass itself, has been the goal of several researchers, including Martin Rössler, Daniel Klem, and Christine Sheppard. Their work, discussed in more detail in the Science chapter, has focused primarily on the spacing, length, width, opacity, color, and orientation of elements marked on glass, and has shown that patterns covering as little as 5% of the total glass surface can deter most strikes under experimental conditions. They have shown that as a general rule, most songbirds will not attempt to fly through horizontal spaces less than 2 inches high or through vertical spaces 4 inches wide or less. We refer to this as the 2 x 4 rule, and it is clearly related to the size and shape of birds in flight. (See chart on page 47).

Designing a new structure to be bird-friendly does not require restricting the imagination or adding to the cost of construction. Architects around the globe have created fascinating and important structures that incorporate little or no dangerous glass. In some cases, inspiration has been borne out of functional needs, such as shading in hot climates; in others, from aesthetics. Being bird-friendly usually has been incidental. Now, however, buildings are being designed with birds in mind, and materials designed for this purpose are multiplying. Until recently, retrofitting existing buildings has been more difficult and costly than it is today. However, new materials are appearing and costs can be controlled by targeting problem areas rather than entire buildings.

Bird-friendly materials and design features often overlap in function with materials to control heat and light, security measures, and decorative design details. Bird-friendly building-design strategies also fall into three general categories, although all three could be combined in a single structure. These are:

1. Using minimal glass (Bronx Call Center, U.S. Mission to the United Nations)
2. Placing glass behind some type of screening (de Young Museum, Cooper Union)
3. Using glass with inherent properties that reduce collisions (Brooklyn Botanic Garden Visitors Center; Student Center at Ryerson University, Toronto; and Cathedral of Christ the Light)

Netting, Screens, Grilles, Shutters, Exterior Shades

There are many ways to combine the benefits of glass with bird-friendly design by incorporating elements that preclude collisions while providing light and views. Some architects have designed decorative façades that wrap entire structures. Decorative grilles are also part of many architectural traditions. Exterior, motorized solar screens and shades are effective at controlling heat and light, increase security, and can be adjusted to maximize view or bird and sun protection at different times. Netting, grilles, and shutters are common elements that can make glass safe for birds on buildings of any scale. They can be used in retrofit or be an integral part of an original design and can significantly reduce bird mortality.

The Brooklyn Botanic Garden's Visitors Center, designed by Weiss/Manfredi, was intended to be bird-friendly from its inception—a challenge, as it makes extensive use of glass. Photo @ Alber Vecerka, ESTO

Glass walls and doors at the Brooklyn Botanic Garden's Visitors Center include a custom fritting pattern that meets bird-friendly criteria. Monitoring for collisions after the building opened indicates that the design was successful. Photo by Christine Sheppard, ABC

Overhangs block viewing of glass from some angles, but do not necessarily eliminate reflections. Photo by Christine Sheppard, ABC

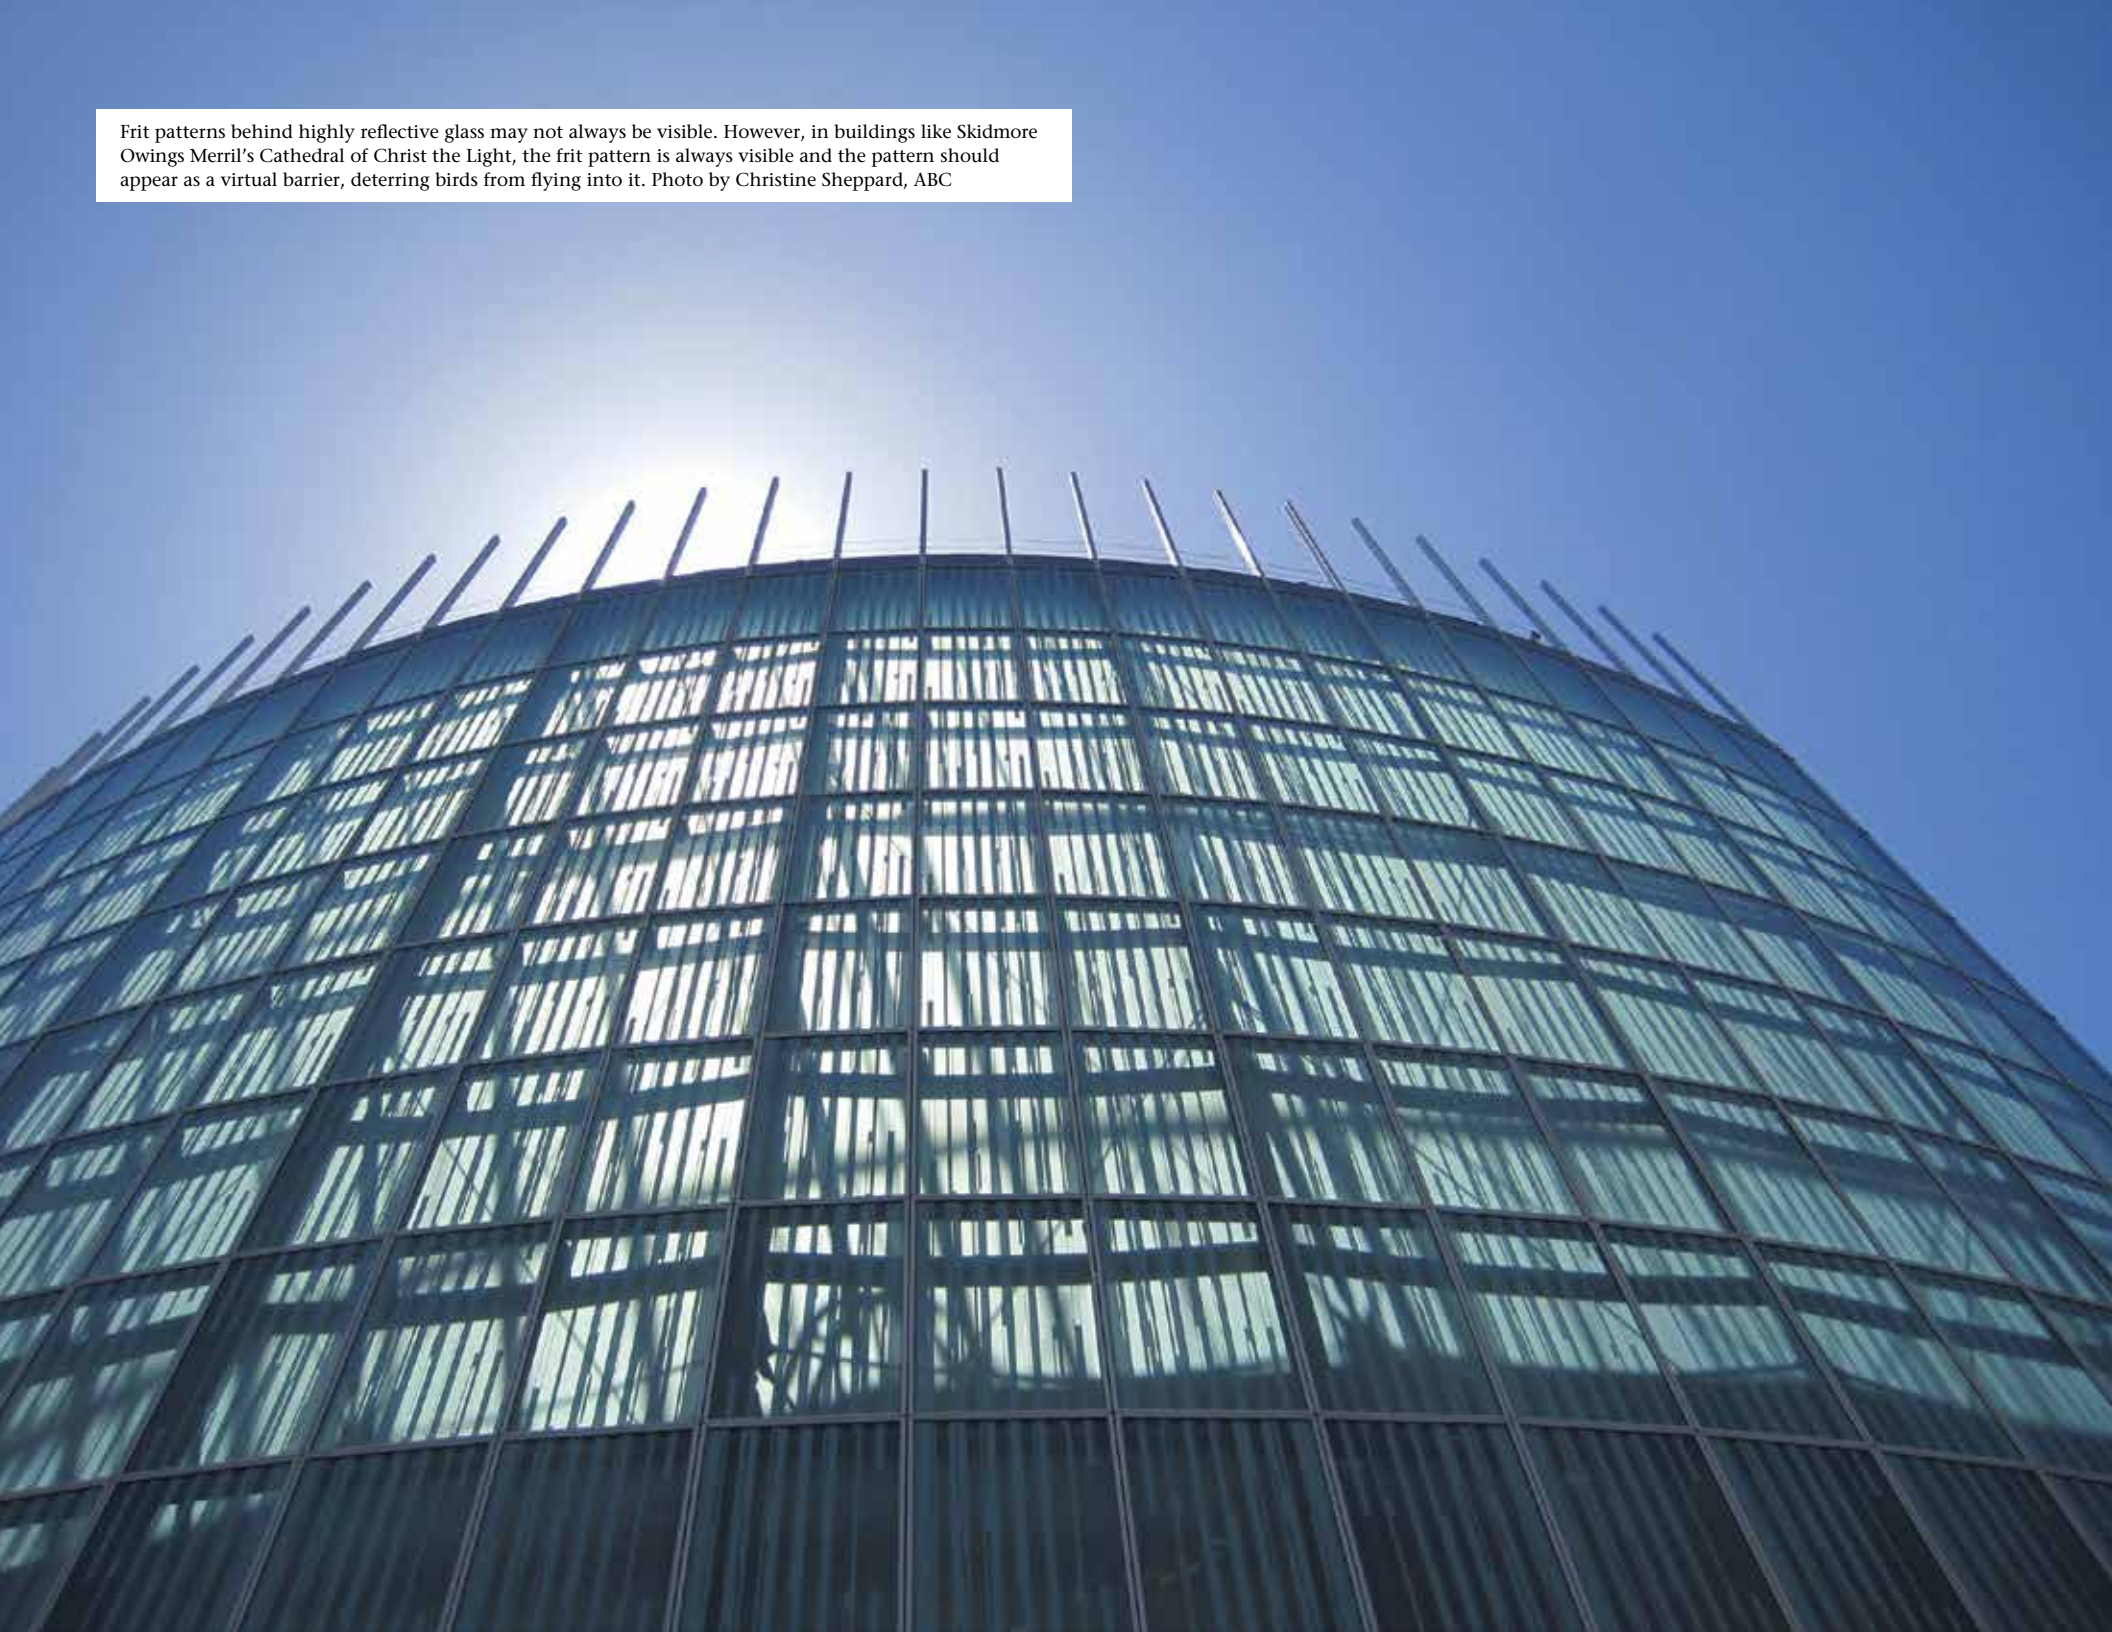
Reflections in this angled façade can be seen clearly over a long distance, and birds can approach the glass from any angle. Photo by Christine Sheppard, ABC

Before the current age of unopenable windows, screens protected birds in addition to serving their primary purpose of keeping bugs out. Screens are still among the most cost-effective methods for protecting birds, and, if insects are not an issue, nearly invisible netting can often be installed. Screens and netting should be installed at some remove from the window so that the impact of a strike does not carry birds into the glass. Several companies sell screens that can be attached with suction cups or eye hooks for small areas of glass. Others specialize in much larger installations. (Find sources at collisions.abcbirds.org).

Awnings and Overhangs

Overhangs have been frequently recommended to reduce collisions. However, there are many situations in which overhangs do not eliminate reflections and only block glass from the view of birds flying above. They are thus of limited effectiveness as a general strategy. Overhangs work best when glass is shadowed from all sides. Functional elements such as balconies and balustrades can block the view of glass, protecting birds while providing an amenity for residents.

Angled Glass



In a study (Klem et al., 2004) comparing bird collisions with vertical panes of glass to those tilted 20 or 40 degrees, the angled glass resulted in less mortality. Klem speculated that this was because the glass reflected the ground, not vegetation. Using angled glass has become a common recommendation as a bird-friendly feature. However, while angled glass may be useful in special circumstances, the birds in the study were flying parallel to the ground from nearby feeders, hitting the glass at acute angles, with less force than a perpendicular strike. In most situations, however, birds may approach glass from any angle.

Patterns on Glass

Ceramic dots, other types of "frits," and other materials can be screened, printed, or otherwise applied to glass surfaces. This is often done to reduce the transmission of light and heat and can also provide design detail. In some cases, frit patterns are hardly visible, but when designed according to the 2 x 4 rule (see p. 47), patterns on glass can also prevent bird strikes. Patterns on the outside surface of glass deter collisions most effectively because they are always visible, even with strong reflections. This type of design, useful primarily for new construction, is currently more common in Europe and

A custom frit pattern was designed by Ennead Architects for Vassar College's Bridge for Laboratory Sciences building. Elements of the pattern occur on two separate surfaces, increasing visibility to birds in flight, who will see a constantly changing pattern that may appear to move. Photo by Christine Sheppard, ABC

Frit patterns behind highly reflective glass may not always be visible. However, in buildings like Skidmore Owings Merril's Cathedral of Christ the Light, the frit pattern is always visible and the pattern should appear as a virtual barrier, deterring birds from flying into it. Photo by Christine Sheppard, ABC

While some internal fritted glass patterns can be overcome by reflections, Frank Gehry's IAC headquarters in Manhattan is so dense that the glass appears opaque. Photo by Christine Sheppard, ABC

Ornilux Mikado's pattern reflects UV wavelengths. The spiderweb effect is visible only from very limited viewing angles. Photo courtesy of Arnold Glass

Asia, but is being offered by an increasing number of manufacturers in the United States. New technologies allowing printing of ceramic inks on the outside surface of glass may greatly increase options for bird-friendly design in the U.S.

More commonly, frit is applied to an internal surface of insulated glass units. This type of design may not be visible if the amount of light reflected by the frit is insufficient to overcome reflections on the outside surface of the glass or if frit is applied as dots below the visual threshold of birds. Some internal frits may only help break up reflections when viewed from some angles and in certain light conditions. However, with the right combination of surface reflectivity and frit application, a pattern on an inside surface can still be effective. The headquarters of the internet company IAC in New York City, designed by Frank Gehry, is composed entirely of fritted glass, most of high density and always visible. No collision mortalities have been reported at this building after two years of monitoring by New York City Audubon. FXFOWLE's Jacob Javits Center, also in Manhattan, reduced collisions by as much as 90% with a renovation that eliminated some dangerous glass and replaced other glass with a visible frit pattern. Another example of a visible internal frit pattern is seen in Skidmore Owings Merril's Cathedral of Christ the Light in Oakland, California.

UV Patterned Glass

Songbirds, gulls, parrots, and other birds can see into the ultraviolet (UV) spectrum of light, a range largely invisible to humans (see page 41). Other bird types, including raptors, kingfishers, hummingbirds, and pigeons, are less sensitive to UV. Ultraviolet reflective and/or absorbing patterns "invisible to humans but visible to birds" are frequently suggested as the optimal solution for many bird collision problems, but few such products are available commercially as of 2015. Progress in development of bird-friendly UV glass has been slow, but with legislation in multiple locations mandating bird-friendly design, glass manufacturers and distributors, as well as window-film manufacturers, are taking an active role in developing new solutions for this application. Research indicates that UV patterns need strong contrast to be effective, especially in the early morning and late afternoon, when UV in sunlight is at low levels. However, UV patterns may be ineffective for many species that have been reported as victims of collisions with glass, including hummingbirds, flycatchers, American Woodcock, and woodpeckers.

Opaque and Translucent Glass

Opaque, etched, stained, or frosted glass and glass block are excellent options to reduce or eliminate collisions, and many attractive architectural applications exist. They can be used in retrofits but are more commonly used in new construction. Frosted glass is created by acid etching or sandblasting transparent glass. Frosted areas are translucent, but various finishes are available with differing levels of light transmission. An entire surface can be frosted, or frosted patterns can be applied. Patterns should conform to the 2 x 4 rule described on page 47. For retrofits, glass also can be frosted by sandblasting on site. Stained glass is typically seen in relatively small areas but can be extremely attractive and is not conducive to collisions. Glass block is versatile, can be used as a design detail or primary construction material, and is also unlikely to cause collisions. Another promising material is photovoltaic glass, which has been used in stained-glass windows and highway noise barriers. This solution is especially interesting, because

The Wexford Science and Technology Building in Philadelphia, designed by Zimmer, Gunsul, Frasca, uses translucent glass to provide light without glare, making it safe for birds. Photo courtesy of Walker Glass

transparent highway noise barriers can cause collisions, and such barriers are beginning to be installed in the United States.

Window Films

Most patterned window films were initially intended for use inside structures as design elements or for privacy. Now, outside surface applications intended to reduce bird collisions are coming onto the market, and some have proved highly effective and popular. The oldest such product creates an opaque white surface on the outside of glass that still permits viewing from the inside. Patterns can be printed on this material, although images of trees and other habitat are not recommended.

A film with a pattern of narrow, horizontal stripes has eliminated collisions at the Philadelphia Zoo Bear Country exhibit for over five years (see photo opposite) and has been similarly successful in other installations when applied to outside surfaces of glass. In these cases, the response has been positive. Another option is to apply vinyl patterns like window film but with the transparent backing removed.

A Zen Wind Curtain is an inexpensive but extremely effective way to deter collisions. Lengths of parachute cord or similar materials are strung vertically, every four inches, in front of problem glass, creating both a visual and a physical barrier. Photo by Glenn Phillips, ABC

Solutions Applied to Interior Glass

Light colored shades have been recommended as a way to deter collisions. However, when visible, they do not effectively reduce reflections, and reflections may make them completely invisible. Closed blinds have the same problems, but if visible and partly open, they can produce the appearance of a 2 x 4 pattern. If an exterior solution is not possible and tape or sticky notes are applied to the inside of windows, be sure to check the windows several times a day to ensure that these materials are visible.

Decals and Tape

Decals are probably the most familiar solution to bird collisions, but their effectiveness is widely misunderstood. Birds do not recognize decals as

This window at the Philadelphia Zoo Bear Country exhibit was the site of frequent bird collisions until window film was applied. Collisions have been eliminated for over five years, with no complaints from visitors about visibility of bears! Photo courtesy of the Philadelphia Zoo

ABC BirdTape

ABC, with support from the Rusinow Family Foundation, has produced ABC BirdTape to make home windows safer for birds. This easy-to-apply tape lets birds see glass while letting you see out, is easily applied, and lasts up to four years. For more information, visit abcbirdtape.org

Photos by Dariusz Zdziebkowski, ABC

silhouettes of falcons, spiderwebs, or other natural objects, but simply as obstacles that they may try to fly around. Decals can be very effective if applied following the 2 x 4 rule on the outside of glass, but in general, they must be replaced frequently, at least annually. Tape is generally more cost effective and quicker to apply, but most household tapes don't stand up well to the elements. Tape intended to last for several years on the outside of windows has become commercially available and is effective when applied following the 2 x 4 guide.

The Consilium Towers, a mirror-glass complex in Toronto, once killed thousands of birds each year. After being taken to court, its owners retrofitted the lower 60 feet of glass with a Feather Friendly dot pattern that has greatly reduced bird mortality.

Reflected in this glass is Michael Mesure, the founder of Toronto's Fatal Light Awareness Program. Photos by Christine Sheppard, ABC

Temporary Solutions

In some circumstances, especially for homes and small buildings, quick, low-cost, temporary solutions, such as making patterns on glass with paint, stickers, or even post-its, can be very effective in the short term. Even a modest effort can reduce collisions. Such measures can be applied when needed and are most effective following the 2 x 4 rule. (For more information, see ABC's flyer "You Can Save Birds from Flying into Windows" and other sources at collisions.abcbirds.org).

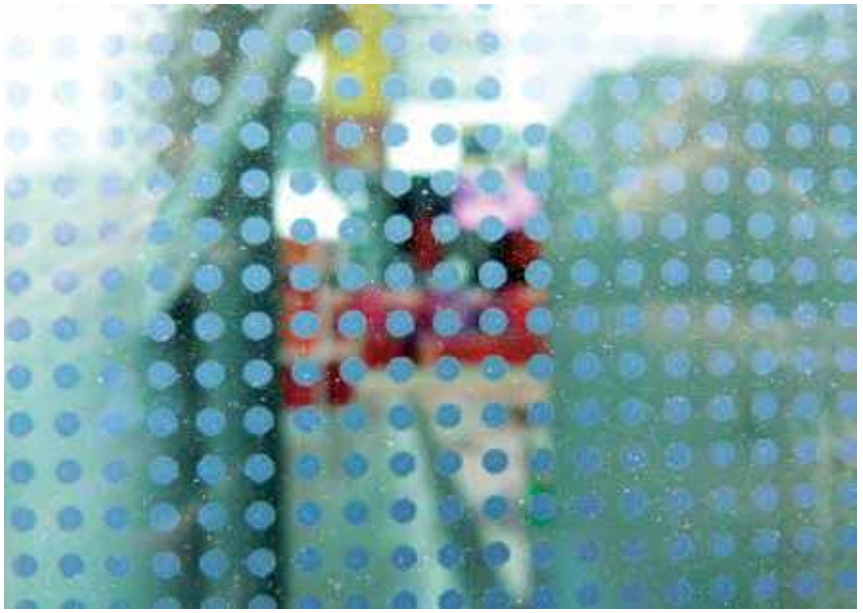
REMEDIATION CASE STUDY: Javits Center

In 2009, the New York City Audubon Society identified the Jacob K. Javits Convention Center as having one of the highest bird-collision mortality rates in New York City.



A major renovation and expansion, designed by the bird-friendly architectural firm of FXFOWLE, was completed in 2014. Some especially deadly glass at street level was replaced with opaque panels. Large panes of clear fritted glass with varying surface characteristics were brought to the site and compared to find the right combination for birds and people.

A 6.75-acre green roof, with adjacent translucent glass, crowns the building and is already providing resources for birds.

Best of all, collisions at the now much larger site have been reduced by 90%.

From a distance, the Javits Center looks like a potential threat to birds.

At close range, a visible pattern of frit dots breaks up reflections, making the glass safe for birds.

Light: Problems and Solutions

Fixtures such as these reduce light pollution, saving energy and money and reducing negative impacts on birds. Photo by Dariusz Zdziebkowski, ABC

Birds evolved complex complementary systems for orientation and vision long before humans developed artificial light. We still have much more to learn, but recent science has begun to clarify how artificial light poses a threat to birds, especially nocturnal migrants. Although most glass collisions take place during daylight hours, artificial lighting at night plays a role in the number and distribution of collisions across the built environment. Unfortunately, the details of how birds respond to night lighting are less well understood than has been commonly believed.

Many collision victims, especially songbirds, are ordinarily active by day and have eyes specialized for color vision and bright light. But although they migrate at night, these birds have poor night vision. Instead, they have magnetic senses that allow them to navigate using the Earth's magnetic field. One of these is located in the retina and requires dim blue natural light to function. Red wavelengths found in most artificial light have been shown to disrupt that magnetic sense. Studies in Germany and Russia have documented birds flying through beams of light and diverting from their course anywhere from a few degrees to a full circle. Areas with significant light pollution may be completely disorienting to birds.

Birds are attracted to relative brightness, and by day often orient toward the sun. If a songbird flies into a home, darkening the room and opening a bright window is the best way to release it. Birds are thought to be attracted to artificial light at night, but we don't know what light level at what distance is sufficient to cause attraction or other behavioral impacts. Gauthreaux and Belser, discussing impacts of night lighting on birds, speculated that in fact, birds affected by night lighting may simply be on course to pass over the lights, not necessarily attracted from a distance. Marquenie and Van de Laar, studying birds and lights on a drilling rig in the North Sea, estimated that when all the lights on the platform were lit, they affected birds up to 3 to 5 kilometers away, causing many to circle the platform.

The science is inconclusive: Lights may only impact birds as they end a migratory stage and come down close to the built environment, or lights may divert birds that would ordinarily pass by. Bad weather can cause birds to fly lower and closer to lights, while also eliminating any visual cues. The interactions that produce correlations between building light emissions and collisions may take place at relatively close range. Once birds come close to a light source, the electromagnetic radiation actively interferes with their magnetic orientation mechanism.

Overly lit buildings waste electricity and increase greenhouse gas emissions and air pollution levels. They also pose a threat to birds. Photo by Matthew Haines

Examples of Acceptable/Unacceptable Lighting Fixtures

Reprinted courtesy of DarkSkySociety.org

Some combination of attraction and disorientation may result in larger numbers of birds in the vicinity of brighter buildings and thus, by day, in more collisions. Interestingly, there seem to be no reports of lights attracting or disorienting migrants as they take off on a new migratory stage.

There has been a tendency to associate collision events with very tall structures, though published reports clearly document impact from light at all levels. Early reports of this phenomenon came from lighthouses. Contemporary reports of light-associated circling events are common at oceanic drilling rigs, and disoriented birds have been reported at night skiing sites. A study in Toronto, using the number of lighted windows on a series of buildings as an index of emitted light, found that the amount of light emitted, not the height of the building, was the best predictor of bird mortality.

Solutions

Poorly designed or improperly installed outdoor fixtures add over $1 billion to electrical costs in the United States every year, according to the International Dark Skies Association. Recent studies estimate that over two-thirds of the world's population can no longer see the Milky Way, just one of the nighttime wonders that connect people with nature. Glare from poorly shielded outdoor light fixtures decreases visibility and can create dangerous conditions, especially for older people, and recent studies suggest that long-term exposure to night lighting can increase the risk of breast cancer, depression, diabetes, obesity, and sleep disorders. Together, the ecological, financial, and cultural impacts of excessive building lighting are compelling reasons to reduce and refine light usage.

Reducing exterior building and site lighting has proven effective at reducing mortality of night migrants at

individual buildings, but achieving overall reduction in collisions will require applying those principles on a wider scale. At the same time, these measures reduce building energy costs and decrease air and light pollution. Efficient design of lighting systems plus operational strategies to reduce light trespass or "spill light" from buildings while maximizing useful light are both important strategies. In addition, an increasing body of evidence shows that red light and white light (which contains red wavelengths) particularly confuse birds, while green and blue light may have far less impact.

Light pollution is largely a result of inefficient exterior lighting, and improving lighting design usually produces savings greater than the cost of changes. For example, globe fixtures permit little control of light, which shines in all directions, resulting in a loss of as much as 50% of energy, as well as poor illumination. Cut-off shields can reduce lighting loss and permit use of lower powered bulbs. Most "vanity lighting" is unnecessary. However, when it is used, down-lighting causes less trespass than up-lighting. Where light is needed for safety and security, reducing the amount of light trespass outside of the needed areas can help by eliminating shadows. Spotlights and searchlights should not be used during bird migration. Communities that have implemented programs to reduce light pollution have not found an increase in crime.

Using automatic controls, including timers, photosensors, and infrared and motion detectors, is far more effective than relying on employees turning off lights. These devices generally pay for themselves in energy savings in less than a year. Workspace lighting should be installed where needed, rather than in large areas. In areas where indoor lights will be on at night, minimize perimeter lighting and/or draw shades after dark.

Switching to daytime cleaning of office buildings is a simple way to reduce lighting while also reducing costs.

Lights Out Programs

Despite the complexity of reducing bird collisions with glass, there is one simple way to decrease mortality: turn lights off. Across the United States and Canada, "Lights Out" programs at the municipal and state levels encourage building owners and occupants to turn out lights visible from outside during spring and fall migration. The first of these, Lights Out Chicago, was started in 1995, followed by Toronto in 1997. The programs themselves are diverse. Some are directed by environmental groups, others by government departments, and still others by partnerships of organizations. Participation in most, such as Houston's, is voluntary. Minnesota mandates turning off lights in state-owned and leased buildings.

Powerful beams of light, even in a landscape of urban light pollution, can entrap migrating birds, seen here circling in the beams of the 9/11 Memorial Tribute in Light in New York City. Because birds may circle for hours, monitors watch all night, and the light beams are temporarily turned off to release large accumulations of birds. Photo by Jason Napolitano

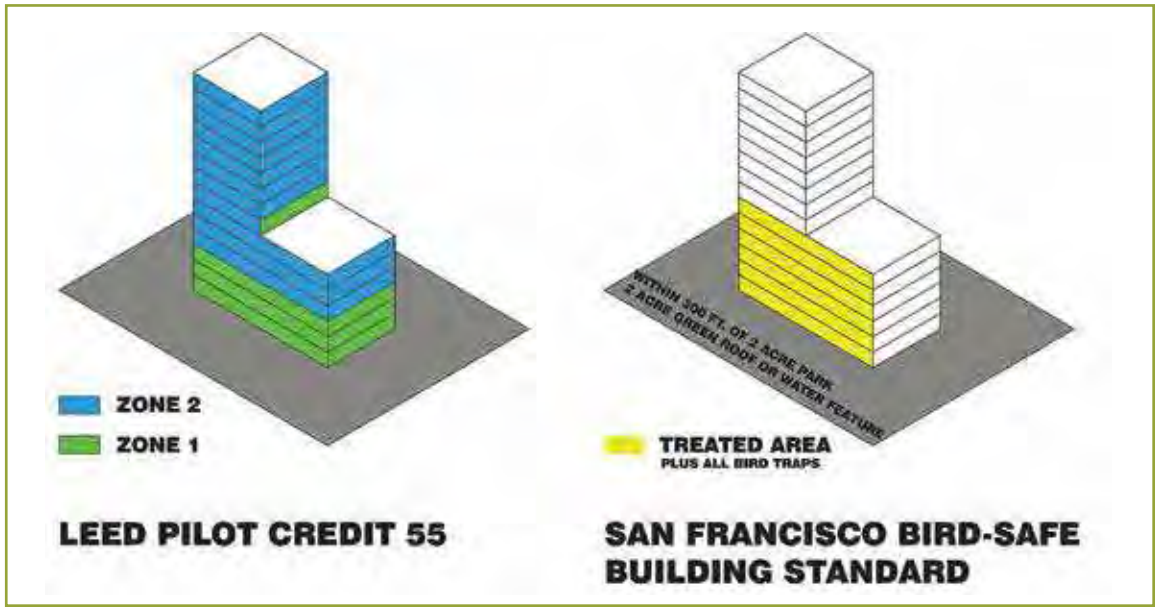
Many jurisdictions have monitoring components. Monitoring programs can provide important information in addition to quantifying collision levels and documenting solutions. Ideally, lights-out programs would be in effect year-round and be applied widely, saving birds and energy costs and reducing emissions of greenhouse gases. ABC stands ready to help develop new programs and to support and expand existing programs.

Solutions: Policy

Legislation

Changing human behavior is generally a slow process, even when the change is uncontroversial. Legislation can be a powerful tool for modifying behavior. Conservation legislation has created reserves, reduced pollution, and protected threatened species and ecosystems. Policies that promote bird-friendly design and reduction of light pollution have recently proliferated across the United States and Canada, following the early examples of Toronto and San Francisco. They vary considerably in scope and detail, often reflecting local politics. (A real-time database of ordinances and other instruments mandating or promoting bird-friendly action, including links to source language, can be found at collisions.abcbirds.org).

An early challenge in creating effective legislation was the lack of objective measures that architects could use to accomplish their task. For example, a common recommendation, to "increase visual noise," because it was unquantified and undefined, made it difficult for architects and planners to know whether a particular design complied with requirements. Material testing (see p. 45) has made it possible to assign relative threat factors to various building façade materials and to use those scores to create quantitative guidelines and mandates.



The illustration to the right broadly compares San Francisco's Bird-safe Building Standard with LEED Pilot Credit 55, both based on the use of materials with quantified threat levels. San Francisco's standard applies generally to new construction and is restricted to façades within 300 feet of a two-acre park or pond. The LEED credit is intentionally very flexible. It applies to all building facades and allows for restricted amounts of high-threat glass, or larger amounts of bird-friendly glass. Because birds are found throughout the built environment, ABC prefers the LEED model. (ABC's model legislation can be found on page 35.)

Bird lovers across the country are proposing bird-friendly design ordinances at both local and state levels. ABC is ready to actively support such efforts. Both mandatory and voluntary instruments can be effective. Voluntary guidelines are easier to modify if they prove to have unintended consequences and can lead to a mandate, but can also be ignored. Generally ABC recommends mandatory guidelines, beginning with a small subset of buildings and expanding as community support increases and resistance decreases.

Incorporating bird-friendly design issues into local sustainability policies is another way to drive change. An interesting example of this is the Fairfax County, Virginia, proffer system. New construction projects are required to address a series of sustainability issues, including potential bird mortality, and either to describe

For its new Visitors Center in Sempach, opened in May 2015, the Swiss Ornithological Institute designed a mandala from bird silhouettes (below) that was applied on the inside of all glass using digital printing. The design provides 40-50% coverage and generates much discussion among visitors, an achievement second only to preventing bird collisions.

Photos by Hans Schmid

how these will be addressed by the project or explain why such action is not possible.

Priorities for Policy Directives

ABC generally recommends against attempting to map locations where bird-friendly design is required because birds can be found in almost every environment, even in seemingly inhospitable ones. However, there may be occasions when it is necessary to compromise on the scope of legislation. In such cases, it must be recognized that proximity to undeveloped land, agricultural areas, parks, and water often correspond to increased bird populations and therefore increased risk of collisions. In addition, areas located in between landscape features desirable to birds may also pose higher risks. For example, in New York City some evidence suggests that birds approach Central Park from due south during spring migration, creating a greater risk zone directly south of the park. Also, building features such as green roofs should be considered when determining greater risk zones for policy purposes.

Sustainability Rating Programs

Another driver of bird-friendly policies consists of sustainability rating programs like the Green Building Council's LEED program, Green Globes, Living Building Challenge, and others. There is general agreement that sustainable buildings should not kill birds. This tenet appears with differing levels of robustness in different systems, with the most specific being the LEED program, which grants Pilot Credit 55: Bird Collision Deterrence. The credit is calculated using a weighted average of the relative threat rating of each material on a building's façade. The credit has attracted a lot of attention, with many projects applying for it. The new Vassar Bridge for Laboratory Sciences on the cover of this publication was one of the first to be designed with the credit in mind and to earn the credit.

Because a number of glass-walled buildings have been awarded LEED certification at the highest level, at one point there was concern that sustainable design was not compatible with bird-friendly design. This was ironic, as in addition to providing natural light, glass on sustainable buildings is intended to link people inside with the natural world outside. However, according to both ASHRAE and ICC, costs for heating and cooling increase when total glass surface exceeds 30-40% of the total building envelope, depending on climate. This is more than sufficient for providing light and views when glass placement is considered thoughtfully. This is a great place to start the design of a bird-friendly structure.

The façade of the WÜRTH Building in Switzerland is mostly glass, laminated with a fabric that is black on the inside but aluminium-coated outside. The inner surface delivers good visibility, and the fabric provides shade and interesting visual effects outside. Preliminary studies by the Swiss Ornithological Institute suggest that the materials used in this building may also deter bird collisions. Photo by Hans Schmid

Model Ordinance for Bird-Friendly Construction

[ORDINANCE Name] Sponsored by: [list names]

WHEREAS, birds provide valuable and important ecological services,

WHEREAS, [location] has recorded [ ] species of resident and migratory bird species,

WHEREAS, birding is a hobby enjoyed by 64 million Americans and generates more than $40 billion a year in economic activity in the United States,

WHEREAS, as many as one billion birds may be killed by collisions with windows every year in the United States,

WHEREAS, reducing light pollution has been shown to reduce bird deaths from collisions with windows,

WHEREAS, new buildings can be designed to reduce bird deaths from collisions without additional cost,

WHEREAS, there exist strategies to mitigate collisions on existing buildings,

WHEREAS, more than 30% glass on a façade usually increases costs for heating and cooling

WHEREAS, bird-friendly practices often go hand-in-hand with energy efficiency improvements,

And WHEREAS [any additions specific to the particular location]

NOW, THEREFORE, BE IT ORDAINED, by [acting agency] [title of legislation and other necessary language]

(a) In this section the term "Leadership in Energy and Environmental Design (LEED)" means a green building rating system promulgated by the United States Green Building Council (USGBC) that provides specific principles and practices, some mandatory but the majority discretionary, that may be applied during the design, construction, and operation phases, which enable the building to be awarded points from reaching present standards of environmental efficiency so that it may achieve LEED certification from the USGBC as a "green" building.

b) [acting agency] does hereby order [acting department] to take the steps necessary to assure that all newly constructed buildings and all buildings scheduled for capital improvement are designed, built, and operated in accordance with the standards and requirements of the LEED Green Building Rating System Pilot Credit 55: Bird Collision Deterrence.

(c) The USGBC releases revised versions of the LEED Green Building Rating System on a regular basis; and [acting department] shall refer to the most current version of the LEED when beginning a new building construction permit project or renovation.

(d) New construction and major renovation projects shall incorporate bird-friendly building materials and design features, including, but not limited to, those recommended by the American Bird Conservancy publication *Bird-Friendly Building Design*.

(e) [acting department] shall make existing buildings bird-friendly where practicable.

The Science of Bird Collisions

Hundreds of species of birds are killed by collisions. These birds were collected by monitors with FLAP in Toronto, Canada. Photo by Kenneth Herdy

Magnitude of Collision Deaths

The number of birds killed by collisions with glass every year is astronomical. Quantifying mortality levels and impacts on populations has been difficult, however. Until recently, local mortality studies—despite producing valuable information—aimed more at documenting mortality than quantifying it, and did not follow rigorous protocols. Loss *et al*. (2012) created methodology and techniques of analysis to determine the magnitude of anthropogenic mortality, using existing data sets. The authors comprehensively acquired published and unpublished data sets on collisions with buildings (Loss *et al*., 2013). Data sets were filtered using a variety of criteria to ensure that they could be used in single analyses. Loss *et al*. (2014b) have also comprehensively described how to collect meaningful data on collisions.

The authors calculated the median annual mortality at homes at 253 million, or 2.1 birds per structure. Urban residences without feeders account for 33% of this mortality cumulatively, as there are more such residences, even though residences with feeders produce more collisions individually. Rural residences without feeders account for 31% of residential mortality, followed by urban residences with feeders (19%) and rural residences with feeders (17%). Median mortality at low-rise buildings (4 to 11 stories), calculated from two data sets, was averaged as 339 million, or 21.7 birds per building. High-rises, although collectively causing the least mortality (508,000), individually had the highest median rate of 24.3 bird collisions per building. Combining all building classes produces an estimate of 365 and 988 (median 599) million birds killed annually in the United States.

Machtans, *et al*. (2013) estimated that about 25 million (ranging from 16 to 42 million) birds are killed by colliding with windows in Canada annually, with 90% of building-related mortalities caused by houses, slightly less than 10% by low-rise buildings, and approximately 1% by tall buildings. In both cases, the total mortality caused by houses is a function of their large number compared to the two other classes of buildings.

Previously, Dunn (1993) surveyed 5,500 people who fed birds at their homes and recorded window collisions. She derived an estimate of 0.65-7.7 bird deaths per home per year for North America. Klem (1990) estimated that each building in the United States kills one to 10 birds per year. Using 1986 U.S. census data, he combined numbers of homes, schools, and commercial buildings for a maximum total of 97,563,626 buildings, producing an estimate of 100 million to one billion birds killed annually.

Klem *et al*. (2009a) used data from New York City Audubon's monitoring of 73 Manhattan building façades to estimate 0.5 collision deaths per acre per year in urban environments, for a total of about 34 million migratory birds annually colliding with city buildings in the

This Barn Swallow illustrates the type of acrobatic flying that may keep swallows from being frequent collision victims. If birds do identify glass as a barrier at close range, perhaps by sound or air movements, most species may be unable to react fast enough to avoid striking the surface. Photo by Keith Ringland

A sample of collision victims from Baltimore.

Sharp-shinned Hawk. Photo by Ted Ardley

United States. However, there could be major differences in collision patterns in cities across the United States, and these numbers should be confirmed using data from additional locations.

In *The American Bird Conservancy Guide to Bird Conservation* (Lebbin *et al.*, 2010) the authors state "…we have reached a point in history when the impacts of human activities are so profound and far-reaching that from now on, it will always be impossible to untangle the completely natural declines from those that are partially or completely anthropogenic. From a conservation standpoint, it is largely irrelevant, anyway. Any human-caused stress that we can alleviate from a declining species can potentially benefit its population, and we should take action to lessen that stress if we can." This is abundantly true for bird mortality from glass because there are actions that many, if not most, individuals can take themselves, directly, to reduce the toll taken by existing glass.

Patterns of Mortality

It is difficult to get a complete and accurate picture of avian mortality from collisions with glass. Collision deaths can occur at any time of day or year. Monitoring programs focus on cities, and even intensive monitoring programs cover only a portion of a city, usually visiting the ground level of a given site at most once a day and often only during migration seasons. Many city buildings have stepped roof setbacks that are inaccessible to monitoring teams. Some studies have focused on reports from homeowners on backyard birds (Klem, 1989; Dunn, 1993) or on mortality of migrants in an urban environment (Gelb and Delacretaz, 2009; Klem *et al.*, 2009a; Newton, 1999). Others have analyzed collision victims produced by single, large-magnitude incidents (Sealy, 1985) or that have become part of museum collections (Snyder, 1946; Blem *et al.*, 1998; Codoner, 1995). There is general support for the fact that birds killed in collisions are not distinguished by age, sex, size, or health (for example: Blem and Willis, 1998; Codoner, 1995; Fink and French, 1971; Hager *et al.*, 2008; Klem, 1989), but the majority of work has focused on data taken during migratory periods, primarily east of the Mississippi River.

Species at Risk

Snyder (1946), examining window collision fatalities at the Royal Ontario Museum, noted that the majority were migrants and "tunnel flyers"—species that frequently fly through small spaces in dense, understory habitat. Conversely, resident species well adapted to and common in urban areas, such as the House Sparrow and European Starling, are not prominent on lists of fatalities, possibly because individuals surviving their first collision may teach offspring to avoid windows.

It is well known that zoo birds in exhibits with glass walls can and do learn about specific pieces of glass, but birds do not learn about glass as a general concept.

Dr. Daniel Klem maintains running totals of the number of species reported in collision events in countries around the world. (This information can be found at http://tinyurl.com/ob3nc4s). In 2015, the site identifies 868 species globally, with 274 from the United States. The intensity of monitoring and reporting programs varies widely from country to country, however.

Hager *et al.* (2008) compared the number of species and individual birds killed at buildings at Augustana College in Illinois with the density and diversity of bird species in the surrounding area. The authors concluded that the

total window area, the habitat immediately adjacent to windows, and behavioral differences among species were the best predictors of mortality patterns, rather than the mere size and composition of the local bird population. Kahle *et al*. (2015) reached similar conclusions in an analysis of five years of data at the California Academy of Sciences, also finding that migrants do not make up the preponderance of birds killed and that males are overrepresented relative to their abundance in habitats adjacent to the museum. Dunn (1993), analyzing winter data from homes with bird feeders, found that the frequency distribution of birds at the feeders closely paralleled the distribution of species killed by nearby windows. Dunn found few collisions on windows of less than one square meter, and an increase in collisions with an increase in window size.

Species such as the White-throated Sparrow, Ovenbird, and Common Yellowthroat appear consistently on top 10 lists from urban areas. It is possible that these species respond more readily to light and thus are more likely to

Common Yellowthroat. Photo by Owen Deutsch

end migratory stages in the built environment, but this needs to be confirmed. Additionally, Loss *et al*. (2013) noted that Golden-winged Warbler, Painted Bunting, Canada Warbler, Wood Thrush), Kentucky Warbler, and Worm-eating Warbler—species identified as birds of conservation concern—were also disproportionately represented in building kills. Hager (2009) noted that window-strike mortality was reported for 45% of raptor species found frequently in urban areas of the United States and was the leading source of mortality for Sharp-shinned Hawks, Cooper's Hawks, Merlins, and Peregrine Falcons. Because most data on glass collisions are from the eastern half of the United States, these lists are presumably biased toward species occurring in that range.

Characteristics of Buildings

Amount of Glass

From a study of multiple buildings in Manhattan, Klem *et al.* (2009a) concluded that both the proportion and absolute amount of glass on a building façade best predict mortality rates, calculating that every increase of 10% in the expanse of glass correlates to a 19% increase in bird mortality in spring and 32% in fall. How well these equations predict mortality in other cities remains to be tested. Collins and Horn (2008), studying collisions at Millikin University in Illinois, concluded that total glass area and the presence/absence of large expanses of glass predicted mortality level. Hager *et al.* (2008, 2014) came to the same conclusion, as did Dunn (1993) and Kahle *et al.* (2015). However, the "patchiness" of glass across a façade—how many pieces, their size, how they are separated, etc. (another way of saying "visual noise")—has not yet been explored in detail but could be important.

The façade of the New York Times building, by FXFOWLE and Renzo Piano, is composed of ceramic rods, spaced to let occupants see out while minimizing the extent of exposed glass—good for controlling heat and light, and safe for birds. Photo by Christine Sheppard, ABC

Time of Day

Most monitoring programs focus on early morning hours to document mortality during migration, often starting monitoring routes at dawn, before sidewalks are cleared. This can, however, lead to the misperception that night-flying migrants are crashing into lighted buildings at night, or only in early morning, whereas in fact most collisions take place during the day. It should be noted that "dawn" is a time that varies among species (Thomas *et al.* (2002), with some bird species active before humans start to see light in the sky.

Hager and Craig (2014), in a study of resident population collisions in northwestern Illinois between June and early August, found that 66% of birds died between sunrise and 4:00 p.m., with no collisions between 4:00 p.m. and sunset. Delacretaz and Gelb (2006) found collisions from early morning until mid-afternoon, but with a peak during morning hours. This finding is confirmed by monitoring programs like that of Pennsylvania Audubon, where routes were followed three times in succession early each day, with birds found at each pass (Keith Russell, pers. comm.) and where people living or working in buildings report window strikes through afternoon hours (Olson, pers. comm).

Local Landscape

Gelb and Delacretaz (2006, 2009) evaluated data from collision mortality at Manhattan building façades. They found that sites where glass reflected extensive vegetation were associated with more collisions than glass reflecting little or no vegetation. Of the 10 buildings responsible for the most collisions, four were "low-rise." Klem (2009) measured variables in the space immediately associated with building façades in Manhattan as risk factors for collisions. Both increased height of trees and increased height of vegetation increased the risk of collisions in fall. Ten percent increases in tree height and the height of vegetation corresponded to 30% and 13% increases in collisions in fall. In spring, only tree height had a significant influence, with a 10% increase corresponding to a 22% increase in collisions. Confusingly, increasing "facing area," defined as the distance to the nearest structure, corresponded strongly with increased collisions in spring and with reduced collisions in fall. Presumably, vegetation increases risk both by attracting more birds to an area and by being reflected in glass.

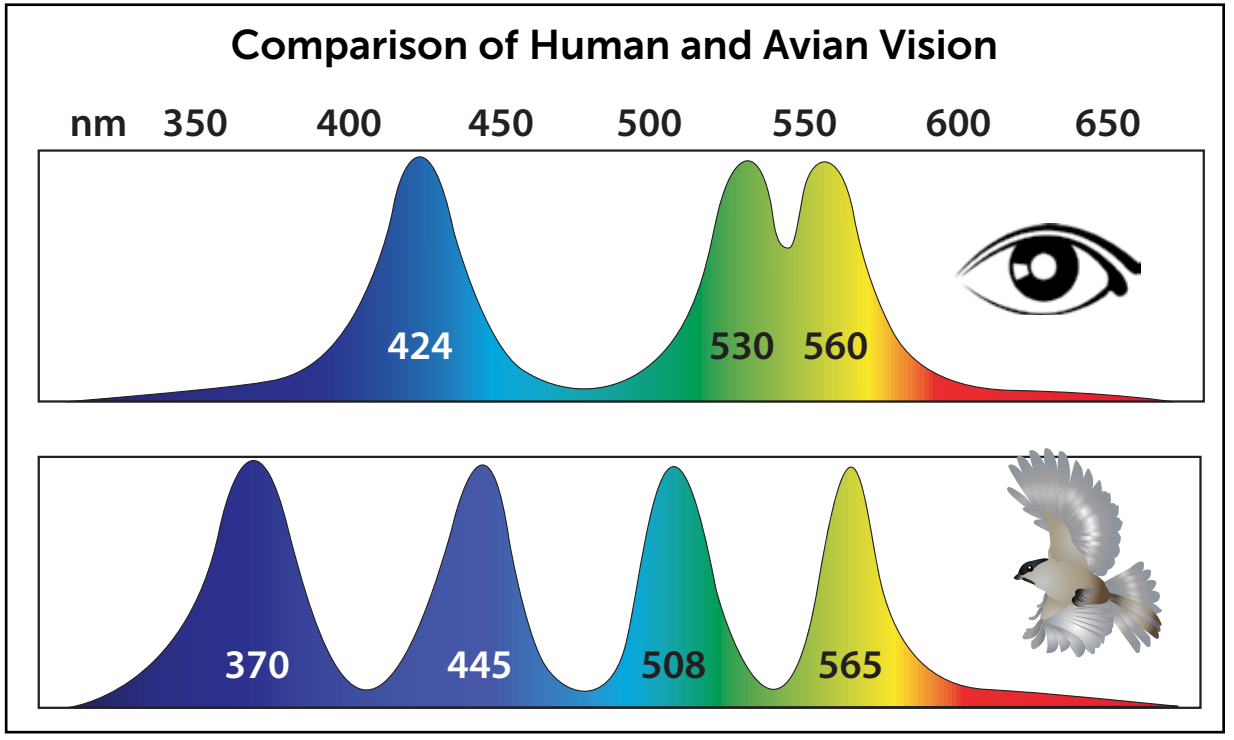
Bayne *et al.* (2012) confirmed that the risk of bird–window collisions varies according to location (urban versus rural, home versus apartment, with or without feeders, and age of neighborhood). They used online surveys and determined that rural residences had more collisions than urban ones and residences with feeders had almost twice as many collisions as those without feeders. For urban dwellings, incidence of collisions increased with age of neighborhood, associated with presence of mature trees. Frequency of collisions varied seasonally: 24% in fall, 35% summer, 25% spring, 16% winter. Mortality patterns were similar: 26% fall, 31% summer, 26% spring, 17% winter. Forty-eight species were reported.

Hager *et al.* (2013) noted that estimates of bird-collision mortality often postulate a relatively constant range of collisions at all buildings (for example, Klem, 1990). However, they suggested that each building in a landscape has its own mortality "signature," based not only on characteristics of the structure but also on the distribution of resources throughout the local landscape, including land cover, habitat type, water, and pavement. Their protocol selected buildings at random and has recently been expanded to multiple other sites across North America.

Avian Vision and Collisions

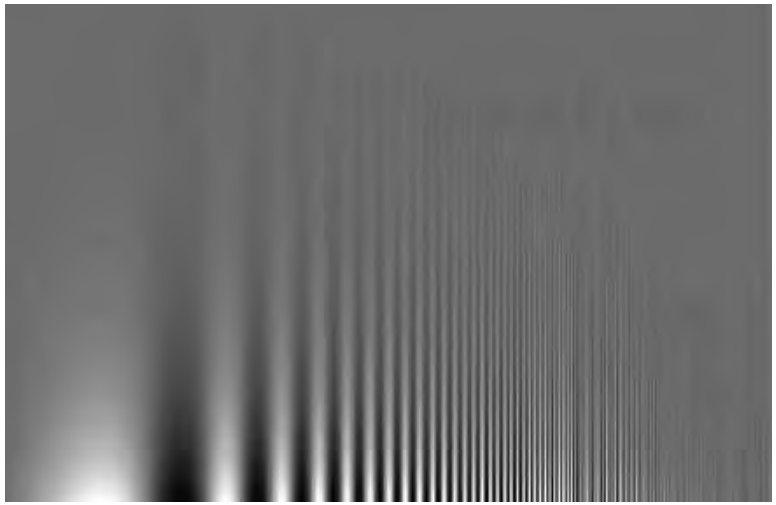
Bird species like falcons are famous for their acute vision, but taking a "bird's-eye view" is much more complicated than it sounds. To start with, where human color vision relies on three types of sensors, birds have four, plus an array of color filters that together allow birds to discriminate between many more colors than people (Varela *et al.* 1993) (see figure this page).

There is also variation in vision among different groups of birds. While some birds see only into the violet range of light, many birds, including most passerines (Ödeen and Håstad, 2003, 2013) see into the ultraviolet spectrum (UVS species).



Ultraviolet can be a component of any color (Cuthill *et al.* 2000). Whereas humans see red, yellow, or red + yellow, birds may see red + yellow, but also red + ultraviolet, yellow + ultraviolet, and red + yellow + ultraviolet—colors for which we have no names. Every object absorbs, reflects, and transmits ultraviolet light along with the other wavelengths in the visible spectrum. UV patterns on glass are often cited as desirable solutions to collisions—visible to birds but not to humans. However, aside from manufacturing complexities, many bird taxa that collide frequently with glass, including raptors, pigeons, woodpeckers, and hummingbirds, may not be able to perceive UV patterns (Håstad and Ödeen, 2014). Additionally, birds are often active in early morning, when UV light levels are low.

Humans and other primates have relatively flat faces, with eyes close together. The overlap of visual fields means that humans have good depth perception and a tendency to focus on what is ahead. Most birds have eyes at the sides of their heads, giving them excellent peripheral vision but poor depth perception, often limited to the length of their beaks, presumably to judge potential food items. They may be much less intent on what is in front of them (Martin 2011, 2012) but able to watch for potential predators to the side or behind them. Many species' most acute vision is to the side. Without much 3D vision, birds use a mechanism called "visual flow fields" to judge their speed and rate of progress in flight by the passage of environmental features to their sides (Bhagavatula *et al.* 2011). Collisions with glass may be partly a result of birds expecting open air ahead, combined with relatively poor forward vision.



Birds process images faster than humans; where we see continuous motion in a movie, birds would see flickering images (D'Eath, 1998; Greenwood *et al.* 2004; Evans *et al.* 2006). This speed helps many birds maneuver quickly in

Painted Bunting. Photo by Ted Ardley

Based on artwork by Sheri Williamson

Contrast sensitivity is a measure of the limit of visibility for low-contrast patterns. Each person's contrast sensitivity can be measured by the extent to which he or she can see the bars that form an arch in this photograph. The exact location of the peak of the curve varies with one's distance from the image; the area within the arch is larger when one is closer. For a given distance, the area under the arch is smaller for birds. Image courtesy of Izumi Ozawa, Berkeley Neuroscience Laboratory

response to unexpected obstacles as they fly through complex habitats. In one respect however—spatial contrast sensitivity—human vision outperforms avian (Ghim and Hodos, 2006). Contrast sensitivity is "the ability of the observer to discriminate between adjacent stimuli on the basis of their differences in relative luminosity (contrast) rather than their absolute luminances." Birds' lack of contrast sensitivity may be an impediment to creating signals to prevent collisions that are effective for birds but not visually intrusive to humans.

Avian Orientation and the Earth's Magnetic Field

In the 1960s, it was discovered that migrating birds possess the ability to orient themselves using cues from the sun, polarized light, stars, the Earth's magnetic field, visual landmarks, and possibly even odors to find their way. Exactly how this works—and it likely varies among species—is still being investigated. (For a comprehensive review of the mechanisms involved in avian orientation, see Wiltschko and Wiltschko, 2009).

The Earth's magnetic field can provide both directional and positional information. It appears that night-flying migrants, and perhaps all bird species, have magnetic field-detecting structures in the retina of the eye that depend on light for function and provide compass orientation. This magnetic sense is wavelength-dependent. Experiments have shown that the compass is disrupted by long wavelength light but requires low-intensity short wavelength light (Wiltschko *et al.* 2007). This research has taken place only in laboratories, and it is important to determine how it translates to the real world.

In addition, anthropogenic electronic noise, found throughout urban environments, has recently been shown to disrupt magnetic compass orientation in European Robins at very low intensities (Engels *et al.* 2014). This finding may have serious implications for strategies aimed at reducing collisions by reducing artificial night lighting alone and should be a priority for additional work.

A second magnetic mechanism, providing birds with positional information, has been postulated, but its details have not been determined. (For a review of magnetoreception and its use in avian migration, see Mouritsen, 2015.)

Birds and Light Pollution

The earliest reports of mass avian mortality caused by lights were from lighthouses, but this source of mortality essentially disappeared when steady-burning lights were replaced by rotating beams (Jones and Francis, 2003). Flashing or interrupted beams apparently allowed birds to continue to navigate, which has also been found more recently at cell towers with strobe lighting (Gehring *et al.* 2009). The emphasis on tall structures by Lights Out programs ignores the fact that light from many sources, from urban sprawl to parking lots, can affect bird behavior and potentially strand birds in the built environment (Gauthreaux and Belser, 2006). Evans-Ogden (2002) showed that light emission levels of 16 buildings, ranging in height from 8 to 72 floors and indexed by the number of lighted windows observed at night, correlated directly with bird mortality, and

that the amount of light emitted by a structure was a better predictor of mortality level than building height, although height was a factor. Parkins *et al.* (2015) made similar findings.

Mass collision events of migrants associated with light and often with fog or storms have been frequently reported (Weir, 1976; Avery *et al.* 1977; Avery *et al.* 1978; Crawford, 1981a, 1981b; Gauthreaux and Belser, 2006; Newton, 2007). But these are no longer the predominant sources of mortality, possibly because the night landscape has changed radically since early reports of mass collision events at tall structures like the Washington Monument and Statue of Liberty. These and other structures were once beacons in areas of relative darkness, but are now surrounded by square miles of light pollution. While collisions at structures like cell towers continue to take place at night, the majority of collisions with buildings now take place during the day. (Hager, 2014; Kahle *et al.*, 2015; Olson, pers. comm.)

Patterns of light intensity seem to play a role in the distribution of collisions in the built environment, however. Birds may land in patterns dictated by the pattern of light intensity in an area, so the brightest buildings are the most likely to cause collisions early in the day. As birds move through the landscape seeking food, patterns related to distribution of vegetation appear. Studies using radar to map movement of birds through the built environment are starting to appear, but we need information at the level of species and individuals to truly understand how light is impacting birds.

It is often said that birds are attracted to lights at night (Gauthreaux and Belser, 2006; Poot *et al.* 2008). However, we do not have direct evidence that birds are, in fact, attracted to lights; they may simply *respond* to lights they encounter. Gauthreaux and Belser quote Verheijen as suggesting that "capture" might be a better word for birds' response to night lighting. While "capture" does seem appropriate to describe the phenomenon of birds circling drilling platforms, or in the lights of the 9/11 Memorial's Tribute in Light in Manhattan, "disorientation" is a term that covers more of the spectrum of behaviors seen when birds interact with light at night. Gauthreaux and Belser (2006), reporting unpublished data, stated that "exposure to a light field causes alteration of a straight flight path (for example hovering, slowing down, shifting direction, or circling)," and this has been reported by other authors.

Larkin and Frase (1988, in Gauthreaux and Belser, 2006) used portable tracking radar to record flight paths of birds near a broadcast tower in Michigan. Birds showed a range of response, from circling to arcs to linear flight. Haupt and Schillemeit (2011) described the paths of 213 birds flying through up-lighting from several different outdoor lighting schemes. Only 7.5% showed no change in behavior, while the remainder deviated from their courses by varying degrees, from minimal course deviation through circling. It is not known whether response differences are species related.

Bolshakov *et al.* (2010) developed the Optical-Electronic Device to study nocturnal migration behaviors of songbirds. Inspired by the more limited techniques of moon watching and watching birds cross ceilometer light beams, the device uses searchlights to illuminate birds from the ground, while a recording unit documents the birds' movements. With this technique, they can study 1) ground- and airspeed; 2) compensation for wind drift on the basis of direct measurements of headings and track directions of individual birds; 3) wing-beat pattern and its variation depending on

wind direction and velocity. In some cases, species can be identified. Bolshakov *et al.* (2013) examined the effects of wind conditions on numbers of birds aloft and flight trajectories of birds crossing the light beam from the apparatus. They determined that numbers of birds do differ with wind strength, but that birds may be attracted to the light beam under calm conditions. They also found that the light beam disturbs straight flight trajectories, especially in calm wind conditions. Regression models suggest that the probability of curved flight trajectories is greater for small birds, especially when there is little or no moon.

Bulyuk *et al.* (2014) used the same device to compare behaviors of night-migrating passerines under natural nocturnal illumination (at the Courish Spit of the Baltic Sea) with birds passing through an urban light environment (inside the city limits of St. Petersburg, Russia). Songbirds were distinguished as either small passerines or thrushes. The illuminated background caused a decrease in image quality. The shape of flight tracks was compared for the two groups, and a larger proportion of small songbirds changed flight path while crossing the light. This could be explained by flight type or flight speed. The proportion of songbirds changing flight trajectory in the lighted condition was much smaller than under the dark condition.

To understand exactly how light affects birds and what actions must be taken to reduce those effects, we need to know much more. For example, at what range (horizontal and vertical) and under what conditions do birds feel disruption from light, and of what intensity and wavelength composition? How do these factors change their behavior? Does night lighting have any effect on birds departing at the beginning of migratory stages? Do we ever actually see birds changing course to move toward a bright light source?

Light Color and Avian Orientation

Starting in the 1940s, ceilometers—powerful beams of light used to measure the height of cloud cover—came into use and were associated with significant bird kills. Filtering out long (red) wavelengths and using the blue/green range greatly reduced mortality, although we don't know whether the intensities of these two colors of lights were equal. Later, replacement of fixed-beam ceilometers with rotating beams essentially eliminated the impact on migrating birds (Laskey, 1960). A complex series of laboratory studies in the 1990s demonstrated that birds required light in order to sense the Earth's magnetic field. Birds could orient correctly under monochromatic blue or green light, but longer wavelengths (yellow and red) caused disorientation (Rappli *et al.,* 2000; Wiltschko *et al.,*1993, 2003, 2007). Wiltschko *et al.* (2007) showed that above intensity thresholds that decrease from green to UV, birds showed disorientation. Disorientation occurs at light levels that are still relatively low, equivalent to less than half an hour before sunrise under clear sky.

Poot *et al.* (2008) demonstrated that migrating birds exposed to various colored lights in the field responded the same way as they do in the laboratory. Birds responded strongly to white and red lights and appeared disoriented by them, especially under overcast skies. Green light provoked less response and minimal disorientation; blue light attracted few birds and did not disorient those that it did attract. Birds were not attracted to infrared light. Evans *et al.* (2007) also tested different light colors but did not see aggregation under red light. However, they subsequently determined that the intensity of red light used was less than for other wavelengths, and when they repeated the trial with higher intensity red, they did see aggregation (Evans, pers. comm. 2011).

Scientists working in the Gulf of Mexico (Russell, 2005), the North Atlantic (Wiese *et al.* 2001), and the North Sea (Poot *et al.* 2008) report that bright lights of oceanic drilling rigs induce circling behavior and mortality in birds at night. Working on a rig in the North Sea, Marquenie *et al.* (2013), estimated that birds were affected up to five kilometers away. Replacing about half the lights with new bulbs emitting minimal red light reduced circling behavior by about 50%. The authors speculate that completely re-lamping the platform would reduce bird aggregation by 90%. Gehring *et al.* (2009) demonstrated that mortality at communication towers was greatly reduced if strobe lighting was used as opposed to steady-burning white, or especially red lights. At the 9/11 Memorial Tribute in Light in Manhattan, when birds aggregate and circle in the beams, monitors turn the lights out briefly, releasing the birds (Elbin, 2015, pers. comm.). Regular, short intervals of darkness, or replacement of steady-burning warning lights with intermittent lights, are excellent options for protecting birds, and manipulating light color also has promise, although additional field trials for colored lights are needed.

Research: Deterring Collisions

Systematic efforts to identify signals that can be used to make glass visible to birds began with the work of Dr. Daniel Klem in 1989. Testing glass panes in the field and using a dichotomous choice protocol in an aviary, Klem (1990) demonstrated that popular devices like "diving falcon" silhouettes were effective only if they were applied densely, spaced two to four inches apart. Owl decoys, blinking holiday lights, and pictures of vertebrate eyes were among items found to be ineffective. Grid and stripe patterns made from white material, one inch wide, were tested at different spacing intervals. Only three were effective: a 3 x 4-inch grid; vertical stripes spaced four inches apart; and horizontal

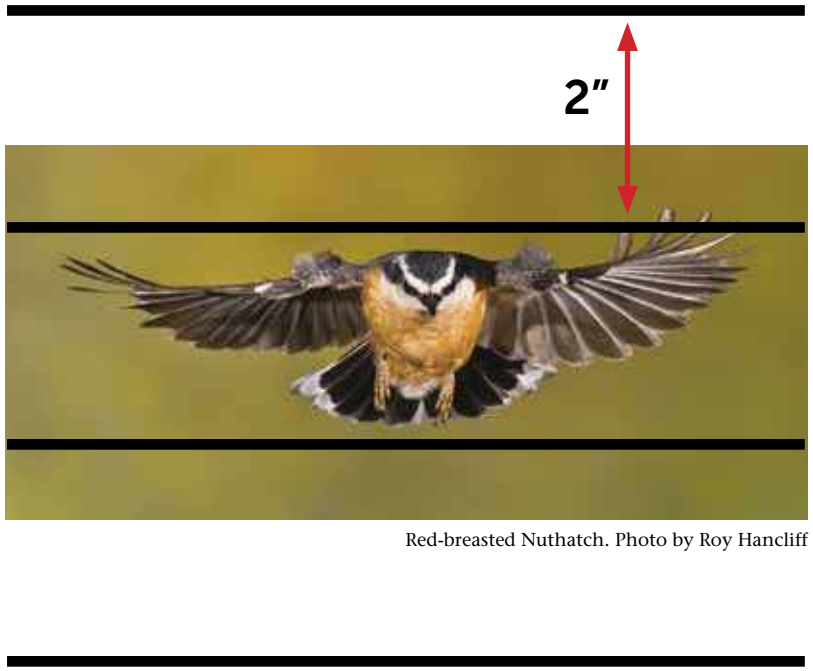
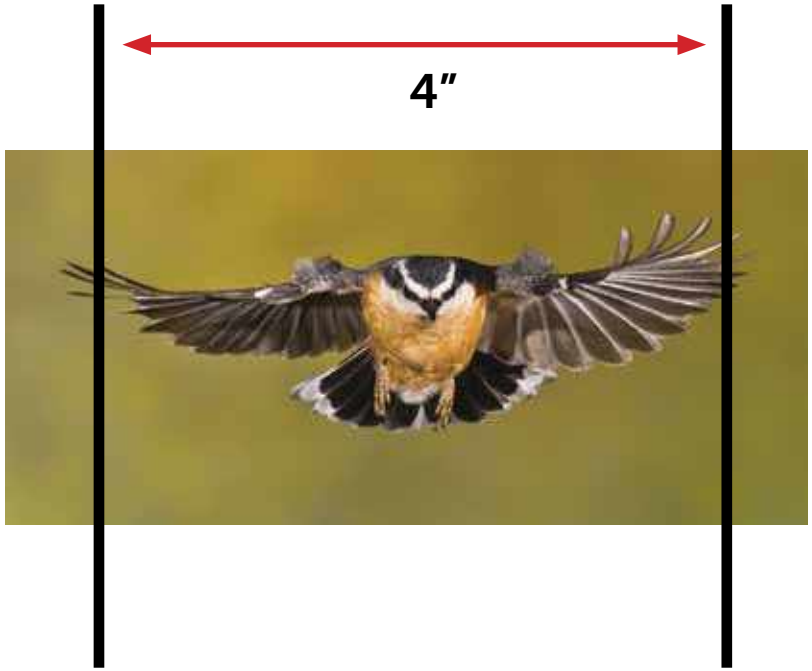
stripes spaced about an inch apart across the entire surface. (A summary of Klem's results can be found at collisions.abcbirds.org).

Building on Klem's findings, Rössler developed a testing program in Austria starting in 2004 and continuing to the present (Rössler and Zuna-Kratky, 2004; Rössler, 2005; Rössler, *et al.,* 2007; Rössler and Laube, 2008; Rössler, 2010; Rössler, 2012; Rössler, 2013). The banding center at the Hohenau Ringelsdorf Biological Station outside Vienna, Austria, offered a large sampling of birds for each test, in some instances permitting comparisons of a particular pattern under differing intensities of lighting. This program has focused primarily on geometric patterns, evaluating the impact of spacing, orientation, and dimensions. Birds are placed in a "tunnel," where they can view two pieces of glass: one unmodified (the control) and the other with the pattern to be tested. Birds fly down the tunnel and are scored according to whether they try to exit through the control or the patterned glass. A mist net keeps the bird from hitting the glass, and it is then released. The project focuses not only on finding patterns effective for deterring collisions, but also on effective patterns that cover a minimal part of the glass surface. To date, some patterns that cover only 5% of the glass have been found to be highly effective. (A summary of Rössler's results can be found at collisions.abcbirds.org).



The tunnel at Powdermill, showing the framework where the background will be mounted. Photo by Christine Sheppard, ABC

Building on Rössler's work, ABC collaborated with the Wildlife Conservation Society, New York City Audubon, and the Carnegie Museum to construct a tunnel at Powdermill Nature Reserve's banding station, primarily to test commercially available materials. Results from the first season showed that making an entire surface UV-reflective was not an effective way to deter birds. With UV materials, contrast seems to be important. Glass fritted in patterns conforming to the 2 x 4 rule, however, scored well as deterrents. (A summary of results from Powdermill can be found at collisions.abcbirds.org).



Most clear glass made in the United States transmits about 96% and reflects about 4% of light falling perpendicular to the outside surface. The amount of light reflected increases at sharper angles: clear glass reflects about 50% of incident light at angles over 70 degrees. Light on the inside of the glass is also partly reflected and partly transmitted. The relative intensities of light transmitted from the inside and reflected from the outside surfaces of glass combined with the viewing angle determine whether the glass appears transparent or mirrors the surrounding environment. Patterns on the inside surfaces of glass and objects inside the glass may not always be visible. These changeable optical properties support the argument that patterns applied to the outer surface of glass are more effective than patterns applied to the inner surface. Efforts have been made to model freestanding glass, glass installed on a building, and reflections on glass in some trials. (The testing protocol for freestanding glass, developed at Hohenau, and the testing protocols used at Powdermill can be found at collisions.abcbirds.org).

Horizontal lines with a maximum spacing of 2 inches

Red-breasted Nuthatch. Photo by Roy Hancliff

Vertical lines with a maximum spacing of 4 inches

The 2 x 4 Rule

Research on songbirds, the most numerous victims of collisions, has shown that horizontal lines must be two or fewer inches apart to deter the majority of birds. Vertical spaces must be four or fewer inches apart. This difference presumably has to do with the shape of a flying bird. (Narrower spacing is required to deter collisions by hummingbirds.) Schiffner *et al.* (2014) showed that budgies have a very precise understanding of their own physical dimensions. Trained to fly in a tunnel, the birds were then challenged to pass through ever narrowing gaps. They were able to assess the width of the gaps relative to their body size and adjust their flight behavior accordingly. It seems likely that this is a general avian trait, useful for navigating complex environments at flight speed. Bhagavatula *et al.* (2011) used the same tunnel setup to investigate how optical flow cues guide flight. It appears that birds balance the speeds of images perceived by both eyes, in this case, images to the birds' sides. This reinforces the suggestion of Martin (2011) that humans experience the world as something ahead of them, while for birds in flight, what is ahead of them is not necessarily their primary focus.

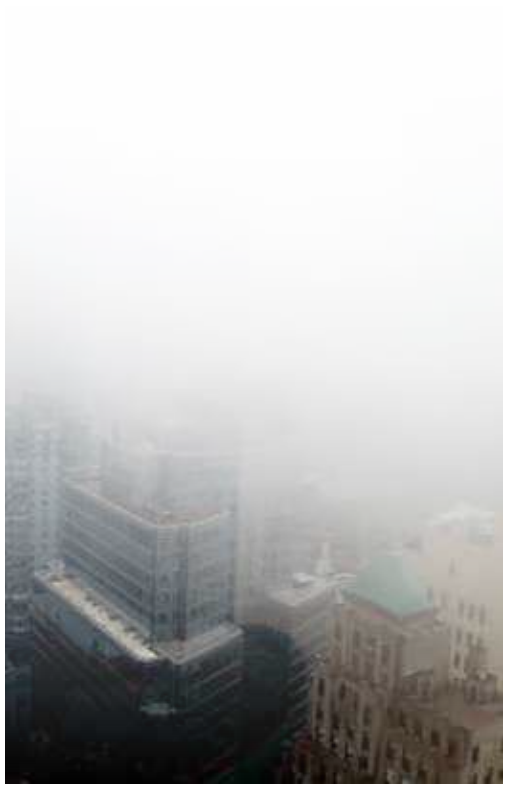
Evaluating Collision Problems—A Toolkit for Building Owners

American Woodcock are often victims of collisions. This bird hit a window in Washington, D.C., in March, 2011, and was recovered by ABC's Jason Berry. Photo by Dariusz Zdziebkowski, ABC

Often, only part of a building is responsible for causing most of the collisions. Evaluation and documentation can help in the development of a program of remediation targeting that area. Remediation can be almost as effective as modifying the entire building, as well as less expensive. Documentation of patterns of mortality and environmental features that may be contributing to collisions is essential. Operations personnel are often good sources of information for commercial buildings, as they may come across bird carcasses while performing regular maintenance activities. People who work near windows are often aware of birds hitting them.

Regular monitoring not only produces data on the magnitude and patterns of mortality, but also provides a baseline for demonstrating improvement. The best monitoring programs feature consistent effort, careful documentation of collision locations, and accurate identification of victims. Effective monitoring should document at least 18 months of collisions before mitigation is attempted, unless collision rates are especially high. (Resources for monitoring, from simple to sophisticated, can be found at collisions.abcbirds.org).

Solutions



Many factors come into play in selecting how to make glass safe for birds. The table below compares common solutions according to their effectiveness, appearance, relative cost, ease of application, longevity, and required maintenance. Effective patterns on the exterior surface of glass will combat reflection, transparency, and passage effect. Within the 2 x 4 guidelines, however, considerable variation is possible when devising bird-friendly patterns. We recommend that lines be at least ¼-inch wide, but it is not necessary that they be only vertical or horizontal. Contrast between pattern and background is important, however, and designers should be aware that the background—building interior, sky, vegetation—may change in appearance throughout the day.

This security grille creates a pattern that will deter birds from flying to reflections. Photo by Christine Sheppard, ABC

Fog increases the danger of light both by causing birds to fly lower and by refracting light so it is visible over a larger area. Photo by Christine Sheppard, ABC

The following questions can guide the evaluation and documentation process by helping to identify features likely to cause collisions and other important factors.

Seasonal Timing

Do collisions happen mostly during migration or fledging periods, in winter, or year round? If collisions happen only during a short time period, it may be possible to apply inexpensive, temporary solutions during that time and remove them for the rest of the year. Some birds will attack their own reflections, especially in spring. This is not a true collision. Territorial males, especially American Robins and Northern Cardinals, perceive their reflection as a rival male. They are unlikely to injure themselves, and temporarily blocking reflections in the offending window (and those nearby) from the outside should resolve the problem. Taping up paper and smearing a soap paste can both be effective.

Weather

Do collisions coincide with particular weather conditions, such as foggy or overcast days? Such collisions may be light-related, in which case an email notification system, asking building personnel to turn off lights when bad weather is forecast, is advisable.

Diurnal Timing

Do collisions happen at a particular time of day? The appearance of glass can change significantly with different light levels, direct or indirect illumination, and sun angles. It may be possible to simply use shades or shutters during critical times.

Lower-floor windows are thought to be more dangerous to birds because they are more likely to reflect vegetation. Photo by Christine Sheppard, ABC

Location

Are there particular windows, groups of windows, or building façades that account for most collisions? If so, it may be cost effective to modify only those sections of glass. Is glass located where birds fly between roosting or nesting and feeding sites? Are there areas where plants can be seen through glass—for example, an atrium, courtyard, or glass building connectors?

Are there architectural or landscaping features that tend to direct birds toward glass? Such features might include a wall or rock outcropping or a pathway bordered by dense vegetation. Solutions include using a screen or trellis to divert flight paths. Are there fruit trees, berry bushes, or other plants near windows that are likely to attract birds closer to glass? These windows should be a high priority for remediation. The glass itself can be modified, but it may also be possible to use live or inanimate landscaping elements to block the view between food sources and windows.

Local Bird Populations

What types of birds are usually found in an area? Local bird groups or volunteers may be able to help characterize local and transitory bird populations, as well as the most likely routes for birds making short flights around the area. The American Birding Association, *Bird Watchers Digest*, Audubon chapters, and Birding.com are good places to start finding such resources. Universities, colleges, and museums may also be helpful.

Post-Mitigation Monitoring

Monitoring efforts should continue for at least 18 months after mitigation efforts are made, and for at least two peak collision seasons (often the fall in urban areas, but spring and summer may also be peak seasons in more rural locations). Collision rates vary along with local bird populations, so a year of high population and high collisions may be followed by a year of low populations and low collisions, regardless of the effectiveness of any mitigation.

Use of glass with a highly effective horizontal frit pattern, together with sunshades, earned this retrofitted building on the SUNY Brockport campus the LEED "collision deterrence" credit. Photo by Paul Tankel

Acknowledgments

American Bird Conservancy (ABC) would like to thank the following for their help in bringing this document to fruition: Susan Elbin and the staff of New York City Audubon, the Wildlife Conservation Society, Bird-safe Glass Foundation, International Dark Skies Association, Fatal Light Awareness Program, Joanna Eckles, Deborah Laurel, Guy Maxwell, Dan Piselli, Bruce Fowle, Marcia Fowle, and Stefan Knust.

We are especially grateful to the Leon Levy Foundation for its ongoing support for ABC's Collisions Program.

This document is based on guidelines published by the New York City Audubon Society, Inc., May 2007, with support from the U.S. Fish & Wildlife Service through the Neotropical Migratory Bird Conservation Act.

American Bird Conservancy is the Western Hemisphere's bird conservation specialist—the only organization with a single and steadfast commitment to achieving conservation results for native birds and their habitats throughout the Americas. With a focus on efficiency and working in partnership, we take on the toughest problems facing birds today, innovating and building on sound science to halt extinctions, protect habitats, eliminate threats, and build capacity for bird conservation.

The Orange Cube, a commercial and cultural complex, was designed by Jacob + McFarlane Architects as part of redevelopment of the harbor in Lyons, France. The external skin virtually eliminates threats to birds while permitting natural illumination of the interior and sightlines for those inside. Photo © Nicolas Borel

American Bird Conservancy's Bird-Friendly Building Standard

The U.S. Green Building Council's LEED Pilot Credit 55 represents the best current understanding of what constitutes a bird-friendly building. Briefly, a bird-friendly building is one where:

- At least 90% of the material in the exposed façade from ground level to 40 feet (the primary bird collision zone) has a threat score of 30 or less, derived from controlled experiments.
- At least 60% of material in the exposed façade above the collision zone meets the above standard.
- All glass surrounding atria or courtyards meets the above standard.
- There are no "see through" passageways or corners.
- Outside lighting is appropriately shielded and directed to minimize attraction to night migrating or nocturnal birds.
- Interior lighting is turned off at night if not in use and designed to minimize light escaping through windows during night operation.
- Landscaping is designed without features known to increase collisions.
- Actual bird mortality is monitored and compensated for (for example, in the form of habitat preserved or created elsewhere, mortality from other sources reduced, etc.).

The Burj Qatar, designed by Jean Nouvel, was named Best Tall Building Worldwide in 2012. The façade, created with multi-layered screens, expresses local culture while providing protection from high temperatures and sand. Photo by Marc Desbordes
